A—When palming and remembering black, one should imagine everything remembered to be moving and not stationary. It is necessary to shift from one image or from one object to another. Shift continually from part to part on objects and object to object on mental pictures in the imagination.

Q—Would the reading of fine print at four inches be helpful?

A—The reading of fine print at four inches is usually helpful.

Q—My little son becomes fidgety while palming. Do you prescribe something else equally beneficial?

A—Your little son may become able to palm for a few minutes at a time. Sometimes swaying from side to side helps.

Q—I am presbyopic (old-age sight). How can I improve my vision by reading fine print, when I can not even see it?

A—You can improve your vision for reading fine print by alternately remembering the whiteness of snow for a second while looking at the white spaces between the lines of print, then close your eyes and remember or imagine the same white more continuously, better and more easily. By alternating, you may become able to remember the white as well when flashing the card, as you can with your eyes closed with improved vision.

Q—I cured myself by following the directions in your book, but cannot seem to benefit my mother. She is nearsighted and doubtful of good results in her case.

A—The fact that you cured yourself by following the directions in my book, makes it possible to cure your mother in the same way. You will waste your time unless your mother has the courage to discard her glasses permanently.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

January, 1925

Sun-Gazing

By W. H. BATES, M.D.

IT is a well-known fact that the constant protection of the eyes from the sunlight, or from other kinds of light, is followed by weakness or inflammation of the eyes or eyelids. Children living in dark rooms, where the sun seldom enters, acquire an intolerance for the light. Some of them keep their eyes covered with their hands, or bury their faces in a pillow and do all they possibly can to avoid exposure of their eyes to ordinary light. I have seen many hundreds of cases of young children brought to the clinic with **ulceration of the cornea**, which may become sufficient to cause blindness. Putting these children in a dark room is a blunder. My best results in the cure of these cases were obtained by encouraging the patients to spend a good deal of the time out of doors, with their faces exposed to the direct rays of the sun. In a short time these children became able to play and enjoy themselves a great deal more out of doors, exposed to the sunlight, than when they protected their eyes from the light. Not only is the sun beneficial to children with inflammation of the cornea, but it is also beneficial to adults.

When the patient looks down sufficiently, the white part of the eye can be exposed by gently lifting the upper lid, while the sun's rays strike directly upon this part of the eyeball. In most cases it is possible to focus the strong light of the sun on the white part of the eyeball with the aid of a strong convex glass, being careful to move the light from side to side quite rapidly to avoid the heat. After such a treatment, the patient almost immediately becomes able to open his eyes widely in the light.

Plain sunlight (without use of the convex glass) is also very effective. Glass filters the light causing unbalanced, unhealthy (not full spectrum) sunlight to contact the eyes. The convex glass is only used by a experienced eye doctor and only in cases of extreme vision impairment, blindness and is not applied too often. Looking at the bright area of the sky on a sunny day, (not directly into the sun) and closed eye sunning while facing directly at the sun are safer alternatives.

Sunning - face the sun, eyes closed, move the head side to side.

Sunlight shining on the sclera, white part of the eye. Person looks down, eyes pupil under the lower eyelid. Upper lid is pulled up to expose the sclera to the sunlight.

## Mental Strain

By W. H. BATES, M.D.

IT can be demonstrated that all persons conscious of imperfect sight have a mental strain. To try to do the impossible is a strain. It is impossible with the eyes closed to remember or imagine a small black area continuously black and stationary. Persons with perfect sight or a perfect memory, when trying to imagine a small black period stationary, notice an effort or mental strain very quickly, in a few seconds or less, while persons with imperfect sight or an imperfect memory may strain for a longer time before they become conscious of as effort. To concentrate the attention on a point for any great length of time usually causes discomfort, fatigue, or pain, in the eyes or elsewhere.

**MYOPIA, or NEAR-SIGHTEDNESS**, is caused by a strain or an effort to see distant objects. It can always be produced in the normal eye temporarily, or more permanently, by trying to see distant objects. With perfect sight the eyes and mind are at rest. All

the sensitive nerves of the body are passive. Myopia is never continuous. At frequent intervals, lasting for a fraction of a second or longer, the patient is conscious of flashes of better vision. To test the facts, the retinoscope is reliable. When a patient with myopia looks at a blank wall without trying to see, or remembers something perfectly, the retinoscope, used at the same time demonstrates that there are, periods of time when the eye is normal. This fact can be demonstrated in all cases. Even patients with thirty or forty diopters of myopia are not myopic all the time. This fact is offered as evidence that myopia, as described by many authors, is not a permanent condition of the eyeball. It can also be demonstrated that when the mind is at rest, and there is no mental strain when the patient remembers or imagines a letter, a color, or some other object perfectly, the myopia disappears. To have imperfect sight from myopia requires much mental effort, time, and trouble to produce it. Every person with myopia has to maintain a mental strain with all its discomforts, in order to maintain a degree of myopia. These facts suggest successful methods of treatment. Since mental strain, or an effort to see distant objects, is the cause of myopia, mental relaxation or rest is followed by benefit. By closing the eyes for five minutes or longer, while letting the mind drift from one thought, or memory, to another, slowly, easily, and continuously, rest of the mind is obtained, and when the eyes are opened, the vision is usually improved for a short time, or for a flash.

Blinking, in which the eyes are opened and closed frequently, is a great help, because the eyes and mind obtain a measure of rest when the eyes are closed, even momentarily. Many patients obtain a greater amount of rest by closing the eyes and covering them with the palms of one or both hands for a few minutes, or longer. We have to consider individuals because, while there are many cases benefited by palming for a half hour or longer, there are others who do better when they palm for a few minutes only, or for short periods of time. Mental strain is usually unconscious. It is a bad habit. When myopic patients learn that they have this unconscious bad habit of mental strain, or when they find out what is the matter with them, it helps in the cure. When patients think it is no fault of theirs that they have imperfect sight, treatment becomes more difficult. To change the unconscious bad habit of mental strain to a habit of relaxation and rest, requires that the patient consciously practices relaxation and rest until the conscious practice by repetition becomes an unconscious habit.

**HYPERMETROPIA, or FAR-SIGHTEDNESS.** The length of the eyeball is shortened in hypermetropia, which is the opposite of myopia in which the eyeball is lengthened by a mental strain to see at the distance. The cause of hypermetropia is a mental strain to see near objects. When a patient reads fine print with normal sight at twelve inches, with the use of the retinoscope at the same time, it can be demonstrated that the eye is accurately focused for twelve inches. But when the patient fails to read perfectly at twelve inches or nearer, he usually feels the discomfort of mental strain, and the retinoscope demonstrates at the same time that the eye is focused for a greater distance than twelve inches. In all cases examined, the mental strain to see near objects produces not myopia, but just the opposite, hypermetropia.

When hypermetropia is not great enough to prevent reading fine print perfectly at a near point, the retinoscope demonstrates that the eyes are accurately focused for that distance. As occurs under similar conditions with normal or myopic eyes, the hypermetropic eye can only read perfectly without a mental effort. If the hypermetropic eye fails to read fine print perfectly, the retinoscope always demonstrates that the eyes are focused for a greater distance. The vision of the hypermetropic eye is improved by the same methods which improve the vision of the myopic eye. Since the cause of hypermetropia is a mental effort, its cure is obtained when the mental effort disappears.

**PRESBYOPIA.** When the vision for the distance remains good, while the ability to read at the near point fails, the condition is called presbyopia. In most text-books, if not all, on the eyes, the statement is made that presbyopia begins soon after the age of forty, and increases gradually until the ability to accommodate is entirely lost. Most ophthalmologists have observed that sometimes presbyopia may begin before the age of forty, or it may not appear until a much later date. I have seen patients over sixty years of age, who had normal sight in each eye for the distance, and the ability to read the diamond type at six inches or less with each eye. A popular belief of the cause of presbyopia is that it is due to hardening of the lens, which prevents the lens from changing its shape. I have quite frequently published facts which demonstrated that the lens was not a factor in accommodation, and that the cause of presbyopia was a mental strain when trying to see or read at a near point. Such patients, when they read the distant test card with normal vision, feel comfortable, but when they plan to read the newspaper or fine print at twelve inches or nearer, they are conscious of mental strain or effort, and the greater the mental strain, the less does the patient see. Presbyopia is cured by practicing relaxation methods. Closing the eyes and resting them for five minutes or longer, may enable some patients to read fine print at twelve inches or less in flashes. Blinking is a benefit to some patients, but not to all. Very gratifying results have followed palming for an hour, or longer, in some cases, while in others palming was a failure. Any method which secures mental relaxation is always a benefit.

Presbyopic patients are often cured quickly by a perfect imagination of the halos, which are the white spaces between the lines of letters that appear whiter than the margin of the page.

*The eyes, when reading perfectly, do not look directly at the letters, but at the white spaces or the halos.*

(Modern teachers state to look directly at the letters (central fixation) when reading. Look at the white spaces to rest the eyes when not reading.) Dr. Bates also states this in other articles.

**ASTIGMATISM is caused by mental strain, and is cured by relaxation of the mental strain.**

## Stories from the Clinic

### No. 59 Mental Strain

By EMILY C. LIERMAN

AT one time a young man, aged twenty-seven years, came to us suffering from severe mental strain. His large staring eyes would make anyone uncomfortable just by looking at him. I approached him in the usual way asking him what his trouble was. He smiled and said:

"Now, that's just what I am trying to find out. Nobody seems to want me. Everybody thinks I am crazy."

I answered, "You are wrong. I don't think you are crazy."

Just the same, this poor fellow did make me feel sort of creepy. I was just a little afraid of him, but did not dare to show it.

He had much to say, but the main thing he wanted me to know was, that he was not insane. When he calmed down a bit, I said, "Now let me say something. I know that you are staring so badly that if you don't stop it, you can easily become insane or blind."

I wanted him to understand that I could not help him, nor anyone else, if he continued staring his eyes out of his head.

I asked Dr. Bates to examine his eyes and to tell me what treatment was best for him. The doctor said there was nothing organically wrong with his eyes, but that he was under a terrible mental strain. I understood very well what was before me when Dr. Bates said, "I think you had better knock on my door if the patient tries you too much."

After I had taken his name and address, I asked him where he was employed. His eyes protruded and he stared without blinking, as he answered, "Didn't I tell you that no one wants me? I cannot get any work. America is at war, does Uncle Sam want me? No, I have been to all the recruiting stations here in New York, and all of them have refused me. I want to fight for my country's flag, but they won't give me a chance." He actually wept, and I could not refrain from crying too. His mind was affected, yes, but when he was calm, all he could think of was Uncle Sam, and how he wanted to fight for him. I was not acquainted with him a half hour when I understood easily enough why the United States could not use him. He demonstrated to Dr. Bates and to me very clearly that one can not have normal vision with a mental strain. I placed him ten feet from the test card and told him I wanted to test his vision. He answered, "I hope you will be able to improve my sight, because I think my nervousness will also improve."

He read a few lines of the card, but when he reached the fifty line he leaned forward in his chair, wrinkled his forehead and his eyes began to bulge. At that moment a small mirror from my purse, came in very handy. I held it before him, and the expression of his face changed immediately from strain and tension, to a look of amazement.

He waited for me to speak, and what I said affected him terribly. He covered his face with his hands and wept. I kept very quiet, but touched his shoulder lightly to reassure him. When he raised his head a few moments later, he said: "Maybe that is why they refused me. I guess they saw what you saw. No wonder they thought I was crazy." I feared more hysteria, so I said that if he would let me help him, no doubt the United States Army would be glad to admit him into the service. He left the office after his first visit, feeling very much encouraged. I could not improve his vision beyond the fifty line that day, and I decided not to test each eye separately. All I could record was 10/50 with both eyes.

One week later he came again. Apparently he had forgotten to practice anything he was told to do. His vision was still 10/50 with both eyes. I directed him to cover his one eye, and read the card with the other. His vision with each eye separately was the same, namely 10/50.

He told me that I had encouraged him so much that he tried again to enlist. I said, "You cannot expect to win out unless you take time to practice. This you must do all day long. When you tire of palming, keep your eyes closed and imagine something perfectly." While I was telling him all this, he had his eyes covered with his hands, and was moving his body from side to side, very slowly. What he did next certainly frightened me at first.

While his eyes were still covered, he asked me in a loud voice, "Do you mind if I sing 'America' while I am reading the card?"

I answered, "No, but perhaps the other patients might object. Just wait a moment and I will ask the Doctor."

Dr. Bates said if singing was his way of relaxing, by all means let him sing. That was all that was necessary. This poor fellow sang every word without a mistake. After each verse he would stop long enough to read the card. After the first verse he read two more lines 10/30. When he finished the hymn, he also finished reading the whole card without a mistake, 10/10. He blinked his eyes as he moved his body from side to side, and there came a great change in the expression of his face. I directed him to sing "America" when he practiced reading the test card at home every day. He left us in a very happy mood, and promised to practice as he was told.

We did not hear from him for a whole year. One day there came a letter from him, written in Bellevue Hospital, but mailed by a friend outside. He stated in his letter that he was all right, although he was confined. He also explained why he was sent there. It seems that when he applied at a recruiting station for enlistment, they found his vision imperfect. When he insisted that if they would only let him sing "America," his vision would at once become normal, the officers of the recruiting station considered this statement so absurd that they believed he must be crazy.

He was sent to the insane ward of Bellevue Hospital, where he was promptly admitted. While there, he wrote a play of three acts, all about the doctors, the nurses and patients. It was well written, and after he had persuaded some of the doctors to read it, they recommended his discharge.

He called to see us, and I found his vision was normal, 10/10.

His mental strain was relieved and did not return except temporarily, when he became excited and talked rapidly.

## **A Teacher's Experiment**

**By EDITH WOOD, Allendale, N. J.**

(This is a fine example of the results that can be obtained by teachers, parents and others, who have charge of children.)

IN September, while testing the eyes of my pupils, I came across Stephen Bodnar, a boy of ten, who was apparently blind in his right eye. In testing him, I brought him so close that his nose almost touched the test card, and still he said he could see nothing. I concluded there was nothing to be done. Some days later the pupils were lined in the yard, when an idea came to me. I called Stephen to one side so that we would be out from the shadow of the building. I covered his left eye with his cap, and turned his face directly toward the sun. Then I asked if he saw anything. He said, "No, it is all yellow." Next I passed my hand back and forth so that the shadow would pass over his eye. He said, "It gets light and dark." I knew then that there was sight there, so I arranged with Stephen to come to my room at one o'clock the next day.

I fixed a shield for his good eye, and when he came next day, after adjusting the shield, I took him to the window and asked him what he could see out there. He replied, "Nothing." Next I took a manila card four by seven inches. Printed on it were the figures, 6A. I had not planned to use the printing on the card. I merely passed it back and forth so that the shadow passed over his eye. In swinging the card I began close to his face, and gradually increased the distance, requesting him to let me know when he no longer saw the shadow.

When I got about two feet away from his face, he said he could not see the shadow any more. When I held the card at four feet,

he said, "I can see you. You have on a dark dress, and it has light spots on it." I immediately asked him to look out of the window, and he saw the boys and girls moving about. He could also see houses and a tree.

The next day at one o'clock he came again, and we repeated the work of the day before. After a few minutes he said, "There are letters on that card." I held the card still, and asked him if he could tell me the letters. He said there was a 6 and an A, but he could not tell the smaller letter, although he could see it was there. I put the card down, and asked him to look at me, and tell me what he could see. I had a gold watch, suspended from my neck by a black ribbon. He said, "You have a ribbon round your neck" I closed one eye and left the other open, and he told me what I had done. While I was fixing his attention on my face, with my left hand I brought my watch out. He said, "I can see your watch." I said, "Be careful, Stephen, or I'll fool you. Isn't that a large yellow button?" "No, it's a watch, for I see a ring, and a ribbon fastened to it," he answered.

Next he looked out of the window, and he could tell what the children were doing and how many windows there were in the houses. I told him about palming and the long swing, and asked him to do them morning and night, which he said he would do. I remember that he astonished me so with what he could do, that I thought he must be peeking with the other eye. I tried to prevent him from turning his head, but he would do it, so I got behind him and held his head. He read just the same as before.

I have seen very little of Stephen of late. When I last saw him he could read the whole test-card at eighteen feet, and he could read from a book held at the normal reading distance.

Stephen's progress at the start was so rapid, that it astonished me. After about one week's work with the shadow, I dropped that and confined the work to the test card and the book.

Had any one told me this story, I'm free to say that I would have been skeptical.

## Suggestions to Patients

By EMILY C. LIERMAN

**+ WHILE sitting do not look up without raising your chin. Always turn your head in the direction that you look. Blink often.**

**+ Do not make an effort to see things more clearly. If you let your eyes alone things will clear up by themselves.**

**+ Do not look at anything longer than a fraction of a second without shifting.**

**+ While reading do not think about your eyes but let your mind and imagination rule.**

**+ When you are conscious of your eyes while looking at objects at any time, it causes discomfort and lessens your vision.**

**+ It is very important that you learn how to imagine stationary objects are moving without moving your head or moving your body.** Stationary objects move when the eyes shift without moving the head/body, but moving the head and body with the eyes, in the direction the eyes are moving increases the ability to see the movement and moving the head, body with the eyes improves central fixation, eye movement, relaxation and movement of the neck, head, body, eye muscles.

**+ Palming is a help to you, and I suggest that you palm for a few minutes many times during the day, at least ten times. At night just before retiring it is well to palm for half an hour or longer.**

## New Year Fairies

By GEORGE GUILD

A CERTAIN man had much money. One day he gave forty million dollars to charity, and had a lot left. He invited me to spend an evening at his home. He asked me if I would like to learn how he made his money. I answered, "No."

"What would you like to talk about?" was his next question.

I replied, "Although you seem to be well advanced in years, your hair is not gray and your eyes seem good, because I notice that you are able to read without glasses. How have you been able to preserve your eyesight all those years?"

He smiled and answered, "I do not know unless it was due to the influence of the New Year Fairies." He stopped and waited for me to say something.

All I said was: "Tell me about it."

With his eyes partly closed, I can see him now, smoking his cigar slowly, and letting his mind drift away from me and his surroundings to a time long ago when he was a poor boy living on a farm. He told me that he had many brothers and sisters, all of them now dead. Christmas, one year, had been a very sorry affair. They had very little to eat, and their poverty was extreme.

New Year's Eve, as he sat by the open fire, a small boy of ten, he felt very hungry, very despondent, and very unhappy. He watched the flames of the burning wood, watched them grow larger, grow smaller, change their color, and, as he watched, a fairy appeared in the light. She had the most beautiful eyes that he had ever seen. They were so bright, clear, full of sympathy and love, that he could not look away from them. She seemed to read his mind, and spoke encouraging words to him, which made him feel better. Then another fairy, all dressed in blue, a very beautiful blue, waved her hands to him, threw him a kiss and started to dance. While she was dancing, other fairies came out of the dark and danced with her. It seemed to him that wherever there was a spot of light, there was a fairy, many fairies, all of them with the same sympathetic, loving, blue eyes of the first fairy.

The memory of these eyes has never been lost. He said that he could see them now just as clearly as he did in the long ago. The memory of these eyes brought with it a wonderful feeling of rest, relaxation, and comfort. It seemed to him that those fairies brought a blessing which had helped him to accomplish many things which other people believed were impossible.

After he went to bed in the dark it seemed that he could still see the burning fire, and all those fairies with their sympathetic and loving eyes. When he awoke next morning his attitude of mind was entirely different. He ran to each member of the family, his father, his mother, each sister and brother, threw his arms around them and wished them all a Happy New Year. He tried to dance

as he had seen the fairies dance, he tried to smile as he had seen them smile; he tried to be as sympathetic and as kind to everybody as the fairies had been to him. He was all eagerness to be busy. Formerly he had shirked what little work was expected from him, but now he had an uncontrollable desire get busy, to do things. He had no feeling of fatigue no matter how hard he worked, or how much he accomplished. His mother was amazed to have him fly around the kitchen, and to help her in as many ways as he possibly could. He brought in more wood for the stove than could be used in a week. He ran to the barn and started in cleaning house. It was the first time in his life that he felt a desire to do something to help the horses, the cows, and other animals. He got busy with a few tools and fixed up the chicken-coop, stopped all the cracks so that the cold air would not blow on the chickens, and all the time he was thinking of those eyes of the New Year Fairies, because the memory of their love did him so much good.

He felt a desire to go to school, and tramped through the deep snow two miles to get there. The teacher was surprised to see him and asked him what he desired.

"I want to go to school. I want to learn things. I want to be a big man. I want to make people happy."

The teacher smiled, gave him a desk, some paper, a pencil, and a few pages of a primer, and told him to copy as much of it as he possibly could. He used up a great deal of paper, and before school was out he had done something very wonderful, because he had copied all the pages that had been given him.

He told me that his health was always good, and as far as his eyes were concerned, he never gave them a thought. He knew that he could see well, but he was not conscious that he had eyes most of the time. When he was forty-five he had an attack of the grippe, from which he soon recovered, but when he tried to read the newspaper, he was very much alarmed to discover that his sight was very poor. He at once consulted an eye specialist, who told him that he needed glasses because all persons in middle life, past the age of forty, needed glasses. He had some business to attend to which occupied his time for a few days. During that time he tried to rest his eyes by not looking at the newspaper. After avoiding any use of his eyes for reading for four days, they felt quite comfortable. Later he picked up a newspaper, and was surprised to find that he could read it for a short time. When his eyes tired, he rested them, and he discovered that by reading the paper and alternately resting his eyes, his vision improved to the normal. At subsequent periods in his career he had similar attacks of being unable to read, which were always relieved by rest. He felt that as long as he could improve his sight by resting the eyes, it would be perfectly safe for him not to wear glasses.

"It may sound very queer to you," he said, "but I find that I can obtain perfect relief immediately when I remember the sympathy and love in the eyes of those New Year Fairies."

## Report of the League Meeting

By MISS MAY SECOR, Secretary

A REGULAR meeting of the Better Eyesight League was held at 383 Madison Avenue, on the evening of December ninth. Miss Kathleen Hurty, president, presided.

Miss Hurty announced that the annual election of officers will be held at the January meeting. The nominating committee was appointed as follows: Mrs. Warring (chairman), Miss Agnes Herrington, and Miss Mabel Young.

Miss Hurty gave an exposition of the Bates Method. Miss Agnes Herrington, a teacher in Erasmus Hall High School of Brooklyn, told of the great benefit she had derived from the use of this method. Miss Herrington wore glasses for ten years; she has now discarded them, with the exception of occasional use to read very small figures. Dr. Bates advised those who experience difficulty in reading small print to relax by means of palming and swinging; this will relieve eyestrain, and the small print will become legible. Miss Herrington found the following most helpful: **sun treatment, blinking, and imagining a white cloud upon which is placed a black "o" having a period on either side.**

Mr. George Weiss reported several cases which are under treatment at Erasmus Hall High School. These cases are all showing marked improvement. One case has been cured of insomnia as a result of relief from eyestrain. Mr. Norman Bernat, a member of Miss Hurty's eye group at Erasmus Hall, reported that by means of the Bates Method he has secured normal vision. For seven years he had used artificial lenses—one set for general use, one for reading, and one for "the sun." Mr. Bernat demonstrated the long swing in an unusually pleasing and relaxed manner.

Dr. Bates reported a case in which the patient was unable to see things moving. The Doctor requested the patient to look at the upper left hand corner of the small square of the Snellen card, to sway, and to hold the corner stationary. The patient followed instructions, and a severe headache resulted; after this experience, however, she was able to see things moving. Dr. Bates explained that it is sometimes advisable to teach a patient how to use his eyes in the wrong way, in order to effect a cure. Another case had occasional attacks of complete blindness. **Dr. Bates taught this man how to consciously produce complete blindness; the lesson was a difficult one. The result, however, was complete relief from attacks of blindness. After his cure the man served over-seas; when he returned to New York his vision was still normal.**

Dr. Bates treated one case which had been diagnosed by neurologists as insanity. This man had double vision at times, and frequently saw imaginary figures dancing on the top of tall buildings; it sometimes appeared to him, also, that men approaching him took off their heads, and carried them under their arms. In this case a correction of the visual defects removed all apparitions, and the man was recognized as normal. Dr. Bates spoke also of a little girl who attained very high visual acuity by means of central fixation, seeing best a part of each letter. **The Doctor stated that floating specks are the result of imperfect imagination, and are a sign of strain.** At the close of Dr. Bates' discussion the meeting was adjourned.

Imagine a cloud with a small black o upon it with a period on the left and right sides of the o. Shift left and right on the o, one period to another and see, imagine the o swing in the opposite direction.

## Announcement

We are pleased to announce that Capt. C. S. Price, of London, England, will visit Dr. Bates around the latter part of January. He is planning to discuss with Dr. Bates the best methods which are employed for the cure of imperfect sight without glasses. The spread of Dr. Bates' method in England is largely due to Capt. Price's enthusiasm and success in helping others. There are now two clinics, and a Better Eyesight League in England, all reporting favorable results. We are hopeful that Capt. Price will attend the February meeting of the League.

## Questions and Answers

Q—What is the difference between the long and the short swing?

A—In the long swing, objects appear to move an inch or more. In the short swing, objects appear to move an inch or less.

Q—My hands become tired when I palm. Can I sit in a dark room, instead of palming? Can I cover my eyes with a dark cloth?

A—No. I have found this to be a strain.

Q—While palming is it necessary to close the eyes.

A—Yes.

Q—When I read and blink consciously, I lose my place.

A—This is caused by strain, which prevents one from remembering the location of letters.

Q—How long is it necessary to read the test card before obtaining benefit?

A—Some patients by palming, and resting their eyes, have obtained benefit in a few minutes.

### CATARACT NUMBER BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

February, 1925

#### The Baby Swing

YOUNG babies suffer very much from eyestrain. **The tension of the eye muscles is always associated with the tension of all the other muscles of the body.** Their restlessness can be explained by this tension. I was talking with an Italian mother in the clinic one day about restless children, and asked her why it was that her baby was always so quiet and comfortable when she came to the clinic, while many other babies at the same time were very restless and unhappy.

"Oh," she said, "I love my baby. I like to hold her in my arms and rock her until she smiles."

"Yes, I know," I said, "but that mother over there is rocking her baby in her arms, and the child is screaming its head off."

"Yes," exclaimed the Italian mother, "but see how she rocks it."

Then I noticed that the other mother threw the child from side to side in a horizontal direction with a rapid, jerky, irregular motion, and the more she jerked the child from side to side, the more restless did it become.

"Now, doctor," said the Italian mother, "you watch me."

I did watch her. Instead of throwing the child rapidly, irregularly, intermittently from side to side, she handled her baby as though it had much value in her eyes, and moved her not in straight lines from side to side, but continuously in slow, short, easy curves.

The Italian mother picked up the other mother's child, and soon quieted it by the same swing.

I learned something that day.

### Cataract

By W. H. BATES, M.D.

CATARACT is a form of imperfect sight in which the lens of the eye becomes opaque. It usually begins after the age of fifty, and may progress in the course of a year or longer to complete blindness. In most cases perception of light can be demonstrated in all parts of the field. In many cases, cataract in one or both eyes is found at birth. There are also a smaller number of cataracts which appear after an injury to the eyes. Diabetes and other general diseases are believed to be a cause of cataract. As a rule cataract is progressive.

In 1895, a well-known ophthalmologist asked me, one of his assistants, to collect the histories of all cases of cataract which recovered without treatment. There were many such cases. It seemed to me that since recovery of cataract occurred without treatment, although the majority needed an operation for the removal of the lens before they were able to see; some form of treatment might help more of these cases. I sent some of my private patients to general practitioners who at that time by various methods did benefit these patients in quite a number of instances.

Not long afterwards I attended a meeting of the Ophthalmological Section of the American Medical Association, and listened to a paper on the treatment of cataract in which the writer declared that any doctor who claimed to cure cataract without an operation was a quack or something worse. I did not think he was right, and gave a talk on my experience, which produced something of a sensation.

More than forty years ago, when I was a student in a medical college, one of the professors gave a lecture on the eye. He had a number of nucleated eyeballs from the cow. He demonstrated that when the eyeball was squeezed with the aid of his fingers, an opacity or cataract of the lens at once appeared. I could see this more than twenty feet away. When the squeeze was relieved, the lens at once became apparently perfectly clear. I have repeated this experiment on the eyes of other animals without failure.

One day I was studying the eye of a patient with partial cataract. While the patient was talking of various things of no special consequence, I could see through several openings in the cataract, areas of a red reflex, which was evidence that the lens was not completely opaque. I asked the patient how much she could see, and while she told me the letters on the Snellen test card that she could read, the opacity of the lens was incomplete. She then made an unsuccessful effort to remember some of the smaller letters, when much to my surprise, the whole lens became opaque. I repeated the observation as follows:

I asked her: "Can you remember that you saw the big C?"

"Yes," she answered, and then at once the lens cleared in part, and I could see the red reflex through the open spaces.

Then I asked her: "Can you remember having seen any of the smaller letters on the bottom line?" I could see that she was making a considerable effort when the lens became completely opaque. I was so interested that I had a number of friends of mine

repeat the experiment, and they were just as much astonished as I was when they obtained the same result.

Strain in the mind = eye muscle tension = pressure on/in the eye, lens = cataract.

Relaxed mind, easy to remember a object clear = relaxed eye muscles = no pressure on eye, lens = cataract disappears, cured = vision clear.

So many patients are depressed, or become very unhappy, when they learn that they have cataract. The prospect of an operation, with its dangers and uncertainties, is too often a punishment. When an elderly patient with loss of vision is brought to me for treatment, the friends or relatives usually request me not to tell him that he may have cataract. For many years I followed this practice, gave the patient glasses, and deceived him as well as I knew how. I felt a great responsibility which I was always anxious to be rid of. I was ashamed of my cowardice. It was a great relief to have such patients consult some other physician. At the present time this has all been changed. I welcome cataract patients now, and rejoice in the fact that they have cataract because I am always able to improve the vision at the first visit, and ultimately cure them if they continue some months, or longer, under my supervision. Cataract is more readily cured than diseases of the optic nerve or retina. I believe that I am justified in telling the patients that the cause of the imperfect sight is due to cataract, because when they know what is wrong with them, they are more likely to continue to practice methods of treatment which are helpful.

The vision of every case of cataract always improves after palming, when the patient learns how to do it right. I have seen many serious cases obtain normal vision with the disappearance of the cataract, by practicing the palming and nothing else.

It was a shock to me to see a case of traumatic cataract recover with the aid of palming. **Cataract, occurring in patients with diabetes, has also disappeared without treatment or cure of the diabetes.**

Treatment which is a benefit to cataract has for its object relaxation of the eyes and mind.

The quickest cure of cataract is obtained by the memory or imagination of perfect sight. It can be demonstrated that when the patient remembers some letter as well with the eyes open as with the eyes closed, that the vision is improved, and when the memory is perfect with the eyes open, perfect vision is obtained at once and the cataract disappears. This startling fact has been ridiculed by people who did not test the matter properly. When the patient stares, concentrates, or makes an effort to see, the memory, imagination, the vision, always become worse. The patient and others can feel, with the tips of the fingers lightly touching the closed upper eyelid, that the eyeball becomes harder when imperfect sight is remembered or imagined. But when perfect sight is remembered or imagined, it can always be demonstrated that the eyeball becomes as soft as is the case in the normal eye. When the patient practices the swing successfully, or practices other methods which bring about relaxation of the muscles on the outside of the eyeball, it becomes soft, and the cataract is lessened.

After an operation for the removal of cataract, a thin membrane usually forms over the pupil of the eye, which impairs the vision. This membrane is called a secondary cataract. Sometimes another operation, a puncture through this membrane, is beneficial. In a recent case, a man, after the removal of the lens for congenital cataract, came to me for treatment. Without glasses his vision was 15/200; with convex 15.00 D. S., the vision was improved to 15/70+.

The patient hesitated about taking treatment at this time because he had heard that I always removed the glasses. He felt that on account of his work, he had better defer the treatment until such time as it was convenient to go without his glasses. I asked him if he would go without his glasses if I improved his vision so that he could see as well, or better, without them, as he was now able to see with them. He answered that he would do as I recommended. With the aid of palming, swinging, and perfect memory and imagination, the vision very promptly improved to 15/15.

## Stories from the Clinic

### No. 60. Two Cases of Cataract

By EMILY C. LIERMAN

SO many times I have been asked, "Is it really possible to cure cataract by Dr. Bates' Method?" I can prove that it is. In the March, 1920, number of "Better Eyesight," I wrote about a case of cataract under treatment at the Harlem Hospital Clinic. This case was a woman seventy-three years old who was determined to be cured without an operation. In October, 1916, she had visited another dispensary where an operation was advised. The doctors there told her however that she must wait until the Cataract was ripe before the operation could be performed. Later she heard about Dr. Bates curing cataract without an operation, and tried out the method as well as she could all by herself. In March, 1919, she visited Dr. Bates in his office, and he helped her.

This woman made her living by mending clothes in an orphanage, so we were glad to treat her in the Clinic where she did not have to pay. Three days a week she came, no matter how bad the weather was.

On her first visit she read the forty line at four feet from the test card, then her vision blurred. She knew just what to do, and I did not have to tell her to palm. Just once she peeped at me through her fingers and said, "I'll fool the other doctors yet. My eyes won't have any cataract if I keep this up." She had a way of smiling out loud, and she still has. Her disposition has not changed a bit in all the time I have known her.

Recently she came to the Clinic to see me. In the room were two school nurses, and a young man who were there to observe the cases under treatment. I was not so sure that my dear old lady had retained her improved vision, because I had not seen her for a year or more. I placed the test-card eight feet from her eyes and she read every letter correctly up to the fifteen line without the aid of palming. At times she read 10/10 after resting her eyes with the aid of palming and blinking.

The test I made this day was the best yet, because she read a strange card which she had never seen before. Then I placed her in the sun and gave her the doctors fine print card, which she held six inches from her eyes. She looked at me in a funny way, and said, "Oh, I can read that easily." Then she proceeded to read the diamond type to the amazement of the others in the room.

Some day I am afraid the little lady will get into trouble. Whenever she sees a child in the street wearing glasses, she gets very much excited.

Recently she stopped two women with a child on the street and found fault with them because the little girl, three years of age, was wearing glasses. "Why don't you take that child to my doctor; he can cure her without glasses!"

Those who know our dear old lady can very well understand her good intentions, but how about the mother and friend of this little girl? They must have thought at first that she was of unsound mind. The women treated her kindly and accepted the "Better Eyesight Magazine" which she offered them.

We had another case of cataract under treatment at the Clinic, a man sixty-three years old. He had to have someone to lead him when he first came, which was less than a year ago. After his fourth visit to the Clinic he was able to travel by himself.

When Dr. Bates examined him with the retinoscope on the first day, he could see no red reflex in either eye. I gave him a test card which he held very close to his eyes, and after he had palmed for a little while and imagined he saw the test card moving opposite to the movement of his body, he could make out the big C of the card at two inches from his eyes, but it looked very much blurred to him. Before he left the Clinic that day he became able to read several lines of the test card, and the letters cleared up which, of course, gave him a great deal of encouragement. What helped him so quickly was that he was quite sure we could improve his sight. He did exactly as he was told. Keeping up that steady swing of his body while standing, slow and easy, without any effort, stopped the staring, or prevented it. Palming and imagining his body was moving were a rest and relaxation to him also.

After he had been coming for a month or more, he became able to read all the letters of the test card, as he held the card very close to his eyes. Three months later he was able to read the large letters of the card two feet away, and the ten-line letters of the bottom line at three inches from his eyes. Always when he came, which was every Saturday morning, he had something encouraging to tell us about his eyes. The signs in the sub-way on his way from Brooklyn became more clear and distinct. He was able to dodge people in a crowd. At the present time, even people with normal vision have to be mighty careful to avoid injury both in the street and in the subway.

It is now about ten months since this patient first came for treatment, and on his last visit he read very fine print at three inches from his eyes, and saw the fifty-line letters more than a foot away. His vision improves by practicing with print much finer than diamond type, and his jolly disposition is also a great help.

It is a great relief to be able to say to a Clinic patient when he first comes to us: "You are welcome here for treatment, no matter where you live." At the Harlem Hospital Clinic, the authorities there turned away many poor souls who needed treatment of their eyes. Each district has a free hospital, and those who lived in another district were not admitted. While it was pitiful, it had to be so, because we could not take care of them all.

Here in our office also, we have to limit the number of patients treated in the Clinic, so we can only take care of patients who have no source of income, or who are sent to us by physicians.

## Strain

By EMILY A. MEDER

WE are often awed by the almost uncanny wisdom of the philosophers and teachers who lived centuries ago. After extensive experiments and research work, our scientists discovered certain properties in a drug, which proved invaluable during the War. It was later found out that this property had been used as an every-day remedy in Japan for centuries. **It is well known that India possesses the secret of cures for various diseases, which our scientists would be glad to know of.**

Dr. Bates has made the important discovery that all cases of defective sight are caused by strain, tension or rigidity of the eye and mind. There are a great many people who refuse to accept this fact, although their imperfect sight, and perhaps other troubles are due to this cause.

Read what one Chinese Sage wrote about strain many, many years ago:

"In love or in hate, rigidity is final; in art fatal. Elasticity means life in the plants and flowers and trees, and in the wings of a bird, as in the mind. When the sap goes from the branches, they become rigid, and the storms break them down. When the artist's mind closes against the new ideas that are the mind's strength, as the sap is the trees, the brain becomes rigid, and arid, and neither philosophy, poetry nor painting can be produced thereby. "Rigidity and death are synonymous."

The eyes have perfect sight when they are relaxed. It is not difficult; when there is an absence of strain, the eyes do nothing. They don't squint, or stare or try to see.

When the eyes are relaxed, the body is relaxed, strain disappears, and the truth of Dr. Bates' discovery is proven.

Remember—Rigidity, strain and death are synonymous. Be relaxed!

## Clinic Reports from London

We have heard from several of our English correspondents praising the work done by the "Better Eyesight League of Great Britain and Ireland." We are pleased to publish a few of Mr. Price's reports. Notice that all cases are accepted, including those with little perception of light, which have to be led into the office. A history of the progress of these severe cases proves the usefulness and need of this work.

### A MAN BLIND IN ONE EYE FOR MANY YEARS

THIS is the case of a man who has endeared himself to all of us. He is a match seller in the gutter of one of our streets and partly because of his curly hair and partly because of his sunny smile (he is an Irishman) we have christened him Curly. There are occasions when his cheeriness is of great assistance to the other patients.

His vision when first tested was 10/60 with the right eye and nothing whatever with the left. He had no perception of light in the left and said that he had not had for many years, and was told at the hospital that it was quite gone and nothing could be done.

His vision has improved to 10/50 and the left eye is much better and has quite a good perception of light. His near sight has improved more than his distant.

(We are in hopes that Capt. Price can send us a further report of Curly's progress.)

### BLIND FOR FIVE YEARS

(This case should encourage those who have only slight perception of light.)

A few weeks ago there was lead into the Clinic a man of 65 who told us he had been blind for five years and the doctors at the hospital had told him nothing more could be done for him, as his case was hopeless.

On testing his sight we found the right vision 3/80 and the left vision only just perception of light.

He was eager to know if we thought he could be helped and listened attentively while he was being told how to palm and how to strengthen his eyes by splashing them with cold water. He started right away palming and was left to amuse himself in this way, while other patients were attended to, and afterwards he said his eyes felt rested and much easier. He was asked what he was to do at home during the week to see if he had remembered the directions given to him, and then went home in a very hopeful frame of mind.

The following week he came along and looked rather more cheerful and was very excited to tell us that he thought he could see a little with the blind eye. Both eyes were tested, the right one was now 3/60, and with the blind eye he could see the big C, the 200 line when the Chart was held close.

Two weeks later we held the Clinic in another room and we were amazed to see him walk boldly in alone. He was looking much better and very proud of himself. He had been under the doctor's care for the last two or three months as he was generally run down, and this week he was delighted to tell us that he had caught his doctor napping. His doctor had greeted him one morning by saying how much better his eyes were looking, how much brighter and more alive. "Yes, because I am having treatment for them," said our friend. He told the doctor of the treatment, whose reply was that it was rubbish and could not possibly do any good. "Well, you said yourself how much better they were looking, and they must look very different for you to notice them and remark on them, and besides I can see more than I did."

He continues to be very much in earnest and is now able to see 3/30 with the right eye, and can read the 40 line quite easily close up to the other eye which previously had only perception of light.

### A MAN WHO HAS WORN GLASSES FOR 60 YEARS

This man without his glasses was very helpless. He had no vision at all with the right eye, just perception of light, but very slight. The left eye was such that he could read with difficulty the 60 line at 6 inches. In three weeks the vision with both eyes was improved, so that at 6 inches he could read the 20 line comfortably and the 15 line with difficulty. The right eye is better but the improvement is not so marked as that of the left. It is a great joy to help this man, he is so grateful for the smallest thing that one does, and his childlike faith and obedience is something rarely seen. The reason he has made so much progress in so short a time is due to the fact that he cooperates willingly and with pleasure and is really interested in getting his sight.

One notices that on the whole people with slightly imperfect sight are not sufficiently interested in getting their sight normal to take much trouble. If it could be done for them they would not mind; but they do not like to bring it about themselves. The continuous relaxation practiced by those with imperfect sight is a joy to see and they are well paid for it.

### The Elephant and the Fairies

By GEORGE GUILD

IT is a fact that few of us realize that we have never seen a fairy wearing glasses. Why shouldn't they wear glasses? Little boys and girls wear glasses. Little boys and girls like fairies, yet it is unheard of for fairies to imitate what other people do, and wear those dreadful goggles which spoil the eyes and faces of beautiful young children. Many a fairy has whispered in the ears of children that glasses are bad. Many a fairy has whispered into the ears of a mother that glasses were an injury to the eyes, with the result that mothers who enjoy the society of their children are troubled about the glasses.

One evening after everybody had gone to bed, the father of a family sat in his chair dozing, after he had read the evening paper. Many fairies came and whispered in his ears that glasses were bad for his children. He tried to argue the matter with them.

"Why shouldn't they wear glasses? The doctor says it does them good. They cost a lot of money, and my children are all the time breaking them. But if it does them good, why shouldn't they wear them?"

The fairies remonstrated with him and told him that he could not see with his eyes, he could not see with his mind, and that he was just as blind as the five men were who tried to describe an elephant which they had never seen.

"Well, tell me all about it," said he.

So one of the fairies perched herself on his right shoulder, and told him the story which illustrated how wrong some people can be.

Once upon a time many centuries ago, an elephant came to a small village where no person had ever seen such a creature before. Five blind men were coaxed with some flattery to give their opinion of the elephant.

One grasped the tail and declared: "The elephant is very much like a snake." The roar of laughter from the spectators upset him very much.

The second blind man leaned against the side of the elephant and said: "The elephant is very much like a high wall." The applause of the mob was tremendous.

The third handled one of the elephant's legs. "Yes," he said, "The elephant is very much like a pillar." The applause which followed bothered him.

The fourth grasped one of the elephant's ears, and very solemnly asserted: "The elephant is similar to a fan." More applause and laughter greeted this opinion which also disturbed the blind man.

The fifth felt of the sharp pointed tusks, and said: "The elephant is very much like a spear." As an encore to the applause, he corrected himself and announced: "The elephant is like two spears."

The five blind men gathered together. The vigorous arguments of each blind man to prove that he was right and that all the others were wrong, amused the populace for some hours.

The world is full of blind people who have eyes and minds which do not see. The world is full of Good Fairies who teach us how to see with our eyes and minds.

The next morning the father told his wife all about his experience with the fairies, and when the children appeared for breakfast wearing their large rimmed spectacles, he saw how their eyes and faces were injured by them. His wife saw the same thing, and they both exclaimed in one breath: "Take off those horrid glasses, and never wear them again."

Then the little girl took off her glasses and dropped them in the waste-basket with a smile. The little boy dropped his on the floor and, with the heel of his heavy shoe, he smashed them into little bits, and laughed.

The father was astonished, and asked: "Why did you do that?"

The little boy laughed loudly, and cried: "Because I have got the best of the horrid things. They never did me any good. They hurt my eyes and kept me off the baseball team. I cannot tell you how glad I am to be rid of them."

The little girl also was smiling, and they soon were all smiling, and they have been smiling pretty much all the time ever since.

## Report of the League Meeting

By DOROTHY MAITLAND

THE annual business meeting of the Better Eyesight League was held Tuesday evening, January 13th, at 383 Madison Avenue. We noted with regret the absence of the secretary, Miss Secor, who was ill. Miss Hurty conducted the meeting.

The treasurer's yearly report was made and accepted.

For the benefit of the visitors, Miss Hurty briefly outlined the work of the League and the part each loyal member takes in it. This is to improve his own vision and help others to improve theirs. The work with children was emphasized as being the most essential point in the League's work. Those in charge of children were asked to cooperate with the League in order to reach those children whose defective vision can be corrected at the start.

The nominating committee submitted the following list of officers for the ensuing year. The acting secretary cast a unanimous vote in their favor. The new officers are:

Miss May Secor, President.  
Mr. N. A. Weiss, Vice-President.  
Miss Mabel Young, Secretary.  
Mrs. Wm. R. Marsden, Treasurer.

In view of Miss Secor's absence, Miss Hurty continued as chairman for the evening.

Miss Hurty cited a case of a boy in her class last year who suffered with severe headaches. He received no special treatment but worked out suggestions with good results. He now claims Miss Hurty cured his eyes and relieved his headaches entirely.

Dr. Bates gave us an interesting talk on cataracts. **He explained that although all imperfect sight is due to strain, each defect is caused by a different kind of strain.** When one has cataracts the eyeballs become hard. Relaxation through swinging, a perfect memory or a perfect imagination softens the eyeball and the cataract disappears. Dr. Bates claims that nearly all cases of cataract are materially benefited at the first visit. Babies with cataracts have been cured when the mothers swayed them in their arms.

(Thumb/finger movement)

Have you learned to swing by means of your thumb? If not, try it now. Place your thumb and forefinger together and rub them lightly in a circular movement. When done correctly you will feel your whole body move and everything about you will seem to move. You know the value of this form of relaxation.

An instance was cited of a movie director who carried a large diamond in his vest pocket and unless he kept moving that diamond between his thumb and forefinger he could not direct his cast. The gentleman who related the case realized the significance of it as soon as the thumb movement was explained to him, and he was very glad to tell us about it.

Perfect sight is natural and a normal condition, and those who have bad vision sometimes instinctively do those things which help them and improve their sight.

The meetings are proving so helpful and officers so enthusiastic that we extend a warm invitation to all those who are interested in this work.

### Thumb, Finger Movement

Place the top of the thumb on the top of the pointer finger and move the thumb on the finger in a small circular movement: Counter-clockwise, clockwise, counter-clockwise...

The finger is stationary.

Next: Move the thumb left and right, up and down, diagonally on the finger tip.

Practice with left and right hands. (The finger can be moved on the thumb with the thumb stationary if preferred.)

This is a form of the swing movement, you can see and feel oppositional movement as the thumb moves on/against the stationary finger. The finger and thumb appear to move opposite each other.

This activates relaxation, eye shifting, movement of the body, left and right brain hemisphere activation/integration, clear vision.

A famous successful movie director kept a large diamond in his pocket and kept moving the diamond between his thumb and forefinger when directing.

## Helpful Hints from Correspondents

These are extracts from letters received from book readers and others. They might suggest new ways of improving your vision.

"I AM proud of my ability to eliminate headaches, fatigue and even nausea resulting from eyestrain. I formerly retired to my room when one of my severe headaches came on, and required the entire household to be absolutely quiet. Now, if my head or eyes pain, I go to my room, palm for a few minutes, swing the card, and feel rested. The headaches usually disappear when I am relaxed.

Another discovery! The headaches only come when I do something wrong. The last one was caused by late shopping, rushing to put the house in order, and cooking the whole dinner myself. When I slowly did the long swing (with the broom in one hand and a duster in the other), I grew calm enough to greet my guests pleasantly."

"I was shocked to discover that I was a starrer. I knew that Dr. Bates advocated blinking to prevent the stare, and thought that I blinked and shifted constantly. Upon watching myself, however, I found that I only blinked when I remembered to do it consciously. I have made it a rule now to blink my eyes at the end of each line. This compulsory rule is becoming easier, and I believe that it will become a good habit real soon."

### Questions and Answers

Q—What is most helpful when one is dreadfully nearsighted and finds it almost impossible to see without glasses?

A—Practice palming as frequently as possible every day. Keeping the eyes closed whenever convenient for five minutes ten times a day is also helpful.

Q—I notice that my squint eye does straighten after palming, but reverts when I stop. How can I tell when and how I strain?

A—Avoid staring after palming and blink all the time. You can demonstrate that staring is a strain by consciously doing it for a few seconds.

Q—If glasses are harmful, how do you account for the benefit the wearer receives; also relief from headaches?

A—(a) Eye glasses are harmful because the benefit received is not permanent. (b) The mental effect of glasses helps some people, but the headaches are not relieved permanently and the vision is usually made worse.

Q—Why is fine print beneficial?

A—Fine print is beneficial because it cannot be read by a strain or effort. The eyes must be relaxed.

Fine print activates perfect central fixation with shifting.

Q—How can I correct the vision of my three-year-old son, who won't palm and doesn't understand it? He is far-sighted.

A—Make a test card with black letters on white paper. The letters to be composed of E's pointing in various directions. These are to be graduated in size, from about 3½ inches to a quarter of an inch. Have the child read them from 10 to 20 feet away. Have him blink constantly while telling in which direction the E's are pointing.

Pothooks, Tumbling, Inverted E Eyechart

### BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

March, 1925

#### The Elliptical Swing

THE normal eye when it has normal sight is always able to imagine stationary objects to be moving from side to side about one quarter of an inch, slowly and without effort. This is called the swing. In order that the swing may be continuous, the movement of the head and eyes should be in the orbit of an ellipse, or in an elongated circular direction.

A patient, aged seventy-seven, with beginning cataract in both eyes had a vision of 3/200 when she looked to one side of the card. When she looked directly at the card or the letters, she complained that she could not see them so well, or at all. She was recommended to practice swaying the body from side to side. Every time she moved to the right or to the left, she stopped at the end of the movement and stared, and that prevented relaxation. With the help of the Elliptical Swing, she obtained at once very marked benefit. Her vision was improved almost immediately when she looked directly at the letters, and her vision became worse when she looked to one side of the card.

A young man, aged sixteen, was treated for progressive myopia for a year or longer. His vision improved for a time, then improvement stopped. Some months later his vision had not become permanently improved. Palming and swinging no longer helped him. I noticed that when he would move his head from side to side, he stopped at the end of the swing and stared. When he practiced the Elliptical Swing, his head and eyes moved continuously, and the staring was prevented. At once there was a decided improvement in his vision, and this improvement continued without any relapse.

Modern teachers use the infinity swing, figure eight.

Shift left and right on the house and see it move 'swing' in the opposite direction. Move the head with the eyes, in the same direction.

Elliptical Swing

Modern Figure Eight, Infinity Swing is a improved version of the Elliptical Swing. Trace along the eight with the eyes: Move up the center and to the left first. Head moves with the eyes, same direction. Notice the neck moves, relaxes.

## Limits of Vision

By W. H. BATES, M.D.

THE text books on the eye which have been published during the past hundred years or more, state that normal vision is limited by the anatomical structure of the retina. They describe the size of the center of sight to be so small that it is not possible for the normal eye to see the line marked 20 on the Snellen test card at a greater distance than twenty or thirty feet.

It is well-known that persons can read smaller letters, or letters one-half that size, at the same distance. It can be demonstrated that the small letter O with a white center, which can be imagined to be whiter than the margin of the card, can be seen perfectly at any distance when one can imagine the white center perfectly white. Some patients become able to imagine such a letter perfectly at thirty feet, a vision of 30/10. Others can imagine the small letter perfectly at a distance of forty feet, 40/10, at fifty feet, 50/10. The perfect imagination of the letter O, or of other objects is always associated with perfect sight of other letters or objects not known.

**FIELD.** In many cases of imperfect sight not only is central vision lowered, but there is also a loss of the ability to see objects off to one side. Perfect imagination is a cure for an imperfect field. In some cases of imperfect sight not only may the whole field be limited in its extent, but also small areas of the field may be absent or modified. In some cases of disease of the optic nerve or of the center of sight, the patient's vision looking straight ahead may be imperfect or absent. Some cases of no perception of light in any part of the field have been observed in which the imagination of perfect sight has been followed by a prompt recovery. It is difficult to understand in some cases of destruction of the center of sight of the retina, with total or partial loss of vision, how the use of a perfect imagination has been followed by a permanent cure.

**NIGHT BLINDNESS.** Some persons with imperfect sight see better in a bright light than they do in a dim light, and some cases are so marked that they have been described as cases of night blindness. These cases are cured at first temporarily, later more continuously by the perfect imagination of the letter O or some other object as well in a dim light as in a bright light.

**DAY BLINDNESS** also occurs quite frequently. Some patients in a good light, with correcting glasses, may read only 20/100, but after the light is dimmed, the vision may become 20/10 without glasses. These cases are quite readily cured by the intelligent use of sun-gazing. When the patient becomes able to imagine letters in a bright light as well as in a dim light, the vision becomes normal.

**COLOR BLINDNESS.** All persons with imperfect sight have an imperfect perception of colors. They may see large letters blacker than small letters, or the white spaces in the neighborhood of large letters whiter than the white spaces of small letters. Some patients will describe the color of the large letter C of the 200 line as blood-red, or they may see the large or small letters a shade of blue or yellow, or purple, or any color. The perfect imagination of one letter or other object is a cure for these cases of color blindness. Even cases of color blindness associated with diseases of the retina or of the optic nerve are cured by the intelligent use of the imagination. Persons born with color blindness are also cured in the same way.

**SIZE.** The size of letters of the Snellen test card or of other objects depends entirely upon the imagination. If the imagination is perfect, one may imagine the size of known or unknown letters at the near point or at the distance correctly. If the imagination is imperfect, the size of letters or other objects will be imagined incorrectly. It is interesting to observe that artists who are familiar with the sizes of things which they draw, very seldom present a perfect drawing of one object. A portrait painted by one painter may look entirely different from a portrait of the same person by some other artist. Most artists fail to make an accurate drawing of various objects, because of the variation in their imaginations from day to day, or under different conditions of light. A drawing may be made of a plaster cast which may appear all right when first completed, but may contain many faults when studied by the same artist at other times, in other places, or under a different light. The setting sun usually appears to be much larger than it was when overhead. This is an illusion or an imperfect imagination. Some scientists have demonstrated with the aid of a photographic camera, that the sun is always of the same size when viewed overhead as it is when viewed on the horizon.

**TREATMENT.** It can be demonstrated that we see not the image focused upon the retina, but our interpretation or our imagination of this image. Imagination, when used properly, is the most satisfactory, most accurate, most helpful method that we know to obtain

perfect sight. At can be demonstrated that if our imagination for something is as good at twenty feet, forty feet, sixty feet, or further, as it is at a nearer point where we see it perfectly, our vision is just as good as our imagination. It can be demonstrated that it is only possible to remember perfectly what has been seen perfectly. We can only imagine perfectly what we can remember perfectly. We can only see perfectly what we can imagine perfectly. These facts can be considered to be true because there are no exceptions. The difference between a theory and the truth is only a difference of fact. A theory is not destroyed by any exception, but one exception destroys the truth. The truth admits of no exception. The only reason we cannot see a star with the naked eye as well as with the telescope is our lack of imagination. To improve the imagination it is first necessary to improve the memory; to improve the memory it is first necessary to improve the sight; to improve the sight it is first necessary to improve the imagination.

**HALOS.** For example, persons with good sight appear to see the white spaces between the lines of fine print to be whiter than the margin of the page. It can be demonstrated that this is an illusion. We do not see illusions; we only imagine them. When the white spaces between the lines appear whiter than the margin of the page, we call these white spaces halos. Most of us believe we see them, and it is very difficult for many people to realize that the halos are not seen, but only imagined. The halos might be called the connecting link between imagination and sight. To see the halos is to improve the imagination, and the vision for the letters is also improved. One can improve the vision for reading not by looking at the letters, but by improving the imagination of the halos. To look at the letters very soon brings on a strain, with imperfect sight. To look at the white spaces and to improve their whiteness, is a benefit to the imagination and to the vision. One cannot read fine print at all unless the halos are imagined. By practice one becomes able to imagine or to see the halos more perfectly—the better the imagination, the better the sight. Vision is also improved by shifting on the letters, moving the eyes along the print, blinking, relaxation, (no effort, no squinting) even if the print is unclear. Reading through the center of the words, sentences also improves the vision by activating central fixation.

## Stories from the Clinic

### No. 61: Two Blind Girls

By EMILY C. LIERMAN

ROSALIE

ONE day a doctor asked me if I would help two blind girls that he knew. I said I would be glad to see them, and help them if I could. One was Eleanor, aged sixteen, and the other, Rosalie, aged seventeen.

Dr. Bates examined their eyes with the retinoscope, and this is what he found. Eleanor had myopia in the right eye and atrophy of the optic nerve in the left eye. This is very seldom or never cured. There was a good deal of inflammation inside of both eyes.

Rosalie had retinitis pigmentosa in both eyes, and could not count fingers in an ordinary light. This is also a very serious defect. In a very strong light she could at times count fingers if held close to her eyes. Rosalie would cure anyone of the blues because she carried a smile that was continuous. She had black curly hair and olive skin. I held a conversation with her for a few minutes purposely in order to get acquainted, and also to watch her eyes while she was talking. The first thing that I noticed was that she stared and kept both eyes open all the while she was talking. I did not see her blink at all. She had a habit of talking rapidly, and I noticed that she moved her eyes from side to side about at the same rate that she spoke. This is called nystagmus. I held the Pot Hooks card with the letter E of different sizes, pointing in various directions, close to her eyes, and she said I was holding something white before her.

I asked, "Do you see anything else on the card?"

"No," she answered.

Then I placed the palms of her hands over her closed eyelids and told her that this was palming. I told her that it was necessary to remember agreeable things, and she said she could easily remember her music. I could well believe that, because she already had a good reputation as a pianist. She had won the district bronze medal, the highest reward she could obtain in her school. After she had palmed awhile, ten minutes, I held the test card close to her eyes and asked her what she saw. She said the white card was covered with black spots. Quickly I told her to palm again for a short time. After about five minutes I told her to look at the card again, and this time she recognized the large E of the 200 line. We all rejoiced, because the rapid movement of her eyes from side to side had stopped temporarily.

Then I placed the card on my desk about a foot away from her, and told her to palm again. When she opened her eyes later she saw the 100 line letters.

The next time she came I placed her two feet away from the card. After palming a short time she read the 70 line letters. She palmed again, and this time her vision improved to 2/50.

The chaperon for the two girls did not realize that it was possible for Rosalie to read the alphabet or to read figures. She taught Rosalie at my suggestion. Her vision improved after six visits to 1/40 for the Pot Hooks, the letter and figure cards. The nystagmus had disappeared permanently. I am sorry that she was unable to visit me until she was cured.

**Palming improves  
clarity of vision.**

## ELEANOR

Eleanor's vision with each eye was 3/100. Her vision was improved by palming and by the long swing. She could make out figures much easier than letters, so I placed the figure test card at five feet from her eyes. While she was moving her body from left to right, she was told to glance at the figure I was pointing at. She was told not to look at the figure longer than a second, otherwise she would be tempted to stare, and her vision would be lowered. She practiced this for a few minutes and her vision with both eyes improved to 5/50. Her left eye, which had atrophy, was greatly relieved by the sun treatment.

Every time she came for treatment, which was once a week usually, her vision improved for another line of the test card. Changing cards helped to improve her vision also. After the regular C card was used, we tried the Pot Hooks card. Eleanor never had anything to say, but did just as she was told. When her vision improved and she became able to read small letters and figures, she would smile and become very much excited. In one week's time her vision improved to 6/20 with both eyes. Then I gave her small type, called diamond type, and asked her to hold it six inches from her eyes. She could see black spots on the little card, she said, but nothing more. I gave her the sun treatment for a few seconds, and right away she became able to read the fine print.

Later we used a black card with white letters, which Eleanor liked very much. I placed it ten feet away from her and I noticed that she turned her head over to one side in order to read the letters. The distance of only one foot caused her to strain while trying to read the strange card. I directed her to swing and blink as she flashed the white letters I was pointing at. In less than a half hour she read the letters one line after another with her head perfectly straight. She was given the sun treatment about six times in one hour, and was encouraged to read the card after each treatment, and before she left me her vision had improved to 6/20.

I did not see her again for a few weeks, and I feared that she would not get along so well by herself. When I saw her again she surprised me by reading all the different cards she had practiced with and she was able to keep her head perfectly straight. Her vision had improved to 6/10. Eleanor plays the violin and sings. Always when I guided her in reading the card with her head straight, I reminded her of her violin and how well she could play something that she knew. This always helped to improve her vision.

Eleanor and Rosalie left the city for a time, and I did not see them again.

Long Swing

Swing and turn left and right, blink, glance at a letter on the chart.

Read small Diamond type at 6 inches.

Sunning,  
Face the sun,  
eyes closed.  
Move the  
head side to  
side, up and  
down.

Thinking of favorite hobby (playing the violin) relaxes the mind, eyes, improves the memory, imagination and clarity of vision when reading the eyechart.

Black Eyechart with white letters.

Sun Treatment

Pull the upper eyelid up, look down, pupil away from sun, let the sun shine directly on the upper white area of the eye. Then, release the upper lid, look up, head back and pull the lower lid down and let the sun shine on the lower white area of eye.

## The Sun as a Cure for Imperfect Sight

By EMILY A. MEDER

The article reprinted below gives us the opportunity to dwell in a little more detail on the benefits of the sun for all cases of defective vision. Although this subject was discussed in the January issue, too much stress cannot be laid on it:

### SIGHT RESTORED BY SOLAR ECLIPSE

Lodi, N. J., January 27.—As the result of looking directly at the eclipse of the sun last Saturday, Louis Pretola, 54 years old, professes to have regained his sight after having been unable to see without glasses for seven years due to cataracts.

Pretola had undergone four unsuccessful operations for removal of the cataracts.

After he had gazed at the sun without smoked glasses he suffered severe pains, but within a few hours his sight began to return to normal and he discarded the strong glasses he had worn for seven years.—Cincinnati "Inquirer."

Note by Clark Night: Eye Doctors have stated for years that looking at a solar eclipse without eye protection can cause eye/vision impairment. I do not advise looking at a eclipse, even though in this case it helped the persons vision.

I HAD an experience last week, which served to bring home more forcibly, the great healing, alleviating power of the sun.

I was to spend a few days at the ocean-side, and arrived in the midst of a terrific storm. The sky was black, the rain came down in great sheets, and the waves beat ceaselessly against the rocks under my window. It was a little frightening, watching this, but soon the rhythm of the gathering, rising, and receding of the huge billows seemed to form a natural swing. I could relax by moving forward and backward, almost imperceptibly, with the rise and fall of the waves.

The next day was beautiful, with the ocean smooth and peaceful, and the sun shining gloriously on everything. I left the hotel for a stroll along the boardwalk, but upon emerging from the dim light into the blazing sun, I was blinded. I tried to open my eyes but found them straining to close, and it seemed as though a great flashlight was being focused on my eye-balls. The sudden strain brought on a severe headache. Perhaps it was the glare of the sun on the water, or it may have been the intensified brightness after a dark and gloomy day that caused the sudden blindness.

There was a summer house about fifty yards off, overlooking the ocean. I made for that, and sat down, facing the water, and with the sun beating down on my closed lids. After about fifteen minutes of this sunbath, I was able to open my eyes with comfort, and look across the water. The glare was gone, but I found it difficult to look directly at the sun. I just lazily shifted my glance from one object to another. A flock of sea-gulls amused me for about an hour. In my interest in them, I forgot about the sun's effect on my eyes, and caught myself glancing straight up, watching the flight of a particularly energetic pair of birds. There were so many of them, they were all so busy and active, that my eyes were not still for one moment.

I palmed again for about ten minutes, and when I removed my hands, I saw a fleet of four sailing ships away off in the distance. I could barely discern the outline, but this was more remarkable, because I did not see them when I first sat down, and they were much nearer then.

Before I left, I could look directly at the sun for about five seconds, but had to keep it swinging. Another unusual feature was that the sun, instead of being a blazing red, as it first appeared, changed to a silver or white color. This was more relaxing and soothing. Dr. Bates informed me that **the sun always looks white to those with perfect sight.**

That first attack was the only one I had during my stay. I enjoyed the sun and glanced up at it whenever I thought to do so, without discomfort. Pain and tension immediately disappeared.

With the spring on the way, there will be more opportunity to give your eyes a sun treatment. Try it.

### Report of the League Meeting

By MABEL A. YOUNG, Secretary

THE regular meeting of the Better Eyesight League was held at 383 Madison Avenue, Tuesday evening, February 10th. Miss Secor our new president, presided, and welcomed the new officers of the League.

It was moved and seconded that the time of the meetings be changed from the second Tuesday to the first Tuesday, the change to take effect in April. The motion was carried.

The speaker of the evening was Captain C. S. Price, of London. He said that there is a Better Eyesight League of many members in England, but that they do not hold regular meetings, as is done here. Each member is doing definite work. Having no direct contact with Dr. Bates, they have gained their knowledge of his methods from an intensive study of the book. It is interesting to note that the different workers more or less isolated, gained similar results by different methods.

The members of the English League have tried to avoid anything that would cheapen the work. They try to hold it above any idea of empiricism or quackery, and take their work where they find it near at hand. They fast cured their relatives and neighbors. They worked for results, got them, and the news has spread.

Captain Price spoke more particularly of his own work, and that of his colleague, Miss K. Beswick. He said that back of all eye troubles are mental factors. He has given much thought to the psychological side of this work. People need, first of all, to be made to

realize the value of sight. Relaxation is a prime necessity, and the ways of securing it are numerous. No two patients respond to treatment in the same way. The teacher must approach them on their own ground. He would not use the same method with an artist as with a mathematician. The body must also be considered as a whole, and the eye as a part of the body. The very poor people commonly live under conditions which make relaxation impossible, and many of them visit the clinic and ask to be allowed to merely sit there and rest. A tired person must rest before he can relax.

Thousands of poor patients are treated in the free clinic each year, some of them having been discharged from the hospitals as incurable. Myopia is rare among them, and cataract and blindness are common. The work was first carried on in institutions, but as **its unorthodox character became known, Capt. Price and Miss Beswick were debarred from working there.** The patients followed them however, and visited them in their free time at the office.

Eye not used 18 years — restored, vision improving

Captain Price described several cases. One man had his eye removed by an operation. The other had not been used for eighteen years, and had atrophied. After six weeks practice, the patient was able to open the lids an eighth of an inch. The eye when seen was a horrid looking mass—inflamed and sunken. It is now fully developed, has perception of light, and he can distinguish colors.

A lady who had been blind eight and a half years from glaucoma, and who had been discharged from the hospitals as incurable, now plays cards without glasses and takes her friends to see the shops.

Captain Price's talk was followed by a discussion, when he answered the members' questions. Dr. Darling, Dr. Achorn, and Mr. Husted spoke, the latter telling of his wonderful success with this method in the schools. Mrs. Lierman described several interesting recent cases from her clinic.

The members of the League were concerned to learn that Dr. Bates is seriously ill in the hospital, due to an operation on his arm. Before the meeting adjourned, Mrs. Marsden proposed that the League send flowers to him. It was voted to do so.

## Suggestions to Patients

By EMILY C. LIERMAN

THERE are many reasons why some patients do not respond readily to treatment. A few of these are listed below.

1. If the vision of the patient is improved under the care of the doctor and he neglects to practice when he leaves the office, what he is told to do at home, the treatment has been of no benefit, whatever. The improved vision was only temporary. Faithful practice improves the sight to normal.
2. If the patient conscientiously practices the methods as advised by the doctor, his vision always improves. This applies to patients with errors of refraction, as well as organic diseases.
3. For squint cases we find that the long swing is beneficial to adults and to children.
4. When a patient suffers with cataract, palming is usually the best method of treatment, and should be practiced many times every day.
5. All patients with imperfect sight unconsciously stare and should be reminded by those who are near to them to blink often. To stare is to strain. Strain is the cause of imperfect sight.

## Announcement

Beginning with April, 1925, the BETTER EYESIGHT LEAGUE will hold its regular monthly meeting on the first instead of the second Tuesday.

The March meeting will be held on the second Tuesday at 8 o'clock, as usual. This falls on the tenth. The League meets in the Central Fixation office, 383 Madison Ave., and the many ways of improving the sight are discussed. Everybody welcome!

## The Two Princes

By GEORGE GUILD

A YOUNG prince and his brother were confined in a tall, stone tower far away from their home. The jailer had received orders to feed them very little, and if they died he would receive a big reward. Under these circumstances the two princes did not have an enjoyable prospect. Both of them were famous throughout the kingdom because they had seen fairies. Furthermore they had taught other young children how to see fairies. They spent a great deal of their time in the top of the tower looking for the fairies in the distant woods and in the green fields close by. This improved their sight and the improvement in their vision was followed by an improvement in their ability to remember, imagine, and to plan things to help other people as well as themselves. If you look for the fairies, sooner or later you will see them. The desire to see the fairies is a great benefit to the eyesight. They wrote many letters to their friends asking to be rescued. The fairies visited the young princes frequently, and advised them to treat the jailer very kindly and to notice the result. It was not long before the jailer, under the influence of the kind treatment recommended by the fairies, fell in love with the two boys, and treated them better than most fathers treat their children.

One day, as they were looking out of the window high up in the walls of the tower, they saw coming towards them an army of children. It seemed that all the musicians in the country were with them. The dancing and the laughter were very considerable. When the children reached the tower, without the permission of the jailer, many of them rushed in and overflowed the place. Those who couldn't get in, stayed outside and made an awful lot of noise. Suddenly from the woods an army of fairies appeared, all dancing and singing and happy as they could be. The children welcomed them, clapped their hands and invited them to dance on the green. While the fairies were dancing and the children were trying to imitate them, the princes came down from the tower and danced with them. The jailer was so taken up by the unexpected

attentions of the children that he forgot all about his prisoners.

One of the fairies said, "Let us play 'Follow my leader'." She started off to run, and all the others behind her, but there were so many that they lost the leader and found themselves just going back toward London.

About this time the jailer appeared, and in a loud voice called out that he had something to say. So they placed him on top of a pillar where he could be seen by everybody. "My friends," he said, "I am only a poor jailer. Some wicked men in London came to me and offered me money to murder the two princes, because after they were killed their cousin would ascend the throne. But the fairies treated me so nicely and the princes treated me so nicely that instead of being their enemy, I am now their friend. Follow me to the house of those wicked men, and we will put them in a jail from which there is no escape."

All the men and women and the fairies and the children followed him to the house where the wicked people lived, and they were all dragged out and thrown into jail and placed under the care of the jailer. Then the princes and the fairies and all the people rushed up to the palace of the king and queen, and drove away the wicked soldiers who were holding them prisoners. The two princes were restored to their parents and there was great rejoicing. The king and queen felt very much indebted to the fairies because it was through their activity that things had all turned out so well. The two princes improved their sight very much by looking for the fairies; and the eyesight of the children in the kingdom was improved because they had to imitate the princes and be in the fashion.

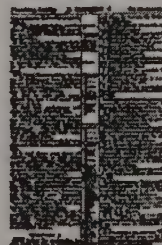

## Read Fine Print

ALL of our imperfect sight is just the result of our using our eyes wrong, and permitting bad habits to grow on us. Staring is only a bad habit, but it causes a great deal of trouble. When it is stopped and the eyes are rested by palming and blinking, the sight is immediately benefited.

Bad habit number two: The reading of large type in preference to finer print. It requires more of an effort to see a large letter than a small one, strange as it may seem. When you look at the big C on the Snellen Test Card, you don't see it all at once. You have to look at one part best, the hook on the upper right hand corner or the curve on the left side. You cannot look at the hook, the space on the right and the curve on the left side all at once. Some people think they see it at the same time, but they do not. Their eyes shift from one point to another, unconsciously.

Fine print is a benefit because it cannot be read while the eyes are under a strain. They have to be relaxed. For instance, in reading the chapter printed below, you cannot accomplish anything by staring at the letters, or screwing your face into a knot. Do not look at the letters but at the white spaces between them, and imagine them whiter than the margin. Blink and shift constantly to avoid the stare. If your eyes feel strained, stop and palm. You will notice that where it all looked blurred before, a word will appear clear and distinct. By constant practice more words clear up, until the entire chapter can be read easily.

## S. MATTHEW 4 BEATITUDES

Shift dot to dot  
(part to part) on the C.  
See one small part of the  
C darkest black and  
clearest at a time in the  
center of the visual field.  
The center of the visual  
field moves with the eyes  
as the eyes shift part to  
part on the C. Shift point  
to point on the top right  
hook in the blue circle.

## Questions and Answers

Q—Explain what you mean when you say "imperfect sight, imperfect memory."

A—If you see an object imperfectly, blurred or gray instead of black, you cannot remember it perfectly. You will remember it as you see it.

Q—My eyes feel fine after I palm and let my mind drift on various black objects. The period is more difficult though.

A—Perfect mental pictures of ordinary objects means a perfect mental picture of a period. To try to see is an effort or strain, and produces defective sight. Shift point to point on the period. See it move 'The Swing'

Q—By blinking do you mean shutting and opening the eyes quickly, or is done slowly, like a wink?

A—Blinking is done quickly, and not slowly like a wink. Watch some one with perfect sight do this unconsciously, and follow his example.

Q—How can one overcome the stare if it is unconscious?

A—Blink consciously, whenever possible, especially when reading. Never look at an object for more than a few seconds at a time. Shift your gaze.

Q—I have noticed when I palm that my eyeballs hurt from the pressure. When I loosen this tension the light filters in.

A—Palming is done correctly with the fingers closed and laid gently over each eye, using the palms like a cup. If this is done properly there is no pressure and the light is shut out.

Allow the hands to relax, no pressure on face/eyes, no muscle tension in hands, head, shoulders, neck, body. It is ok if a little light shines through the hands.

## MATTHEW 4

in whom I am well pleased."

## CHAPTER 4

THEN Jesus was led up by the Spirit into the wilderness to be tempted by the devil.

2 And when He had fasted forty days and forty nights, afterward He was hungry.

3 Now when the tempter came to Him, he said, "If You are the Son of God, command that these stones become bread."

4 But He answered and said, "It is written, 'Man shall not live by bread alone, but by every word that proceeds from the mouth of God.'"

5 Then the devil took Him up into the holy city, set Him on the pinnacle of the temple,

6 And said to Him, "If You are the Son of God, throw Yourself down. For it is written: 'He shall give His angels charge over you,' and, 'In their hands they shall bear you up, lest you dash your foot against a stone.'"

7 Jesus said to him, "It is written again, 'You shall not tempt the LORD your God.'"

8 Again, the devil took Him up on an exceedingly high mountain, and showed Him all the kingdoms of the world and his glory.

9 And he said to Him, "All these things I will give You if You will fall down and worship me."

10 Then Jesus said to him, "Away with you, Satan! For it is written, 'You shall worship the LORD your God, and Him only you shall serve.'"

11 Then the devil left Him, and behold, angels came and ministered to Him.

12 Now when Jesus heard that John had been put in prison, He departed to Galilee.

13 And leaving Nazareth, He came and dwelt in Capernaum, which is by the sea, in the regions of Zebulun and Naphtali,

14 That it might be fulfilled which was spoken by Isaiah the prophet, saying:

15 "The land of Zebulun and the land of Naphtali, by the way of the sea, beyond the Jordan, Galilee of the Gentiles;

16 The people who sat in darkness have seen a great light, and upon those who sat in the region and shadow of death light has dawned."

17 From that time Jesus began to preach and to say, "Repent, for the kingdom of heaven is at hand."

18 And Jesus, walking by the Sea of Galilee, saw two brothers, Simon called Peter, and Andrew his brother, casting a net into

Blink, Relax, Shift.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

April, 1925

### Floating Specks (Muscae Volitantes)

WHEN a patient stares or strains to see by looking at a light-colored surface he may see, or imagine he sees, floating black specks, strings of black thread or small light-colored globules resembling tears. The floating specks may be apparently a quarter of an inch or more in size and they may be of any shape.

The ability to see or imagine floating specks may occur in children or in adults of any age. Some children have been known to lie on their backs on the ground, look up at light colored clouds and amuse themselves for hours by watching what appeared to be floating specks.

Many nervous people have been made very unhappy, consciously or unconsciously imagining that they see these floating specks.

The cause of floating specks is an imperfect memory of perfect sight. Persons with normal vision who have never been conscious of floating specks can be taught how to imagine them by straining—to imagine letters, colors or other objects imperfectly.

Conversely, patients who are conscious of floating specks are unable to imagine them and perfect sight at the same time.

In the treatment of floating specks it is important to convince the patients thoroughly that they are only imagined and not seen. It helps very much to impress on the patient's mind that to see these floating specks requires a sufficient strain to lose a perfect imagination of all objects seen, remembered or imagined at all times and in all places.

When the mind and eyes are relaxed, the mind/brain shuts off the appearance of floating specks, floaters. Shifting, saccadic shifts and other natural eye movements, central fixation removes floaters.

Good diet, healthy food, natural food source chelation type diet/food and **fasting** cleans out the arteries, capillaries, lymph system...all organs removing fat deposits, toxic metals... A cleansing diet helps remove floaters. Apples, apple cider vinegar with honey (organic).

Improved circulation to/in the eyes and strengthening the capillaries eliminates floaters.

Orange, grapefruit peels with the white part and skin keeps arteries, veins, capillaries strong.

Avoid processed sugars, fructose, aspartame, hydrogenated and other artery clogging fats.

Floaters often are seen when the vision is unclear, eyestrain and/or the mind is stressed, strained, outer eye muscles tense placing pressure on/in the eye.

Most floaters are said to be caused by debris floating in the eyes vitreous humor remaining from development of the eye before birth.

These are harmless. Many people of any age, children and adults, experience floaters.

Hormone fluctuations in men and women can cause temporary floaters. Withdrawal from caffeine and other addictive substances, use of prescription and non-prescription drugs. Sinus congestion, pressure on the eyes.

Eyeglasses cause floaters and impair eye health. Cornea surgery causes floaters.

See Floating Specks - Better Eyesight Magazine - October, 1919. Dr. Bates tries to get a patient that sees floating specks to realize there is nothing wrong with his eyes and to stop worrying!

Always be safe and check with your eye doctor. Usually the eye doctor finds the eyes in good health.

Floaters move, especially when the eyes move; when the person tries to look directly at them, they move away from the center of the visual field. This is good; the central field stays clear. When the eyes shift relaxed, easy, faster, perfectly natural, automatic, and the person stops thinking about and looking for the floaters, the floaters disappear.

Dirt, dust on the cornea can cause a different type of floaters and usually obstructs the vision. Eye makeup, poor air quality, dry air, cornea injury, contact lenses and solutions can cause this. Contacts and solutions can cause cornea injury, infection, scars.

On certain days when the weather, atmosphere is just right, when looking into the sky, the eye can see what looks like tiny fast moving energy particles, like moving electricity, lights in the air. Scientists state this is true energy in the atmosphere. Spiritual teachers state it is one type of many other energies that exists in space.

When light contacts the eyes at certain levels of dimness, brightness, angles, certain types of light, or looking through certain types of glass: the blood corpuscles flowing in the capillaries in the retina can be seen. These are not the usual floaters.

Some people see tiny dots of blue, purple, white, any color light flash for a split second. This usually indicates eyestrain, neck tension from looking down straining the eyes a long time, the need to rest the eyes and use the eyes properly, good posture, vision habits, shift, blink. Low potassium, dehydration, poor diet, too much caffeine, soda can cause this.

Eye injury, disease, detached retina and other abnormal eye conditions can cause floaters.

Seeing many flashes, sparks, flickering lights, large dark spots, soot, dust raining down can indicate detached retina. Contact a eye Doctor immediately. Dr. Bates has successfully treated detached retina.

Flashing, moving, shimmering lights, sparks can also indicate migraine headache, sinus headache, pressure.

Floating Specks.

Girl lying in the grass on a hill looking at the blue sky, white clouds and seeing floaters, imagining they are angels or outer space aliens, secret friends with magic powers that protect her.

## Quick Cures

By W. H. BATES, M.D.

QUICK cures are desirable. At the same time let me hasten to state that we must use the word "cure" with great care. It means a great deal more than most physicians realize. A patient's definition of a cure is more complete, more thorough, and more lasting than he realized or remembered at his first visit.

To promise any patient a cure is unwise from a scientific standpoint. In my work I take particular pains to make the patient understand that I do not expect or guarantee a cure in any case. The most I say to them is "Yes, I have cured people much worse than you, but that is no guarantee that I can give you the slightest benefit."

This seems to eliminate a certain amount of subconscious antagonism on the part of the patient, who may consciously say that he desires to be cured, but deep down in his heart feels unconsciously, "I don't believe you can do it with my help, and I am quite sure you can't do it if I oppose you."

Like the Irishman who said "he was willing to be convinced, but he would like to see the man who could do it."

Quick cures have their disadvantages. A patient feels that since his benefit came easily, now, with his good sight, he can go off at any time he likes and have a spree, in which he stares and strains and uses his eyes to his heart's content without any danger of a relapse. He forgets that all persons with normal vision can acquire imperfect sight at any time. The attending physician must be on his guard when referring to those patients who have been cured quickly, and not give the impression that it is an easy thing to do, because too often those patients who know about quick cure cases expect to be cured themselves in the same way as quickly and as permanently. If they are not, they are disappointed, and they have a way of expressing that disappointment which hurts. Personally I am very much upset every time a patient surprises me with a quick cure, because of the favorable criticism which may follow and which is seldom desired by the attending physician. If we could only practice quick cures in favorable cases and not have to struggle with the obstinate ones, things would get along perhaps better.

It is well to bear in mind that most quick cures happen when least expected and we do not always know what particular thing accomplished it.

One question is often asked: "What kind of cases are most quickly cured?" I do not believe that we have sufficient facts to answer this question at all intelligently, because mild cases of imperfect sight may require long periods of time—years—before recovery, or a permanent recovery, occurs. I have a number of patients whose amount of imperfect sight is very small, indeed, and yet after some years of more or less continuous treatment they are still not permanently relieved. In other cases a large amount of near-sightedness or far-sightedness without any special reason, practicing the same method of treatment, would obtain a permanent cure at one visit. I wish I knew why.

Quite a number of patients with imperfect sight for the distance, and also unable to read the newspaper at a near point, have been permanently cured after a half hour or more of palming. Other cases have practiced palming apparently just as faithfully without much if any relief after many months. It would be perhaps a good thing to know why palming was so very beneficial in some cases while in others the benefit was imperfect.

One patient 60 years of age with imperfect sight from **cataract**, whose vision was not improved at all by glasses, obtained normal vision without glasses at the first visit. The cataract and all the other troubles disappeared almost immediately after palming. It was interesting to learn that this patient had worn quite strong glasses for nearly fifty years. During this time even with his glasses he suffered pain, fatigue and other discomforts. He told me that all he wanted or that he would be satisfied with, was the cure of the cataract, so that possibly, with glasses, he could do his work. The very thought of it made his face brighter, but when after palming he obtained not only a cure of his imperfect sight but of every other symptom he could remember, he certainly was grateful and he showed it in his face.

### Man 106 years Old Cures Cataract With Palming

Another patient said he was 106 years old. His vision for distance was poor and he was unable to read fine print with or without glasses. He had **cataract** in both eyes, so opaque that no red reflex could be seen in any part of the pupil with an ophthalmoscope. He was placed in a dark room and told to close his eyes and keep them closed. At the end of a half hour his vision was improved to 10/10 and he read diamond type at six inches without glasses. He was told to repeat this treatment frequently during the day in order to avoid a relapse. He came back at the end of a week with his vision still further improved. As he went out of the office without an attendant to guide him he stopped and spoke the only words I ever heard him say: "Doctor, you did me good." I wish I knew what I did or did not do. It would be a great satisfaction to me to find out how the patient by closing his eyes for a half hour improved his sight so much and so quickly. A large number of other patients have been told the same thing; the same words were used as were spoken to him, but the results were seldom repeated.

It is well to emphasize that under the most favorable conditions quick cures are exceedingly rare. They generally occur when least expected, but when they do occur the definition of the word "cure" includes a great many more benefits than the patients expect.

One of the quickest cures I ever had was in the case of a very ignorant man who was suffering from sympathetic ophthalmia. At school, he told me, he could never understand fractions, and yet I found that he had the most wonderful imagination in my experience. Although he could not tell the big "C" at ten feet, when I brought it up close to him he said that he could imagine it and could imagine it perfectly. Knowing that it was a big "C," he was able to imagine it perfectly at ten feet, and when I told him that the first letter on the line below was an "R," he became able almost immediately to imagine it so perfectly that he could imagine he saw a letter "B" on the same line, and a letter "T," the

Happy thoughts,  
mental pictures  
when palming.

Palm and remember,  
imagine a pleasant  
object, scenery and  
shift throughout the  
scene; from object to  
object, part to part on  
objects. See objects  
in motion, action like  
a real life movie in  
the mind, in color,  
clear.

first letter on the line below. He kept insisting that he did not see any of these letters. He only imagined them.

When I pointed to the first letter on the bottom line he said it all looked black. When I told him that the first letter was an "F," at once he said he could imagine it perfectly, and much to my surprise after the perfect imagination of that letter "F," he became able to imagine in turn the other letters on the bottom line which he did not know. He kept insisting that he did not see these letters—that he only imagined them. But always when he imagined perfectly one letter on the Snellen test card, the whole card became clearer and perfectly distinct and he could see or distinguish neighboring letters which he did not know. His imagination improved his sight to normal. To walk around the room without running into the furniture and to see surrounding objects, all he had to do was to imagine one letter of the alphabet perfectly.

Many of my patients have been teachers in the various universities, have the highest intelligence and are authorities in their fields, yet whose imagination of mental pictures was very poor.

## Stories from the Clinic

### No. 61: Quick Cures

By EMILY C. LIERMAN

PATIENTS who are cured quickly of imperfect sight are those who become able to improve their memory and their imagination quickly and without effort. A little girl named Madeline, aged ten years, came with her mother, who was very anxious to have her child cured without glasses. The mother had been notified by Madeline's school teacher that her little girl could not read correctly what was written on the blackboard from her seat, which was about ten feet away. She was one of the daintiest little girls I have ever seen. I can imagine her as one of the white fairies written about in our little magazine, which I believe a great many children enjoy. I feel sure that there are many mothers among our subscribers and that they realize the relaxation and rest which is given to the child-mind as the mother reads about the good fairies just before the sandman comes.

This is how Madeline was cured in one visit. She was placed ten feet from the test card and she read all the letters correctly down to the twenty line, 10/20, but the letters were not clear and black to her. She was told to palm for ten minutes or so. Then she read the card again, and this time the letters appeared clear and black. The mother was told to notice how she stared when trying to see one of the smaller letters of the fifteen line. I told Madeline she must blink her eyes all the time to prevent staring, which always lowered the vision. As she glanced at the letters each time she moved to the left and then to the right, not forgetting to blink her eyes, her vision improved to 10/10. She was placed in another room, fifteen feet from another card, which she had not seen, and without a stop she read all the letters of the card. Now, I wanted to find out if I could improve her vision further with the aid of her memory. I told her to close her eyes and palm and remember something she had seen without effort or strain. She answered: "I cannot think of anything just now, and the more I try the less am I able to do as you ask me." I asked her then to tell me what lesson she liked best at school. "Oh! I just love arithmetic," she said. I asked her if she would add up some figures for me while she was palming and she answered, "Yes." I started with easy figures at first, like nine, three and eight. She added as quickly as I announced the figures. Then I made the lesson more difficult, but she did not once make a mistake. All this time she was smiling and enjoying the whole thing. We kept this up for about fifteen minutes, and then while her eyes were still closed, I moved the test card as far away as I could place it, which was eighteen feet. Madeline was told to remove her hands from her eyes and stand and swing as she did before. She read every letter on the card correctly. Her vision had improved to 18/10 by the aid of her memory for figures.

Madeline was cured quickly, because she was able to remember figures perfectly. Her mental pictures of them were perfect. Her mind was relaxed, and by the aid of the swing and remembering to blink often, as the normal eye does, she had no more eyestrain.

Palm and improve the clarity of vision with the memory of something seen clear without effort, strain: The girl remembers, imagines a favorite thing at school—Arithmetic. She easily sees, remembers, imagines perfectly and adds numbers in her mind. The mind, body, eyes relax. Memory, imagination of clear mental pictures is perfect. Vision is clear.

Blink often, relaxed, easy. Blinking prevents staring, strain, effort to see and unclear vision. Blinking causes the eyes to shift automatically. Blinking coats the eyes with healthy tears and improves the eyes production of tears. A coating of tears on the eye, cornea improves the clarity of vision and protects the eyes, keeps them moist.

After palming the girl stands 18 feet from the test card, 'swings' moves the body left and right and blinks while glancing at (a quick easy shift upon) letters on the test card and sees them clear.

A little boy, aged seven years, was brought to me not long ago. His nurse, who was extremely fond of him, did not want glasses put on the little fellow. He told me very emphatically that he just would not wear them. No one would dare put them on him, he said.

His little forehead was a mass of wrinkles as he tried to read even the largest letters of the test card at ten feet. I asked the nurse to sit where she could watch him at the start and then see the change that I was sure would come to his face after he was taught to read without effort or strain. With each eye separately he read 10/50. As he tried to read further he wriggled and twisted his little body around in the big arm-chair where I had placed him.

"Now," I said, "little man, just close your eyes and place your hands over them and shut out all the light. Sit still, if you like." "Oh," said he, "I like sitting still if I keep my eyes covered, but I don't like doing it too long." I said: "All right, keep them covered for a little while and I will read you a fairy story that tells something about the elephant, too."

That was all that was necessary. My patient sat perfectly still as I read the whole fairy tale. The nurse remarked that for a long while he had not been able to sit still for more than five minutes at one time.

After the fairy story was read, I told the little chap to stand, feet apart, with eyes still closed, and I guided him in moving his body from right to left until he became able to do it gently by himself. Then he was told to open his eyes and keep moving or swinging his body to the right and then to the left. He was directed to blink his eyes while doing this. He exclaimed, with great surprise: "My, the card and letters seem to be moving opposite." I said, "That's right, my boy; now follow my finger as I point to the letters." He did, and to our surprise he read the whole card without a mistake, 10/10. The wrinkles in his forehead were gone. I told the nurse to help him many times every day with the test card just as I did. She promised also to bring him back to me if he had any relapse. So far I have not heard from her. I do believe my little boy was cured in one visit.

## Hungry Fairies

By GEORGE M. GUILD

ONCE upon a time a young man, a reporter, found himself in a Southern city without a cent of money.

He desired to take passage on a steamboat for New York. As the time came for the boat to sail, and not having met anyone he knew, he finally plucked up sufficient courage to talk to the Captain about it. The Captain listened in sympathetic interest, being one of those jovial, happy kind of people who are often interested in somebody else besides themselves, interrupted the reporter and asked him: "What paper do you write for in New York? Do you suppose that you could write a story about our line of steamers which would be a good advertisement for our boats?"

The reporter being very anxious to get back in some way to his home town answered the Captain as best he could. The Captain then took out a ticket from his pocket, handed it to the reporter and told him that if he would promise to write a good advertisement of his boat which would encourage an increased number of people to travel by his line that he would be satisfied.

The reporter took the ticket and in his gratitude promised whatever the Captain desired. The reporter had the ticket which insured his passage home, but he did not know what he could do for food as he had no money to purchase it. The steamer left the dock and headed for New York. Lunch time came and, in order not to make himself conspicuous, he sought an unusual part of the boat where there were no people who might ask embarrassing questions.

He sat down on a steamer chair, closed his eyes and tried to forget that he had a stomach and that he was hungry. As he sat there resting, a fairy came dancing along the deck, came close up to him, patted him on the back and invited him to get up and dance with her. As there was no one around he accepted the fairy's invitation, and so they danced forward and back, sideways and round and round. And as they danced other fairies appeared and danced with him. He enjoyed the dance very much and was sorry when some of the passengers appeared and the fairies vanished.

After a while he began to feel hungry again, and at the same time he remembered how the fairies, when they danced side to side and other directions, swung their bodies as they danced. Being small fairies the swing was very short, and when he remembered the swing of the fairies he became able to remember the swing just as short. As he swung or imagined he was swinging the hunger left him and he smiled and was pleased. Some of the passengers asked him how he enjoyed his lunch. I am sorry to say that he lied about it and told them that he wasn't feeling very well and thought he would omit his lunch.

They imagined that he was more or less seasick, smiled and went away and left him. The afternoon passed and supper time arrived and again he sought an unoccupied part of the boat. Again he found a steamer chair and occupied it as previously, and while there the fairies again appeared and persuaded him to dance with them as he had done before.

The more he danced the better he felt, and as the dance went on and he practiced the swinging, side to side and other directions, he quite forgot his hunger, and when he did that the fairies smiled and encouraged him to keep on with the swing.

The next morning at breakfast time his hunger had become worse than it was the day before. Again the fairies appeared and told him that they were very hungry, that they were very anxious to be carried by the steamer to their home in New York. From there they expected to go to some of the parks and obtain some food—being fairies they did not need very much food. What they wanted was quality more than quantity. The reporter told them that, for him, he was willing to pass up the quality of the food provided he obtained sufficient quantity.

They all laughed at this and began to dance more rapidly than ever before, and in order to forget his hunger the reporter danced with them just as fast as he could.

And so the days passed for him quite rapidly. At times he found it difficult to explain why he missed so many of his meals. The help of the fairies made it possible for him to forget his hunger at all times provided he remembered or imagined the swing of the hungry fairies.

In due time the steamer reached New York. When the gang plank connected the steamer with the dock, our reporter started to

Long Swing in front of the Eye chart.  
Start by facing the chart.  
Swing and turn the body left and right. The body, head/face, eyes move together, at the same time, in the same direction.  
See the eye chart appear to move opposite the movement of the body, head, eyes.  
Oppositional Movement.  
Do the sway (Rock) in front of the chart and see a smaller movement.

Tiny Fairies doing the Long Swing, Sway. Fairies show a tiny movement, like the tiny Saccadic shifts of the eyes which bring very clear vision.

leave the vessel with the other passengers. When he came to the man who takes the tickets he handed out his ticket and started to walk away. But the ticket man stopped him and looked at the ticket in a puzzled way. He said to the reporter: "How is this? Your ticket gives you three meals a day on the boat and you haven't had a single meal punched. What's the matter, Wasn't the food good enough for you?"

The reporter answered: "Yes, but you see I am under a diet and did not have to take my meals regularly. You'll find it all right," and then ran down the gangplank and disappeared in the crowd with a feeling of something which he could not describe.

The memory of the hungry fairies, however, was a pleasant memory. He walked along practicing the swing until he met a friend who saw to it that he got a good square meal. The reporter told his friend the story of the fairies and how they had helped him to endure the hunger and made his trip a pleasant one with their sympathy, kindness and the swing.

His friend laughed so long and so heartily that the reporter was quite annoyed. It amused his friend very much to hear that he carefully avoided the dining room, and was ravenously hungry for a whole week—with a paid meal ticket in his pocket!

## Concentration and Relaxation

By LAWRENCE M. STANTON, M.D.

I KNOW of no writer who has so clarified the murky philosophy of concentration and relaxation as has Dr. Bates, and yet the final word has not been said, as he himself would undoubtedly avow.

Therefore, but with humblest intention, I offer a few thoughts upon the subject which is of the utmost importance to those who are striving for better eyesight.

### Concentration - Attention

To my patients I have forbidden the practice of concentration, saying that the very word suggests strain, or else I bid them modify the dictionary's definition. I have reasoned that if by concentration you mean, as Dr. Bates says, doing or seeing one thing better than anything else, you may speak of concentration; but if by concentration you mean, as the dictionary says, doing one thing continuously to the exclusion of all other things, then you must abandon the practice as an impossibility.

Concentration, however, cannot psychologically be ignored, and recent psychology, I believe, has given us a new interpretation which is worthy of our consideration.

Attention underlies concentration, as that word is commonly used, and Ribot's statement of attention is very enlightening. Ribot says "that the state of attention which seems continuous is in reality intermittent; the object of attention is merely a center, the point to which attention returns again and again, to wander from it as often on ever-widening circles. All parts of the object, and then the reflections inspired by these various parts hold our interest by turns. Even when the attention is fixed on the most trifling material object, it works in just the same fashion." This is entirely in accord with Dr. Bates' statement; it is central fixation.

There are, however, two aspects of concentration to be considered—voluntary and involuntary. Voluntary concentration is an effort and, as Dr. Bates has so clearly shown, cannot be maintained without fatigue. The highest grades of attention, to which this brief consideration is confined, are involuntary, and involuntary concentration can be defined as "a psychological equivalent of attention minus effort." In ordinary attention—that is, in voluntary concentration—our thought holds the object in focus, whereas in involuntary attention (which we shall consider synonymous with involuntary concentration) the object holds our thought without our volition, perhaps even against our will. "Spontaneous attention is rooted at the very center of our being," and things that hold the attention captive, as in fascination, fixed contemplation, the Hindu's meditation and reverie are instances of involuntary concentration, and involuntary concentration is as effortless as the rising sun—it just happens. Then, there are those cases of miraculous quick cures of imperfect sight by one or another of Dr. Bates' methods, where it was enough for the patient to see the better course in order to be able to follow it, the idea and its realization occurring simultaneously, without effort, without volition even. Contrast this with the attitude "No, I see the better course and approve it, but I follow the worse." Involuntary concentration is displayed in the case of the insect, related by Fabre and quoted by Dr. Bates, which in captivity hung downward for ten months, its whole life's span, and in this position performed all its functions, even to mating and laying of eggs, apparently without the least fatigue.

Still another instance is that of **Napoleon**, who could work for eighteen hours at a stretch on one piece of work without the least fatigue. Napoleon speaks of his various affairs arranged in his head "as in a wardrobe." He says: "When I wish to put any matter out of my mind, I close its drawer and open the drawer belonging to another. The contents of the drawers never get mixed and they never worry me or weary me. Do I want to sleep? I close all the drawers, and then I am asleep."

The question, then, may be asked wherein does involuntary concentration differ from relaxation. If involuntary concentration and relaxation are not always one and the same thing, they often are psychological alternatives and not the opponents we think them.

To regard all phases of relaxation as purely passive is as erroneous as it is to say that concentration of the kind under consideration is associated with effort. Relaxation of the passive kind usually ends in sleep or sleepiness, as experienced by many patients after palming. Relaxation combined with action, on the other hand, may also be absolutely free from effort and strain.

(Dynamic Relaxation)

In any case it is the matter of effort and strain that concerns us most, rather than a question of concentration or relaxation. Victor Hugo speaks of "the calm and intense fixation of the eyes," and surely nowhere is intensity so impressive as in calmness. To be calm is not to be oblivious, and to be intense need not be to strain.

Another thought about relaxation is this: Obstacles to relaxation may prove sources of relaxation. An instance of which, is found in the noise that is keeping us awake when wishing to go to sleep. If we sufficiently relax, if we accept the disturbance and sleep in spite of it, not only is the obstacle overcome, but because overcome it in turn becomes rather pleasantly associated with going to sleep. When again we desire to sleep, we find the noise soothing rather than annoying, and really a source of relaxation instead of an obstacle to it. (A child deeply relaxed, drifting in and out of sleep, safe amongst the trees inside the edge of a field in a dugout up on a small hill, buried in a deep leaf pile, the sound of trains passing by along the river, crickets chirping, brothers, sisters playing in the distance, fire crackling in a old fashioned outdoor fireplace, smell of hamburgers.) The following quotation from Jean Kenyon MacKenzie's "Minor Memories" well illustrates how obstacles may become ministering angels. She writes of the stillness of the African forest:

"I remember that stillness. Many a time when I am in the subway I remember the ineffable stillness of the forest. I wonder to find myself where I am—so savagely circumstanced—so pressed upon by alien bodies, so smitten by noise. Traveling like this, in white man's fashion, you are certainly safe from the snakes, and the leopards, and the cannibal tribes of that other world where you

traveled in other fashions. Now that you are shut up so safely in the guts of Manhattan, your friends feel at ease about you—surely the sun shall not smite you by day nor the moon by night. And yet, perversely, in this perfection of safety you are intimidated. *Suddenly passive after your desperate adventures with traffic, you feel the hidden things of memory rise and flood your heart; you dream. You remember other times of day than the manufactured night of the subway and other ways of travel. And suddenly, in the indestructible silence that is the core of that incessant clamor, you hear a bugle calling in a forest-clearing that is half way around the world.*"\* Certainly a remarkable experience—what relaxation, what imagination!

Involuntary concentration without effort is equivalent to relaxation in action. If you can achieve such equilibrium; if you can perform your mental functions without strain as Fabre's little insect performed its physical; if you can, whatever your particular captivity, hang by your feet head downward without effort, then "be my friend and teach me to be thine."

Note: Some of the quotations in this article and some of its material are from "The Power Within Us," Charles Baudouin.

\* Italics mine.

## Announcements

### THE WORK IN ENGLAND

Capt. C. S. Price, of London, England, has been the guest of Dr. Bates for several weeks. Dr. Bates wishes to announce that he finds Captain Price thoroughly capable of curing imperfect sight by his methods.

## League Announcement

THE next meeting of the Better Eyesight League will be held at 383 Madison Avenue, on the evening of Tuesday, April 7th, at eight o'clock. The meeting will be of unusual interest to teachers and parents—in fact, to all who are interested in maintaining a high degree of visual acuity among children and adults. The speaker of the evening will be Percival S. Sprinz, D.D.S., who is the attending oral surgeon of the Hospital for Joint Diseases and chief of the Dental and Oral Surgical Department in the dispensary connected with the hospital. Dr. Sprinz will discuss "Eye Disturbances Due to Focal Infection in Teeth and Gums."

The members of the League will welcome information about this important subject, especially when presented by a League member. Dr. Sprinz discarded his glasses a year and a half ago; he is now able to read the photographic diamond type of the small Bible.

A cordial invitation to attend this meeting is hereby extended to friends of League members.

## Vivisection Contra-Indicated

By W. H. BATES, M.D.

MANY facts in physiological optics have been demonstrated by me, by experiments upon animals, all of which were dead. It is not possible to operate on live animals or on live fish, under anesthesia, and obtain reliable or constant results. The consciousness of the animal must first be destroyed by death. After an animal or a fish has been killed, the contractility of the muscles continues at the ordinary temperature for several hours. The results cannot be demonstrated at all accurately or constantly when the heart is beating and respiration is continuing.

## Questions and Answers

Q—Are floating specks serious? Sometimes they just flood my eyes like clouds of dust and greatly frighten me.

A—Floating specks are not serious. They are always imagined and never seen.

Q—(a) My eyes are swollen and disfigured in the morning. (b) Although I have eight and nine hours' sleep, it does not rest me.

A—(a) The swelling of your eyes or eyelids in the morning is due to eyestrain when you are asleep. Read chapter in my book on this subject.

(b) You may be restless and sleep very poorly and strain your eyes terribly, although apparently you may be asleep for a long time.

Q—I have improved my sight by palming, but when I read for any length of time the pain returns.

A—When you read and your eyes pain you, it means that you are straining your eyes. More frequent palming may help you more continuously.

Q—Explain which "swing" is beneficial, and whether one moves the whole head or only the eyes.

A—All swings when done properly are beneficial. When done improperly they are not beneficial. It is necessary for some people to move their head in order to move their eyes and obtain a perfect swing.

Q—Is there a possibility of palming wrong? I can obtain some benefit, but later I feel strained.

A—Palming may be done properly or it may be done wrong. Read the chapter on palming in my book.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

May, 1925

### Fundamentals

1. Glasses discarded permanently.
2. Favorable conditions: Light may be bright or dim. The distance of the print from the eyes, where seen best, also varies with people.
3. Central Fixation is seeing best where you are looking.
4. Shifting: With normal sight the eyes are moving all the time. This should be practiced continuously and consciously.
5. Swinging: When the eyes move slowly or rapidly from side to side, stationary objects appear to move in the opposite direction.
6. Long Swing: Stand with the feet about one foot apart, turn the body to the right—at the same time lifting the heel of the left foot. Do not move the head or eyes\* or pay any attention to the apparent movement of stationary objects. Now place the left heel on the floor, turn the body to the left, raising the heel of the right foot. Alternate. This exercise can be practiced just before retiring at night fifty times or more. When done properly, it is a great rest and relieves pain, fatigue, and other symptoms of imperfect sight.
- \*The head and eyes do move, with the body, at the same time, in the same direction. The above sentence means to avoid moving the head, eyes in the opposite or any other direction. Keep them moving in the same direction with the body.
7. Stationary Objects Moving: By moving the head and eyes a short distance from side to side, one can imagine stationary objects to be moving. Since the normal eye is moving all the time, one should imagine all stationary objects to be moving. Never imagine that you see a stationary object stationary.
8. Palming: The closed eyes may be covered with the palm of one or both hands. The patient should rest the eyes and think of something else that is pleasant.
9. Blinking: The normal eye blinks, or closes and opens very frequently. If one does not blink, the vision always becomes worse.

Reading fine print daily or two-three times a week, improving the memory and imagination; remembering, imagining objects clear, switching, shifting, central fixation on objects at close and far distances, good posture, exercise, healthy diet, positive thoughts, emotions.

### Mental Pictures

By W. H. BATES, M.D.

THE human mind is busy as long as we are awake. We remember many things and are consciously or unconsciously shifting from one thing to another. Those things that we remember, we imagine we see. If we imagine we see a letter perfectly, continuously, it is all done easily without effort or strain. If a letter or other object is remembered or imagined imperfectly, it is not remembered continuously, it soon disappears and something else takes its place. When the memory is perfect, it can be demonstrated that no effort is made, and things remembered are imagined as mental pictures easily and continuously.

Mental pictures are very important. For example, if a patient can remember and imagine he sees a letter or other object perfectly, or as well with the eyes open as with the eyes closed, or can remember when looking at the distance a small letter as well as it can be seen at the near point, the patient has a normal eye with normal sight. All cases of near-sightedness, far-sightedness, astigmatism, presbyopia disappear momentarily more continuously, or permanently, when mental pictures are imagined more or less perfectly. It can be demonstrated that when the normal eye with normal vision imagines a mental picture of a letter perfectly, the eye remains normal with normal vision, but if the same patient remembers a small letter or other object imperfectly or imagines he sees it imperfectly, the vision becomes imperfect, a change takes place in the normal shape of the eyeball and the eye becomes imperfect—too long, too short, or of an irregular shape.

The memory of imperfect sight increases the hardness of the eyeball, which can be felt with most cases with the tips of the fingers touching the outside of the upper eyelids. In cases of glaucoma, in which the eyeball is already too hard, the memory of imperfect sight will increase the tension and lower the vision. In these cases, also, the memory of imperfect sight increases pain and produces other disagreeable symptoms. Memory of perfect sight, clear objects = the eyeball is no longer hard, the eye is in normal round shape = glaucoma is removed, vision is clear.

Long Swing

Swing,  
turn Left

Swing,  
turn right

Palming

The man enjoys flying. He imagines the outside scenery and interior of the plane clear in his mind. This relaxes his mind, body and eyes, improves memory of mental and visual pictures of objects and clarity of vision.

Eyes closed, remember imperfect sight, a object unclear, blurry while lightly touching the upper eyelid to feel the hardness of the eyeball. Hardness, tension, pain occurs, increases when unclear vision is remembered, imagined.

Negative after images: If a patient regards a white Snellen test card with black letters, closes his eyes and has a mental picture of a black card with white letters, it is called a **negative after image**. In such cases the symptoms may be modified or corrected by alternately looking at the Snellen test card for part of a minute, then closing the eyes and flashing one of the large letters for a moment, a second, or part of a second. By alternating in this way it is possible to prevent the appearance of negative after images.

To obtain perfect mental pictures requires perfect relaxation. If the patient can see at the near point a small letter o with a white center whiter than it really is, or whiter than the rest of the white card, it is usually possible to close the eyes and remember or imagine a perfect mental picture of the letter. A small percentage of my patients can remember or imagine one letter or one object as well with their eyes closed as they can see it. The perfect memory of the small letter o can be imagined at five feet, ten feet, twenty feet, or further, by practice as well as it can be seen at the near point.

In one case a child nine years old was brought to me for treatment. The patient had worn very strong glasses for near-sightedness since she was three years old. When first seen she was wearing concave 14 D. S., which improved her vision from 5/200 to 20/100. At school even with her glasses she could not read the blackboard. She was a child with an unusual memory. She could look at one letter of the ten-line of the Snellen test card, see it perfectly when held very close to her eyelashes, close her eyes and remember it as well as she could see it. With her eyes open she could remember perfectly, at first at two feet, then by practice at five feet, and finally at twenty feet. Then she said that she could imagine or saw, or imagined she saw, not only the letter that she had memorized, but also other letters with which she was not familiar.

In a second case mental pictures produced a cure in a reasonable time, about a week. The patient was a man, aged thirty-five, who was wearing concave 16 D. S. combined with a cylinder of 2 diopters in each eye, which improved his vision to one-sixth of the normal. After three months of continuous treatment with the aid of palming, swinging, and other methods, he obtained a permanent benefit. His mental pictures were poor for letters and other objects. By practice he became able to remember a small black period just as black with his eyes open as he could with his eyes closed, or as well as he could see it a few inches from his eyes. He was recommended to remember the period perfectly all day long, or at night when he was awake. In the beginning he was very much discouraged, because when he noticed any improvement in his vision he soon lost his mental picture of the period and his vision failed. To prevent the loss of the memory of the period, **he was directed to dodge or look away quickly at some other object whenever he was conscious that the memory of the black period was a benefit.** This was difficult at first, but by practice he became able to **dodge or look at some other object, when his vision was improved, and in this way retained his mental picture of the period.** He was very faithful and devoted practically all of his time to his mental picture of the period. In about a week when he walked into the office he said: "Doctor, I am cured."

I tested him at twenty feet, and he told me that he could look at the 200-line letter at the top of the card for a moment without losing the perfect memory of the black period. He also informed me that he could look at the ten-line letters and dodge them just as well without losing his period. Then I said to him: "Can you see anything of the bottom line?"

He answered: "I cannot prevent myself from seeing all the letters of the bottom line."

I tested him with different cards that he had never seen before and found that he had normal vision.

Shift on a small letter o and imagine it dark black, clear with a bright pure white center. Then repeat with the eyes closed. Shift on and remember, imagine the o clear... Open the eyes and repeat.

Shift on and remember, imagine a small black period, dark black and clear with the eyes open, then in the imagination with the eyes closed, then with eyes open again. Practice until the mind can remember, imagine the period perfect, equally well with the eyes open and when closed. See the period move, swing when shifting on it.

Then, practice this while looking at, shifting on any objects. Imagining the period relaxes the mind, eyes, improves memory, imagination and activates eye movement, shifting.

### Illusions

Some years ago a physician was treated for imperfect sight. He suffered very much from illusions. His mental pictures were very imperfect. When walking along the street he would imagine little devils dancing on the tops of some of the houses. Many of the people and other objects were multiplied. Instead of seeing one person walking toward him, he saw that same person multiplied twice, three times, six times, or more. At irregular intervals he would have an attack of total blindness. He had been to see many eye doctors and many nerve doctors. Some of them told him that he was threatened with insanity, which filled him with fear. It was difficult for me to encourage him. After examining his eyes very thoroughly and testing his field, color perception, the reaction of his eye muscles, I told him that it was possible for him to be cured. He answered me and said that he was too old, fifty years.

I answered: "Children twelve years old have been cured."

He replied: "That is too bad. I have lost my chance of recovery."

I returned to the conversation by reminding him that people eighty years old had been cured quickly.

"Too bad," he said; "I will have to wait thirty years before I am eighty and that is a long time to wait."

For nine months he visited me almost daily and devoted an hour or more to all sorts of questions. He tried, as he said, to prove that I was wrong because I claimed that all the other doctors who had treated him must have been wrong, as they failed to help him. At the end of nine months his sight had become normal and he had lost most of his imperfect mental pictures. To obtain a mental picture of a period, I had him imagine a black football with about one-quarter of it painted white. This he threw into the ocean when the tide was going out, and while the football was floating out to sea he watched it very closely until it became a mere speck of black with one part white. Then by closing his eyes for a few seconds he obtained a mental picture of the period. When he remembered a period perfectly, his mental pictures of other things also became perfect, because he found it was impossible to remember one thing perfectly and something else imperfectly at the same time.

However, he still had his attacks of temporary blindness, with complete loss of vision. Finally I got up my courage sufficiently to tell him what I believed he should do next. I argued the matter with him, and told him that the memory of perfect sight could only be accomplished easily, and although he was thoroughly convinced of this fact, it did not prevent him from straining and making an effort which was strong enough to make him blind. So one day I said to him: "Doctor, there must be something wrong with your

memory of perfect sight, because you still have your attacks of total blindness from strain. Practicing on perfect mental pictures is easy. You need a better understanding of relaxation. I suggest that you now practice consciously making your sight worse by effort. This will be more difficult for you than the memory of perfect sight, but it has this advantage, it makes more clear to you what relaxation means. If you can strain hard enough to consciously cause these attacks of blindness, you will find out much better than I can tell you how to avoid them unconsciously."

I shall always remember his look of astonishment when he said: "Good God, Doctor, you have spent many months trying to improve my sight, and now you want to make it worse; it seems too absurd, silly."

I answered him: "Why should you care how silly it is as long as you get results? After all, it is not theories which help you, but results." It took me about a week to coax him to practice making his sight worse consciously. It was a disagreeable piece of business. He did not like it, but much to my surprise when through, the practice appealed to him, until finally **he became able to consciously produce an attack of blindness** which was complete, or without any perception of light. I tried doing it myself, and although I succeeded, I felt as though all my nerves were torn to pieces.

#### Military story

When the war broke out he was one of the first physicians to enlist. After the war was over I was honored by his visiting me within an hour after he landed in New York. He told me that all through the war, with the terrible strain of things, he expected that under such adverse conditions he would have a relapse. He told me that he was very grateful for what I had done for his eyes, but had no words to express his gratitude for what I had done for his peace of mind. I was pleased to have him tell me that he had no more attacks of blindness or of other symptoms caused by the memory of imperfect mental pictures. It was interesting to hear him describe how he was able to remember mental pictures perfectly throughout all the excitement and horrors of the war. He was at the front in the midst of things and was not at all worried or unhappy.

## Stories from the Clinic

### No. 63: MENTAL PICTURES

By EMILY C. LIERMAN

SO many patients tell me when they first start treatment, that they have no mental pictures. They cannot seem to remember or visualize anything while palming. If the mind is under a strain, no amount of palming will improve the vision temporarily or permanently.

A little girl, not quite three years old, came to the clinic with her mother. The mother told us that after the child had had an attack of measles, her left eye turned in. When I held the card up close, the little girl was able to tell me which way all the E's of the Pot hooks card were pointing. The squint was not so decided either. But when I held the card five feet away from her eyes, the left eye turned in almost completely, that is to say, one could hardly see the iris. I placed her little hands over her closed eyes and told her to think of her best dollie and tell me how it was dressed. I didn't expect her to tell me very much because of her age, but the little tot surprised me. She lisped in her baby talk that her best doll had a pretty pink dress, and that her shoes were black and had straps on just like her own shoes. Her mother held her as she stood on top of a table, for she was very tiny, and when she looked at the test card five feet away, her left eye remained straight temporarily, while she read 5/30 without a mistake. Her mental picture of the doll was perfect. Describing the shoes and dress helped.

At one time I had four boys under treatment at the same time. They were between the ages of nine and twelve, and all were near-sighted. They stood in a row and while palming I talked about baseball. I described the ball, and they described to me just how the ball field was arranged. After I had tested each one in turn and improved their vision, they were encouraged to palm more. Their mental pictures were—first and second base, a home run, seventh inning, etc. The four boys obtained normal sight in less than two hours that day. Two of them had 10/50 before treatment and improved to 10/10. The other two had 10/40 and 10/30 before treatment and improved to 15/10.

A young mother came to be treated for **headaches**. Ever since she could remember, she had suffered severe pain in the back of her head and eyes. Glasses were put on her when she was a small child, but they did not relieve her pain. One of her neighbors where she lived, told her how Dr. Bates had relieved her of eyestrain, so she came with a ray of hope. Palming did not give her any relief at first, and always when she came she had an attack of hysteria. When I was able to quiet her, I asked her about her children. She had two girls and a little baby boy. While we were talking she was palming. I noticed the corners of her mouth were drooped, and as she talked she had no control of her tears. Poor little mother. I had a strong desire to place my arms about her. When I discovered that her baby boy was much loved in her family, I questioned her about him.

I said: "Tell me the color of baby's eyes. I love little boys. Describe him to me."

A smile was noticeable as she answered: "His eyes are brown and his hair is blond; and you ought to see the two dimples he has when he smiles. I must not forget to tell you that he has two teeth, and when he smiles you just have to smile with him." I watched her as she explained all of this. There were no drooping corners to her mouth, but a smile was there all the time. Before I had time to tell her to remove her hands from her eyes, she did so herself. With a great sigh of relief she looked at me and said: "I have no pain just now. I feel so good I want to laugh and sing." A mental picture of her baby boy, remembering and explaining all about him was a relaxation, a benefit to her. She came more than six months to the clinic for treatment before she obtained normal vision permanently. She had a high degree of myopia when she first came, and her vision was 10/200 with both eyes.

During the first few weeks of treatment her pain would return, but each time it was less severe. When she became able by herself to obtain mental pictures, her pain would disappear and her vision would improve. At times when her mental pictures were imperfect her vision was lowered, and this always caused an attack of hysteria. Later her vision steadily improved, her pain disappeared and toward the end of six months she obtained normal sight, 10/10.

During the six months of her treatment she had to be encouraged very often by her husband or sister, to palm every day. The swing of her body from side to side, while blinking and remembering something pleasant, always helped her pain. To take care of her children and do her household duties was quite enough for any woman, but she made time to practice and she was well repaid.

## Military

After the World War was over, many of our boys on their return from France came to us for treatment of their eyes. I treated one of them who was gassed. His mind was very clear and he told me some interesting things that happened over there. I noticed, however, when he related something unpleasant or horrifying, that he stared and the sclera or white parts of both his eyes became bloodshot. His vision was normal both for the distance and the near point when he did not stare or become excited. He said the only thing that kept him from going insane while he was at the front, was that his little son, who was born after he arrived in France, was waiting for his return. He saw his pal shot to pieces almost by his side. His mental pictures were not pleasant ones, but when a photograph of his wife and baby arrived, he carried that picture with him all the time.

I showed him how to palm and told him how necessary it was to think only of pleasant things while palming. He told me many things about his little boy, and how proud he was of him. I kept him busy talking while he palmed for a half hour, and then I asked him to remove his hands from his eyes. His eyes were no longer bloodshot. The sclera was as white and clear as my own eyes. I told him to return for more treatment, deciding to use the sun-glass if necessary, the next time he came. He said if his mental pictures did not help in his home treatment, he would surely return. I never saw him again.

## Announcements

Readers of "Better Eyesight" will be pleased to hear that Dr. Bates has returned to the office and has resumed his practice. His arm continues to improve and we trust that in a short time he will be permitted to remove the plaster cast. His physician is satisfied with his progress and believes the operation was very successful.

Dr. Bates has requested us to thank our subscribers for their kindness and good wishes during his illness.

## PAPER TEST CARDS DISCONTINUED

Due to the fact that the cardboard Snellen test cards have proved three-fold more practical and durable than the paper cards, the sale of these latter has been discontinued. While the paper cards were a little less expensive, they were too fragile to stand the great handling that our test cards usually receive. We believe that the fifty cent cardboard cards will prove more satisfactory and economical in the end.

## USE THE QUESTION AND ANSWER COLUMN

It is not necessary to be a League Member or a patient of Dr. Bates to write to us for information or assistance. If any part of Dr. Bates' Method is not clear, we will be pleased to answer your inquiries through the Question and Answer column. If a personal answer is desired, kindly enclose a two cent stamp.

## PERFECT SIGHT

If you learn the fundamental principles of perfect sight and will consciously keep them in mind your defective vision will disappear. The following discoveries were made by Dr. Bates and his method is based on them. With it he has cured so-called incurable cases:

1. Many blind people are curable.
2. All errors of refraction are functional, therefore curable.
3. All defective vision is due to strain in some form.
4. Strain is relieved by relaxation.

You can demonstrate to your own satisfaction that strain lowers the vision. When you stare, you strain. Look steadily at one object for five seconds or longer. What happens? The object blurs and finally disappears. Also, your eyes are made uncomfortable by this experiment. When you rest your eyes for a few moments the vision is improved and the discomfort relieved.

Have some one with perfect sight demonstrate the fundamental principles contained in Dr. Bates' book, "Perfect Sight Without Glasses." If the suggestions and instructions are carried out, and glasses discarded, it is possible to improve the vision without personally consulting a physician.

"Perfect Sight Without Glasses" will be sent C. O. D. on five days' approval. Price, \$3.00.

## May Fairies

By GEORGE M. GUILD

THE merry month of May is expected to be just as full of joy and happiness to the children and grown-ups this year as it has been in other years. The children start the month with a big May Day celebration.

With so much fun going on we know that the fairies are there to keep everybody smiling. The good children in their hearts know they see the fairies and enjoy them, while the bad children do not see or even hear them. Someone has said that the fairies can turn into all kinds of flowers and in this way escape observation. But you can detect them because if you watch them closely, you can see them blink their eyes. Fairies always have perfect sight and to keep it they have to blink or close their eyes frequently in order to avoid the stare. You see, there are some people who have perfect eyes and, strange to say, their eyes are not conspicuous, and they do not know that they have eyes. Although their eyes are all the time moving, the movement is so short that it is not noticeable. It is a habit which they have, of which they are not conscious, but people who have poor sight are all the time staring and straining in order to see. It is not true that it requires an effort to see. On the contrary, it does require a great deal of hard work, much effort, much strain, in order to fail to see. One nice thing about the fairies is that you never see them staring at you or straining their eyes. No one ever saw a fairy wearing glasses.

Fairies have perfect eyesight. They shift, move their eyes and blink, looking at objects that interest them.

Many people ask the question, "Do fairies really exist?" A great many people believe that there are fairies, even although they themselves may not have seen any. An eminent scientific man told me that at one time he took some photographs of a flower bed covered with many flowers. He showed these photographs to some children, and right away some of them exclaimed: "Oh! See the fairies!" Neither he nor any of his friends could see any fairies among the flowers.

A man once told me that when he was a child he could remember seeing fairies, many fairies, all dancing together on the grass in the woods; but as he grew older his ability to see the fairies became less. He said that when his wife was cured of imperfect sight, she became able to see the fairies when before her cure she had never been able to see a fairy. From what is known of fairies, it seems that they can, if they wish it, become visible to anyone whom they desire to see them.

Children who have seen fairies have told me that when they saw a fairy and smiled, their sight became unusually good; but if they were disappointed in any way, the fairies at once disappeared. So when you want to see a fairy, be sure to smile. Think of all sorts of pleasant things and thoroughly believe that fairies exist. Children who doubt the existence of fairies never see them.

For some reason or other, the month of May is the best month in the year to see fairies. Most of them have rested all winter long and when the sun comes out and the flowers begin to bloom, the fairies wake up and start to have a good time. I believe that most children like to have a good time, too, just as the fairies do. When a child learns the games that the fairies play, learns to dance like the fairies dance, learns to laugh and sing like the fairies do, that child is very, fortunate, indeed. Those children who have seen fairies have told me how they dance around in a ring until they are tired, and then they go and sit on a toadstool and rest. To dance like the fairies dance is a cure for headaches. It is wonderful how long fairies can dance without getting tired. They must do it very easily and without an effort. Fairies have wonderful voices for singing, and you can hear them a very long distance away. They have wonderful eyes for seeing, and can recognize their friends from afar. They have wonderful hearts for loving which explains why they are so popular with children.

Dancing, Singing improves movement, balance, coordination, eye movement, relaxation, aligns the bones of the skull, neck vertebrae, improves circulation in the neck, head, eyes, ears and improves the clarity of vision.

Remembering, imagining the story, characters, objects, emotions you are singing about improves the memory, imagination, relaxation and clarity of vision.

Singing, dancing improves energy flow in the body.

## Glasses Retard Progress

By E. T. FISHER, M.S.M.D.

THIS patient, a man aged 53, had worn glasses thirteen years for astigmatism. Four years ago his vision became decidedly worse and had been steadily decreasing. Though his glasses had been changed repeatedly by competent ophthalmologists, his vision for distance was not improved to any appreciable degree.

His vision with glasses was 10/70 and the letters were gray and blurred. The diamond type appeared very indistinct, but he was able to read a few words in a very bright light.

Without glasses his vision was 10/200 with both eyes and with each eye separately. The diamond type seemed to be a solid gray blur. The smallest letters that he could read were those of the 30 line and he could distinguish them only when the card was held one foot from his eyes.

First I explained about blinking. I had not seen him blink once since he entered the office. As a child he was taught never to blink while conversing with anyone because it was very impolite, so he had always prevented, as much as possible, any movement of the eyelids. In this way he had acquired the habit of staring. Blinking seemed to require a great effort, but by closing his eyes for a few minutes at a time and then by gradually shortening this period he was soon able to blink easily.

His imagination and memory were very poor, but he could remember the ocean perfectly. When a child he had spent many summers at the seashore and had often sat for hours watching the waves. So I suggested that while palming he imagine himself sitting on a shore watching the waves as he had done in his childhood.

After palming 30 minutes in this way I asked him to glance at the test card and then close his eyes immediately. He saw the R in 10/100 but it disappeared before he could close his eyes.

I then held the card where he was able to see the O in the 50 line, but he could not remember it. I suggested that he imagine the O floating out into the ocean, becoming gradually smaller and smaller. After looking at the O again, he closed his eyes and imagined that it was floating away. Then he looked at the test card which was ten feet away and read both letters in the 100 line and they appeared much blacker.

The diamond type now appeared as white and black lines instead of the solid gray.

Four days later I saw him again. His vision had not improved. Before I had an opportunity to question him he said: "I know why I have not improved more. It is because I have worn my glasses about an hour a day. Each time after wearing them my sight is just as bad as it was the first time I took them off four days ago."

I had very carefully explained about not wearing his glasses, but he thought I had attributed undue importance to this phase, therefore he had not mentioned that it was absolutely necessary for him to wear them about an hour a day. As the glasses affected his vision so unfavorably and caused the loss of all that he had previously gained, it seemed doubtful that he would ever improve to any great extent as long as he continued to wear them. On days when he did not use glasses, as Sundays and holidays, his improvement was more marked and then, after wearing them, he did not lose quite all he had previously gained; but in this way his progress was exceedingly slow.

+ He practiced about three hours a day, with the diamond type, palming and sitting in the sun with his eyelids closed. In practicing with the diamond type he derived the most benefit from sitting in the sun and slowly moving the card from side to side, glancing at it casually from time to time and closing his eyes frequently.

+ In this way he first became able to see the white spaces between the lines very white, then the spaces between the words and finally, in flashes, he could distinguish words.

His progress was, without doubt, greatly retarded by his use of glasses, but now, after ten months, he is able to read the diamond type in the sun, and 10/30 on the test card. He is seeing objects at a distance that he had not seen for four years even with his glasses.

Palm and remember something perfect, that is easy, pleasant to remember. Sitting at the beach, watching the waves, sky, sand, seashells. Shift on clear objects in the mind.

## Report of the League Meeting

By MABEL A. YOUNG, *Secretary*

THE April meeting of the Better Eyesight League was held at 383 Madison Avenue, Tuesday evening, April 7th. The President, Miss May Secor, presided. Miss Secor welcomed new members and visitors to the League. She stated that as the body must be regarded as a whole of which the eye is a part, it is planned to have speakers from the outside tell of conditions in other parts of the body which may link up with trouble in the eyes.

Dr. Percival Sprinz was the speaker of the evening. Dr. Sprinz is attending oral surgeon in the Hospital for Joint Diseases, and head of the oral clinic. He is a believer in the Bates Method and a recent member of the League. Dr. Sprinz's talk was very interesting and threw light on many phases of oral infection.

## LEAGUE ANNOUNCEMENT

The meetings of the Better Eyesight League are held at 383 Madison Avenue, on the first Tuesday of each month, at eight o'clock in the evening.

The next meeting will be held on Tuesday, May 5th. At that time a practical demonstration of the Bates Method will be given by the officers of the League. One object of the League is to disseminate the knowledge of the scientific cure and prevention of imperfect sight, without the use of glasses. The president therefore requests that each member invite to this meeting at least one person who suffers from eyestrain.

## Questions and Answers

Q—Dr. Bates says that in reading fine print one should look between the lines. Is this not contrary to the principles of Central Fixation? To see the print best, should one not look directly at it?

A—One can look between the lines and shift to the black letters with Central Fixation.

Modern teachers say to look directly at the print, read through the center of the words or just let the eyes shift about on the letters, words as the eyes move along the sentence. Blink! Breathe abdominally, relax, look to the distance occasionally.

When vision is very blurry: looking at, imagining the white spaces between the sentences and the thin white line under the sentence perfect, bright, glowing white with the eyes open, closed, open improves the memory, imagination, relaxation and then the blackness, clarity of the letters. Then, the person looks directly at the letters to read.

Do not look at the white spaces when reading. Use central fixation - Look directly at the words.

Q—If type can be seen more distinctly with the eyes partly closed, is it advisable to read that way? (Squinting)

A—No, it is not advisable to read that way because it is a strain, and alters the shape of the eyeball.

Q—Should children read microscopic print?

A—Yes, the more the better. Reading microscopic print is a benefit to the eyes of both children and adults.

Q—Can the eyes be harmed by using the burning glass or sun treatment?

ANSWER—No, the eyes cannot be harmed by using the burning glass or by sun treatment.

(If done properly. See other articles:

Q—I have attained normal vision, but after reading for a while, my eyes feel strained. Would you still consider I had normal sight?

ANSWER—If your eyes feel strained you are not reading with normal vision.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

June, 1925

Perfect sight

If you learn the fundamental principles of perfect sight and will consciously keep them in mind your defective vision will disappear. The following discoveries were made by Dr. Bates and his method is based on them. With it he has cured so-called incurable cases;

1. Many blind people are curable.
2. All errors of refraction are functional, therefore curable.
3. All defective vision is due to strain in some form.
4. Strain is relieved by relaxation.

You can demonstrate to your own satisfaction that strain lowers the vision.

When you stare, you strain. Look fixedly at one object for five seconds or longer. What happens? The object blurs and finally disappears. Also, your eyes are made uncomfortable by this experiment. When you rest your eyes for a few moments the vision is improved and the discomfort relieved.

Have someone with perfect sight demonstrate the fundamental principles contained in Dr. Bates' book, "Perfect Sight Without Glasses." (Original book is: The Cure Of Imperfect Sight By Treatment Without Glasses) If the suggestions and instructions are carried out, and glasses discarded, it is possible to improve the vision without personally consulting a physician.

"Perfect Sight Without Glasses" will be sent C.O.D. on five days' approval. \$Price, \$5.00.

Central Fixation Publishing Company  
383 Madison Avenue, New York City

### Alternate

It has always been demonstrated that the continuous memory, imagination, or vision of one thing for any length of time is impossible. To see one letter of the Snellen test card continuously, it is necessary to shift from one part of the letter to another. By alternately moving the eyes from one side of the letter to the other, it is possible to imagine the letter to be moving in the opposite direction to the movement of the eyes. This movement of the letter is called a swing. When it is slow, easy, short, about one-quarter of an inch or less, maximum vision is obtained which continues as long as the swing continues.

As long as we are awake, we are thinking, remembering, or imagining mental pictures, and are comfortable. To go around blind requires a distinct effort which is a strain on all the nerves and is always uncomfortable. The normal mind alternates its attention from one mental picture to another, which is a relaxation or rest. The memory, or imagination, is best when one thing is imagined better than all other things, Central Fixation, but constant shifting is necessary to maintain Central Fixation.

One of the best methods to improve the vision is to regard a letter of the Snellen test card with the eyes open, then close the eyes and remember or imagine the letter better for about ten seconds, open the eyes and regard the letter while testing the imagination of the letter for a moment. **By alternately regarding the letter with eyes open and closed, the imagination of the letter improves in flashes. By continuing to alternate the flashes improve and last longer until the vision becomes continuously improved.**

Always shift part to part on the letter when the eyes are open and in the imagination when the eyes are closed.

Shift on the E-  
left and right, (dot  
to dot) and see it  
move 'swing' in  
the opposite  
direction the eyes  
shift, move to.  
Shifting keeps  
the memory,  
mental image of  
the letter perfect  
and vision clear.

### OLD AGE SIGHT

By W. H. Bates, M.D.

When most people with normal eyes arrive at the age of forty and upwards, they usually have difficulty in reading books or newspapers, although their sight for distance may be normal. At the age of fifty or upwards, such persons become less able to read at the near point or find it impossible to read even headlines of a newspaper clearly or distinctly. This condition has been called old-age sight, although it could be defined more accurately as the imperfect sight of middle age. The medical term for this form of imperfect sight is presbyopia. While imperfect sight occurs quite commonly in middle age, it does occur in individuals under thirty years of age and more rarely in children. There are people, however, who even at the age of **eighty or ninety are able to read just as well as when they were younger.**

The cause of presbyopia is said to be due to the hardening of the crystalline lens of the eye to such an extent that the focus of the eye cannot be brought to a near point on account of the inability of the hard lens to change its shape. Almost every eye specialist believes this theory. In my book "Perfect Sight Without Glasses" I have described the evidence which proves that the theory is wrong.

At one time I was unable to read without glasses. After I found that the lens was not a factor in accommodation, I realized that presbyopia might be cured in some cases. Then, having cured my own eyes, I felt that the old theory of the cause of presbyopia was wrong. Since that time so many patients who were unable to read without glasses have recovered that I feel most, if not all, can be cured. In my experience I have never met with a case of presbyopia which could not be temporarily benefited.

In the treatment of presbyopia most persons experience a decidedly uncomfortable feeling in their eyes when they look at fine print so close that they fail to read it. The more they try to see, the worse it becomes and the more uncomfortable do their eyes feel.

### Presbyopia Treatments

+By closing their eyes and resting them, their vision becomes better immediately after the eyes are opened, but only for a short time.

+It can be demonstrated that by staring at one letter or a part of one letter, while trying to see it perfectly, the vision always becomes worse.

+If the patient alternately closes the eyes and opens them, blinking, the vision may be improved.

+One can look at the white spaces between the lines and imagine them whiter than they really are, whiter than the margin of the card. When this is accomplished, the black letters become blacker and may be read without any effort, easily, continuously, without fatigue.

+Moving the head one-quarter of an inch or less from side to side, while looking at the white spaces, is also a benefit in many cases.

+In others, holding the head still and moving the page of fine print from side to side a short distance, may improve the

ability to read when the movement of the head may fail. Keep the head, neck relaxed and allow some movement with the eyes.

+Many people can read the newspaper when they hold it two feet from their eyes, although they are not able to read it at twelve inches or nearer. In such cases reading the large letters at two feet and improving the vision at this distance by alternately resting the eyes, enables the patient to gradually shorten the distance from the eyes until it can be read at twelve inches, later at six inches or nearer.

Some years ago a woman, **eighty-seven years old was treated for presbyopia**. The eyestrain was so great that she had been unable to obtain glasses which were satisfactory. There was a history of attacks of **hemorrhage in various parts of the retina, including the region of the center of sight or the macula**. At this time, however, the hemorrhages had all disappeared, and the retina was normal.

She was very much worried about her eyes and had a lot to say. Never in my life have I heard anyone talk so rapidly and say so much in so short a time. She repeated herself over and over again, and the constant idea that she tried to emphasize was that she was blind and that no one could give her any relief. It was difficult for me to persuade her to listen to me at first. I had to wait until she stopped for breath and then I handed her some diamond type, which I asked her to read. She very promptly told me that it was impossible, that the print was too small, and that when she tried to read it she suffered from pain, headache, and discomfort.

When my second chance came to speak, I asked her to imagine the white spaces between the lines to be perfectly white. She at once told me that that would not help her, that she could put all the white between the lines that I desired and that she was confident it would not be of any use, although she claimed to have a wonderful imagination. It seemed as though I heard two voices at the same time. One was constantly repeating that it was impossible to read such fine print, while the other voice was reading it at the same time. The audience which had collected around her, relatives, friends and servants, were thrilled, and it seemed everybody was trying to say something, to offer suggestions, and to give advice. Before we could stop her, this elderly woman read the whole card as rapidly as any one could have read it who had normal vision. When she had finished reading, and while she was wondering how she came to do it, I asked her for an explanation. She answered:

"When you asked me to imagine the white spaces between the lines to be perfectly white, I at once recalled white paint. With the help of my imagination I painted these white spaces with this white paint, and when I did that I was able to read."

While it is sometimes very difficult to cure presbyopia, it is, fortunately, very easy to prevent it. Oliver Wendell Holmes told us how to do it in "The Autocrat of the Breakfast Table," and it is astonishing, not only that no attention whatever was paid to his advice, but that we are continually warned against the very course which was found so beneficial in the case he records:

"There is now living in New York State," he says, "an **old gentleman** who, perceiving his sight to fail, immediately took to exercising it on the **finest print**, and in this way fairly bullied Nature out of her foolish habit of taking liberties at the age of forty-five or thereabouts. And now this old gentleman performs the most extraordinary feats with his pen, showing that his eyes must be a pair of microscopes. I should be afraid to say how much he writes in the compass of a half-dime, whether the Psalms of the Gospels, or the Psalms and the Gospels, I won't be positive."

Persons whose sight is beginning to fail at the near-point, or who are approaching the presbyopic age, should imitate the example of this remarkable old gentleman. Get a specimen of diamond type, and read it every day in an artificial light, bringing it closer and closer to the eye till it can be read at six inches or less. Or get a specimen of type reduced by photography until it is much smaller than diamond type, and do the same. You will thus escape, not only the necessity of wearing glasses for reading and near work, but all of those eye troubles which now so often darken the later years of life.

Shift on letters on the close fine print card, then: shift on objects through a open window - a distant sign, house, trees, mountains... Repeat.

## STORIES FROM THE CLINIC

No. 64: by Emily C. Llerman

ALBERT

Since we have had our private clinic here at the office, the charity patients come mostly from physicians. Others are sent by ministers of all churches.

Albert, aged sixteen, was sent to us by a dentist's assistant who told me of his pitiable condition. His first visit was on December 6, 1924. Albert's sister, who is devoted to him, was present, being anxious to know if we could help him. When he appeared he was wearing a black patch over his left eye because the light troubled him and he suffered intense pain. With the test card the vision of his right eye was normal, or 10/10, but the **left eye had only light perception**. This is a copy of his prescription for glasses, which he had worn for some time:

R, 0.50 D C 90  
L, 2.00 D C 90

Dr. Bates examined him with the ophthalmoscope and found Keratitis, or inflammation of the front of the eyeball of the left eye. The right eye was normal. While the examination was going on, Albert's sister was weeping. She tried very hard to conceal her tears but in vain. They had been to other doctors and were told that Albert would always have to wear glasses to save the right eye; nothing more could be done for the left eye. The last oculist they consulted said the **left eye had cataract** and as there was no sight, there was no use to operate. What a shock it was to his family!

I placed Albert in the sun and focused the sunglass on his closed eyelid. Then I raised the upper lid and quickly focused the **strong light of the sun on the white part of the eye as he looked down**. Immediately he called out to his sister: "I see the light. I can see a sort of web inside of my eye when the light is focused on it." This made me very happy indeed. I knew then that Albert could be benefited. His sister was overcome. While the tears flowed down her cheeks she said: "If you can only save that eye, there is nothing in the world I would not do for him. Mother and I will take care of him. He need never work again. I can earn enough money for both of us and he can spend all his time taking care of his eye. He must not go blind." The girl was hysterical, of course, but she meant every word she said. She loved her brother. At her age other girls are usually planning a future for themselves, but she was willing to sacrifice herself, so that her brother would not go blind. That is love, indeed.

When we started treatment, Albert became enthusiastic and palmed his eyes for more than a half-hour. He was told to think of **pleasant things while palming**. Being a perfectly normal boy, he could easily think of such sports as baseball and other outdoor games. He liked to think of the movies and could imagine scenes from the picture called "The Covered Wagon."

One could hear a pin drop when Albert first **looked at the test card with his left eye**, still keeping the right one covered. The test card was placed ten feet from his eyes and, while **swinging his body from side to side**, he **flashed the large C** on the top of the card. I was careful not to have him strain to see more, so he was told to sit comfortably and palm again.

He was with me over two hours that day and I improved his left eye to 10/100 by alternately **palming and swinging**, and also **blinking**. When we first removed the black patch, the sclera or white part of his **left eye was bloodshot**. It looked very much as though blood was ready to pour from it at any moment. There was also a considerable **watering of the eye** when it was first exposed to the light. The **sun treatment instantly stopped this**.

Before Albert left us on the first day, Dr. Bates asked me if I had the time to treat him every day. Doctor said his trouble was so serious that unless we could see him very often he was not so sure that Albert would be cured. I was glad to give the time and I have been repaid. Our dear boy is almost cured. Don't let anyone tell me that prayer does not help. I prayed earnestly every night for Albert and I know that without God's help I could not have accomplished what I did. Albert believes that, too, for he helped me in that way.

Every day that we had sunshine he improved a little with the test card. On January 17th, 1925, all the redness of the sclera had entirely disappeared. Then his visits were less frequent. I told him to come once a week instead of daily. But Albert practiced at home every day for hours at a time. The condition of his eye steadily improved and by the end of February, 1925, the vision of the left eye was almost normal.

I am proud of Albert for another reason. He would not allow his sister to support him. He asked me if shoveling snow would make his eye worse again. I said no, as shoveling snow would be practicing the swing, and the exercise would be a benefit.

Then he said, "Please pray for snow. I want to work." Again our prayers were answered. That very night we had a big snow storm, and when Albert came the next day, he told me:

"I stood in line with my shovel and stretched myself as much as possible to look big. I got a job all right, and I will earn \$5.00 per day while the snow lasts." We had one snow-storm after another and Albert had much to do.

I believe Albert's case was most remarkable because he did not at any time suffer a relapse. I believe, also, that the sun was the main factor in the relief of his trouble. I cannot understand why so many eye specialists shield the eyes of a patient from the sun. Bandaging them not only frightens the patient, but makes him very uncomfortable. It is true, that when some patients first learn

Palm and remember, imagine something easy, pleasant: The boy enjoys remembering a movie; The covered wagon. Sees objects in the mind, clear, in color, motion/action.

Palming, then read the chart, then palm, read the chart... Palming keeps the eyes, mind relaxed, no effort, no strain to see = vision is clear.

Albert looking at the eyechart with the left eye. Right eye is covered with a eyepatch.

Swing the body side to side and 'flash', shift quickly, on the letters on the eyechart, see the letters clear in flashes. Avoid staring, effort to see. Relax, swing and glance easily at the letters. Practice with both eyes, then one eye at a time, then both eyes together again.

that they are to be treated with a sun-glass, they don't like to try it. But just as soon as the light is first thrown on the closed eyelids, they relax and smile and ask for more. The sun is our greatest blessing, I think.

## The Sand Man

By George M. Guild

The little boy sat on the lap of his mother in a rocking chair. His name was Freddie. He had had a long day and was very, very tired. His mother rocked him back and forth, petted him with her cool hands and quieted him with her frequent kisses. He kept telling her: "Oh, mother, my eyes hurt, my head hurts, my arms hurt, my feet hurt, I am all hurt, and I am all tired out".

While she rocked him back and forth, a little old man came into the room with a bag of sand over his shoulder, the sand man. Freddie did not see him coming and Freddie's mother did not see him coming, but when he threw a little sand into their eyes they both became very sleepy.

Freddie sat up and looked around, stretched his arms, and his big tortoise-shell glasses fell from his eyes on to the floor. Freddie jumped down to get his glasses, and then he saw the sand man pick them up from the floor and hold them behind his back where Freddie could not get them. Freddie was very indignant and scolded the sand man for taking his glasses, but the little old man smiled and said: "Do they help you to see?" Freddie answered: "No, my eyes feel all right until I put them on in the morning, and then things are blurred, and my eyes begin to pain; but the doctor said that if I did not wear them all the time, I would most surely go blind."

The sand man said to him: "would you like to go with me and talk it over with the fairies? They don't like to see little boys or babies wearing glasses."

So the little boy took the hand of the sand man and they ran, skipping and jumping around, out of the room, into the hall, down the stairs, out the front door, through the front gate, and then into the woods. There the moon was shining very brightly through the trees and lighted up a space where thousands of fairies were dancing, laughing, and joking and having a good time. Freddie was so glad to see the fairies because in his heart he knew there were fairies, but all his uncles and aunts and cousins and grown people generally laughed at him and made fun of him for believing in fairies. When the fairies saw him coming, they all ran to him and climbed up on his shoulders and the top of his head, sat on his ears, tickled him under the chin, and made him laugh and he had a good time from the very start.

The fairies had some difficulty in teaching him how to dance their way, but they finally got him to go through movements of various kinds. The one he liked best of all was to **turn his head, eyes, and his whole body as far to the right and to the left as he possibly could without trying to see the things in front of him, which move in the opposite direction.** (The Long Swing.) He never heard fairies sing, but he heard them now and he liked the sound of their voices. He tried to sing with them, but he did so poorly and his voice was so harsh that he could not keep on singing. But the fairies encouraged him, and told him how to hold his lips and his tongue, and how to breathe, and very soon he was singing just as loud and just as musically as the rest of them. This was very strange, indeed, because he sang songs that he had never heard before, that is, consciously. Of course, when he was asleep, he would dream, perhaps, of the fairies singing, but when he woke up in the morning the dreams of the fairies, like all other dreams, were usually soon forgotten.

What surprised him most of all was the fact that his eyes did not bother him. He was no longer sleepy, no longer tired; every nerve in his body was just as happy as he was. There was no pain, only a feeling of delicious joyousness that no words could describe. Not only were his eyes comfortable, free from pain and fatigue, but he was able to see the fairies, the trees, the flowers, the birds, and the toadstools where the fairies sat to rest. It seemed to him that he could see through the trees, that he could see through the ground down into the other side of the earth where China was. He felt as though he could see the Chinese fairies almost as well as he could see the fairies that surrounded him. His eyes never kept still, they were moving in all directions, and the more they moved the better they felt. When his eyes moved in one direction, it seemed as though his hands and feet moved in the other direction, but one could not catch the other. The movement of his eyes was all the time missing the movement of his toes. They seemed like two railroad trains on parallel tracks, which pass each other going in the opposite direction at full speed. (When moving the eyes, head together, same direction, while the body is kept stationary; the body appears to move in the opposite direction that the eyes, head move to.)

He noticed that the fairies were moving in the same direction that his body was moving; the sand man, the trees, the grass, everything was moving with his body, opposite to the movement of his eyes. It seemed a very queer thing to him. The queerest thing about it was that for the first time in his life he felt his eyes were rested, although they were moving, and that for the first time in his life, also, his body, his nerves were at rest although they were, as he thought or imagined, constantly moving.

The next morning when his mother came to awaken him, she found him looking over toward the trees and smiling. Every once in a while he would laugh out loud, as loud as he could scream. His mother was worried and she said to him: "What is the trouble; why are you up so early? Why are you laughing, and why do you look over toward the trees?" Then he told her what had happened to him on the previous night when the sand man took him over to see the fairies. She smiled indulgently, as mothers will, but the next question she asked him was the most important one of all: "Where are your glasses?" Freddie looked up into the face of his mother, who leaned over and kissed him. He threw his arms around her and pressed his cheek against hers and said: "Mother, please forgive me. The sand man took them. The fairies told me how to see perfectly without glasses, so that I would have no pain and would never get tired. I want to get up early in the morning every morning and go over into the woods and play; play where the fairies played, where the fairies cured me of my poor sight."

## Report of the League Meeting

The regular monthly meeting of the Better Eyesight league was held at 383 Madison Avenue on the evening of May 5<sup>th</sup>. It was noted with regret that Miss Mabel A. young, secretary, was absent on account of illness.

The meeting was well attended and a number of new followers of the Bates Method were gained. Among these are many connected with the public schools. Great progress in the work of the League was noted.

The next meeting of the League will be held at 383 Madison Avenue on June 2<sup>nd</sup>. Subsequent meetings of the League will be held at a different address, which will be announced later.

This issue of Better Eyesight completes our 1924-1925 volume. Subscribers who wish to have their copies bound will receive the benefit of the reduced price by mailing them to us immediately. These will go to press along with our own copies. The approximate cost will be \$1.00.

### An Unfair Test

Editor's Note - Recently a high school girl wrote me of her experience with a lady school doctor who tested her sight. This may interest the parents of school children.

Dear Doctor:

I thought you might be interested in hearing about my "run in" to use a vulgar phrase, with the school physician. She is abominably prejudiced to put it mildly. She seemed extremely annoyed because you advertised with the aid of your book, "Perfect Sight Without Glasses," and your magazine "Better Eyesight," and said something about the fact that she would be put out of the medical profession if she did so. When I told Daddy, he asked if I had said that she probably deserved to be. I failed to think of that in time, but I did tell her that was your only method of giving away your discoveries when nearly all the doctors united to boycott you. That was right, wasn't it? We would have had a very pleasant squabble then but we were interrupted and I had to have my eyes tested. This will either amuse or disgust you, according to your mood. It irritated me at first, and then I saw the funny side and disturbed the entire library by my unseemly chuckles. She, the doctor, is quite six feet tall, and very masculine in appearance. Firmly grasping me by the wrist, she lifted me bodily from the chair and dragged me to the end of the room. I couldn't rebel, for she is most unconscionably strong. She shoved me up against the wall, held my neck tightly, pointed miles away it seemed, and said "Read that card." Honestly, I couldn't see anything, I was so frightened. She helped matters by smacking a large card against one eye. At length I read three lines, and the doctor didn't wait for any more, but said, "Write it down minus three" whatever that means. Then I read with the right eye, and I went through five lines without a halt or mistake. As I paused for breath, for I had seen it all in one flash, she said "Minus one." I protested I had not finished, and re-read the lines with my left eye, up to the seventh line, but she did not change the report - probably a lapse of memory, I suppose. Thus ended our historic encounter. Today, though, I had a pleasant surprise. For the first time I saw a picture perfectly. It is one which hangs on the opposite wall, and quite suddenly it sprang toward me more clearly than anything I had ever seen before. Now I know what perfect sight is, and I'll get it again, I am sure.

### Announcements

We are publishing the following names to aid those who cannot consult Dr. Bates personally, but who wish to follow his method correctly. These pupils have taken his course of treatment and are qualified to help others. They are constantly in touch with Dr. Bates' work and learn immediately of his latest discoveries.

**CALIFORNIA**  
Dr. E. Simon, 1611 Centre Street, Oakland

**COLORADO**  
Dr. H. F. Fisher, 24th Bldg., Denver  
Dr. M. W. MacKinnon, 484 Empire Bldg., Denver

**FLORIDA**  
Dr. M. S. Berry, 1008 Morgan Bldg., Tampa  
Dr. E. M. Jones, 676 First Avenue, N. S. Petersburg

**GEORGIA**  
Mrs. E. S. Butterfield, D. O., 102 East 9th Street, Atlanta

**ILLINOIS**  
Dr. E. T. Fisher, 29 East Madison Street, Chicago  
Miss Elizabeth D. Hanson, 308 N. Prospect Avenue, Park Ridge

**MASSACHUSETTS**  
Mrs. F. E. Low, Danvers

**MINNESOTA**  
Miss E. Mitchell, 506 First Avenue, St. Cloud  
Mrs. W. W. Moran, 1635 West 25th Street, Minneapolis

**MISSOURI**  
Dr. H. J. Gale, Kirksville

**NEW JERSEY**  
Dr. M. E. Gore, 51 Main Street, Orange

Dr. G. W. Renda, 517 Main Street, East Orange  
Miss Mildred Shepard, 30 Main Street, East Orange  
Dr. J. M. Winters, 8 Lombardy Street, Newark  
Mrs. A. J. Reed, East Orange (away for summer)  
J. L. MacKinnon, D.C., 200 Park Street, Kingston

**NEW YORK CITY**  
Dr. C. E. Ashera, 6 West 51st Street  
Miss May Seaton, 321 West 122nd Street  
Dr. E. Arnes, 230 West 106th Street  
Dr. L. Stanton, 49 West 57th Street  
Miss Anna Wimmer, 220 West 42nd Street, Room 1204, Tuesday and Thursday, 6 to 7.

**BROOKLYN**  
Miss E. Hurty, 177 Woodruff Avenue

**OREGON**  
Dr. Clara Ingham, 506 Alamy Bldg., Portland

**PENNSYLVANIA**  
Dr. E. G. Conch, 204 Empire Bldg., Philadelphia

**VERMONT**  
Mrs. L. J. Hathaway, Middlebury

## Suggestions to Patients

By Emily C. Lierman

- 1 - Palm in the morning while in bed.
- 2 - Take sun treatment for twenty minutes or longer every day.
- 3 - Mentally or physically, keep up that pendulum-like motion.  
(Long Swing and Sway)
- 4 - After sitting in the sun, hold the small card and flash the white spaces.
- 5 - What you do not see immediately, do not worry about.
- 6 - While practicing with the Seven Truths of Normal sight, always move the card slowly from side to side as you hold it six or eight inches from your eyes.
- 7 - To induce sleep when suffering from headache or nervous strain, close your eyes, remember the small F or T of the ten line of the test card and imagine it is moving slightly, about one-quarter of an inch, either up and down or to the left and right. (Shift point to point (small part to small part) on the letter in the mind.)
- 8 - There is a right way and a wrong way to blink the eyes while practicing. Children like to hold up their two hands about ten or twelve inches apart, looking first at one hand and then at the other. In this way one blinks when looking at the right hand and again when looking at the left hand. The head should turn in the same direction with the eyes.
- 9 - Nearsighted patients sometimes get along faster in the cure of their eyes by using two similar test cards at the same time while practicing. One card is held in the hand while the other is five or ten feet away. The patient looks at a letter up close and imagines he sees the same letter on the distant card. Then the patient closes his eyes and imagines that letter perfectly. Having seen it perfectly up close, he becomes able by practice to see it just as well on the distant card.

Shifting, Blinking, Central Fixation

Look at, shift on the left and right hands, one hand at a time. Move the eyes and head together, left and right. Notice that the eyes blink automatically as the eyes move, shift from one hand to the other hand. Notice that the hand the eyes are looking directly at is in the center of the visual field and is clearest - central fixation. The other hand is in the peripheral field and is less clear.

## A case Report

(Report of a man, 63 years old, who has worn glasses for a great many years. He improved his own vision merely by following directions. Others can do the same.)

I will be **63 years old** in July and have not worn lenses since reading "Perfect Sight Without Glasses"; it will be two years the latter part of next July.

I have had monocular vision all my life, congenital convergent squint of left eye producing what has always been called "partial blindness from disuse." I could always see parts of everything but nothing distinctly; enough to get around if I closed my good eye, but could never see to read any printed matter with it.

At first I could not see the big "C" at any distance with the left eye. Now I can see its whole outline at about six inches and all of the letters on line ten at three or four feet.

In scanning even fine print I can now discern lines and spaces and almost distinguish the letters by holding it close up.

I should add that I have not been at all diligent nor faithful in using Dr. Bates' methods and am surprised at the results obtained by me in spite of that fact. With more devotion I am sure I will get better results.

One patient, a woman of 25 or 30, had worn **glasses seventeen years**. She was **myopic** with **astigmatism**, seeing about half the distance with the left eye as with the right. She had frequent **headaches**, could not go to the "movies" without great distress. She spent \$300 or more on glasses, had no comfort with them, and could not see well with or without them.

She was induced to buy Dr. Bates' book last March. She laid aside her glasses and began to work according to the method, wholly by herself, with most satisfactory results.

Very gratefully yours,  
Fred W. Morris, D.O.,

## QUESTIONS AND ANSWERS

### Shifting, Swings, Oppositional Movement Described

Q- When I look at an object and blink, it appears to jump with each blink. Would this be considered the short swing?

A- Yes. You unconsciously look from one side to the other of the object when blinking.

Q- Please explain the difference between the long and short swing.

A- The short swing is about the length of a letter. The long swing is the movement of a letter an inch, a foot, or more.

Q- What are the benefits of each?

A- The long swing relieves eye discomforts and helps one to obtain the short swing. The short swing improves the vision.

Q- Seeing stationary objects moving appears to me to be merely self-hypnotism. I can't do it.

A- When riding in a train the stationary telephone poles *appear* to move in the opposite direction.

Of course this is an illusion, but it is a benefit to the eyes to imagine all stationary objects moving.

Q- I heard your lecture at the Psychology Club and immediately discarded my glasses. Now I cannot see at all and am worse off.

A- You can be cured by practicing relaxation methods when you discard your glasses. You cannot be cured when you use your glasses for emergencies.

Q- You stress palming in your instructions. If I obtain poor results with this exercise should I continue?

A- No. Do that which is most helpful.

### *Catalogue of Other Publications*

#### **BETTER EYESIGHT MAGAZINE**

Back numbers may be obtained here which contain articles on the cause and cure of the following defects: Myopia, Squint, Glaucoma, Cataract, Pain, Blindness, Presbyopia and Retinitis Pigmentosa.

These articles include instructions for treatment.

#### **Bound Volumes**

Each volume contains one year's issue of twelve magazines.

Price, \$3.50.

#### **Burning Glass**

If you notice a strain on your eyes, after emerging from a building into the sunlight, you need the Burning Glass. If the light feels uncomfortable, or if you cannot look up at the sun, the burning glass will help you. Instructions are issued on request.

If you need it, send for it today. Price \$5.00.

#### **Fine Print for Relaxation**

The Bible has been reduced from 14.00 to \$2.50. Read what Dr. Bates says about fine and microscopic type, then get a Bible. This unique book measures only one by one and a half inches, and contains the Old and New Testament.

#### **The Booklet**

of fine print contains three chapters from the small Bible, together with "The Seven Types of Normal Sight" as discovered by Dr. Bates. Instructions are also printed in the front of the book. Price 15c

#### **Test Cards**

These prove invaluable in practicing Dr. Bates' method. Instructions issued. Can be used to test the eyes, follow progress, and improve sight.

99c.—75c

### **PERFECT SIGHT**

If you learn the fundamental principles of perfect sight and will consciously keep them in mind your defective vision will disappear. The following discoveries were made by Dr. Bates and his method is based on them. With it he has cured so-called incurable cases:

1. Many blind people are curable.
2. All errors of refraction are functional, therefore curable.
3. All defective vision is due to strain in some form.
4. Strain is relieved by relaxation.

You can demonstrate to your own satisfaction that strain lowers the vision. When you stare, you strain. Look fixedly at one object for five seconds or longer. What happens? The object blurs and finally disappears. Also, your eyes are made uncomfortable by this experiment. When you rest your eyes for a few moments the vision is improved and the discomfort relieved.

Have some one with perfect sight demonstrate the fundamental principles contained in Dr. Bates' book, "Perfect Sight Without Glasses." If the suggestions and instructions are carried out, and glasses discarded, it is possible to improve the vision without personally consulting a physician.

"Perfect Sight Without Glasses" will be sent C. O. D. on five days' approval. Price, \$5.00.

**Central Fixation Publishing Company**  
383 Madison Avenue, New York City

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

July, 1925

### SWAYING

It is a great help in the improving of vision to have the patient demonstrate that staring at one part of a letter at ten feet or further is a difficult thing to do for any length of time without lowering the vision and producing pain, discomfort, or fatigue. With the eyes closed it is impossible to concentrate on the memory or the imagination of a small part of one letter continuously without a temporary or more complete loss of the memory or the imagination.

When an effort is made to think of one part of a letter continuously with the eyes closed, the letter is imagined to be stationary. When the imagination shifts to the right of the letter a short distance and then to the left alternately, every time the attention is directed to the right, > the letter is always to the left, < and when the attention is directed to the left < of the letter, the letter is always to the right >. By alternating, the patient becomes able to imagine the letter is moving from side to side, and as long as the movement is maintained the patient is able to remember or imagine the letter. It can be demonstrated that to remember a letter or other object to be stationary always interferes with the perfect memory of the letter. One cannot remember, imagine, or see an object continuously unless it is moving. The movement must be slow, short, and easy.

When patients stare habitually, the eyes become more or less fixed, and are moved with great difficulty. When the patient stands and sways the whole body from side to side, it becomes easier to move the eyes in the same direction as the body moves. No matter how long the staring has been practiced, the sway at once lessens it.

 Stare at one part (dot) of the letter E. Memory, imagination of the letter is lowered, strain occurs, the letter is seen unclear.

 Shift part to part, left and right (dot to dot) on the letter E. Blink. See it appear to move opposite the movement of the eyes. Memory, imagination of the letter is perfect, the letter is seen clear. Shifting, movement relaxes the mind, body, eyes, improves memory, imagination and clarity of vision.

Natural Eyesight Improvement Astigmatism chart. Look at, shift on, see darkest black and clearest one black line at a time. Trace along a line, Shift line to line.

### ASTIGMATISM

By W. H. Bates, M.D.

The word has frightened a great many people. When a patient has astigmatism, it means that the shape of the eyeball is changed from the normal sphere to one that is lopsided. One may be near-sighted and have in addition a certain amount of astigmatism. The same is true in the far-sighted eye, which may have at the same time a certain amount of astigmatism. In most cases the front part of the eyeball, the cornea, is the part affected.

In making the diagnosis of astigmatism, the so-called astigmatic chart has been highly recommended. It has been used for more than fifty years and is still popular. The chart consists of vertical, horizontal, and oblique lines. When a patient has astigmatism; the lines running in one direction appear more distinct than the lines running in other directions. I do not consider the astigmatic chart a very good or reliable test, because many patients with no astigmatism have imagined the lines in one direction to be much plainer than the lines at right angles to them. Also, in many cases of astigmatism, all the lines may be seen with equal clearness. Another objection to the test is that when some patients with normal eyes and with no astigmatism, regard the astigmatic chart, a high degree of temporary astigmatism has been produced, which was demonstrated by other tests - retinoscope, ophthalmometer.

The instrument for the diagnosis of corneal astigmatism is called the ophthalmometer. When the normal eye was examined with its aid, the curvature of the cornea has been found to be normal in all directions. When the eye was under a strain, the curvature changed, sometimes being more convex in one meridian than in all the others, or one meridian might be flatter than the other meridians. The axis of the astigmatism produced by a strain has been observed to vary, increase or diminish, while the instrument was being used.

When the patient **remembered perfect sight, no astigmatism was manifest and the curvature of the cornea remained normal**. When a letter or other object was remembered by the patient, one part best-central fixation, **no astigmatism was produced**. When astigmatism was present, the amount was lessened or it disappeared altogether when central fixation was remembered or imagined. It can be demonstrated that no astigmatism of the cornea can be observed with the aid of the ophthalmometer when the patient is able to remember or imagine letters or other objects by central fixation.

It is also a truth that **when things are remembered or imagined to be moving with a slow, short, regular, continuous, easy swing, no astigmatism is present** when the cornea is examined with the ophthalmometer. The demonstration cannot be made by an observer who does not understand what is meant by the ocular swing.

**Rapid blinking also lessens or corrects corneal astigmatism** temporarily or more continuously when done properly. When done under a strain, astigmatism may be produced or increased. The ophthalmometer demonstrated the facts.

**Sun-gazing**, when practiced in such a way as to improve the vision, also is followed by an immediate benefit to the astigmatism, as observed by the ophthalmometer.

It has been noted that after the eyes are closed (palming) for some minutes or longer, and rested, when they are first opened, an immediate improvement in the astigmatism is manifest.

Any form of treatment which was a benefit to the vision of the patient was also a benefit to the astigmatism, as demonstrated by the ophthalmometer.

The textbooks on the eye have for many years published that most, if not all, cases of astigmatism occur at birth, or that they are congenital. It was supposed to be a permanent condition, but further study of astigmatism has shown that it may be acquired at any age. School children have been observed to acquire astigmatism at the age of eight, ten, fifteen years, or older. When the eyes were examined periodically, the astigmatism in many cases had changed. It is capable of increasing or of decreasing. It is an interesting fact that some cases do recover without treatment. This suggests the possibility of successful treatment.

**In the normal eye astigmatism can be produced by a strain to see either at the distance or at the near point**. At first it is temporary, but later may become more permanent. **Astigmatism can always be corrected by relaxation or rest**. When the imperfect sight of astigmatism can be corrected by glasses, it is called regular astigmatism, but when the vision cannot be

improved to the normal in this way, it is called irregular astigmatism.

Many scientific articles have been written on irregular astigmatism which are offered as evidence that it is incurable. The men who wrote these articles did not cure irregular astigmatism and, therefore, being authorities in the medical profession, they stated that nobody else could cure it; and, furthermore, anyone who claimed to be able to cure this form of astigmatism must be a charlatan, and should be expelled from the medical profession.

Irregular astigmatism is produced by eyestrain and relieved or cured by relaxation or rest. Most cases of **ulceration of the front part of the eyeball, the cornea, produce a scar** which is more or less opaque. Irregular astigmatism is also caused by ulceration of the cornea.

Patients who cannot stand the light, **photophobia**, suffer very much from eyestrain. These cases acquire astigmatism which is usually corrected by encouraging the patients to become accustomed to the **strong light of the sun**. Ulceration of the front part of the eye occurs quite frequently in young children who live in the tenement houses where the light is poor. Astigmatism is found after the ulcerations have healed. Irregular astigmatism has usually been cured by the sun treatment with the aid of the swing, central fixation, and the memory of perfect sight.

Advanced cases of **conical cornea** have **irregular astigmatism**, which heretofore has not been relieved by various kinds of operations, glasses, or any other form of treatment. In this disease the front part of the eyeball becomes much thinner and an opening may form with great harm to the eye. In one of my early cases conical cornea occurred in both eyes with one very much worse than the other. It reminded me that when the eyeball is elongated in nearsightedness or myopia, the bulging appears at the back part of the eyeball, which has been called Posterior Staphyloma. These cases have recovered after a long period of treatment. A temporary cure has been demonstrated with the aid of the ophthalmoscope by the memory of perfect sight. The same is true of conical cornea, which also disappears temporarily with the aid of the memory of perfect sight. These cases become worse by the memory of imperfect sight. Staring always increases the bulging and makes the vision worse.

Conical cornea with its irregular astigmatism, occurs not only in adults but, like near-sightedness, is found also in young children. For such cases the swing has been a great benefit. The mother or nurse can stand facing the child, take both hands and sway from side to side for several minutes or longer. Teaching the child to dance is also a great help. Playing games requiring movement, like running, prevents the stare or strain in most cases. It is well to remember, however, that when the child is moving more or less rapidly from one place to another, the stare is always possible. Encourage the child to look from one place to another. The old-fashioned game of "Puss in the Corner" is a great benefit to the eyes. In this game the child is constantly shifting his eyes from one place to another.

The child should enjoy the games, especially when adults join in the game. Often times a young patient will become quite boisterous and scream with excitement and pleasure. He may be as noisy as he likes. He may play, laugh, and scream and become very much excited with great benefit to the astigmatism. It is well to exclude all children who carry around with them a grouch, or who make the patient uncomfortable by teasing him.

In my office there have been times when a child made so much noise that my other patients were interested, and too often, perhaps, disturbed. Between the mother, the child, and myself, we have had quite a riot with a great deal of noise and loud laughter on the part of the child, but always the astigmatism improved. Anything that helps the child is justifiable. Don't forget that children, as a rule, enjoy themselves more when they are allowed to make a noise than when they are expected to stay quite. The kindergarten methods of teaching should be practiced. The Montessori system is also a great help in relieving irregular astigmatism from any cause, as well as conical cornea.

One of my worst cases of **irregular astigmatism** occurred in a woman, seventy-five years of age, who gave a history of ulcerations of the cornea, for a long period of years. After each attack, opacity of the cornea appeared, and with repeated attacks the opacities increased until the patient was unable to count fingers. She was recommended to sit in the sun with her eyes closed, holding her head in such a way that the sun shone directly on her closed eyelids. Most of the time while she was awake, she practiced the long and the short swing alternately. After a number of months her vision improved so that she became able to thread a needle and do some sewing. She became able to read fine print without the aid of glasses. Her vision for the Snellen test card was also materially improved.

## STORIES FROM THE CLINIC

### No. 65: Cataract

By Emily C. Lierman  
Mother Jones

A friend of mine who knows me very well, perhaps better than I do myself, asked me if I ever got tired of clinic work, do I ever tire of treating obstinate cases – those who take a long time to cure. No, indeed, I do not. The harder a case is to benefit, the better I like it. I never tire of my patients, but I get tired myself. We appreciate rest all the more when precious work like ours makes us tired.

Mothers of the clinic, that is, most of them, are restful to me. I love to treat them. To see tenderness, the loving expression come to their faces, always brings a perfect mental picture of the Madonna to my mind. When Mother Jones comes, she gives me that picture.

Her first visit was on November 1st, 1924. She brought with her a note written by her pastor. Dr. Bates had cured many of his friends, so he was sure we could do something for Mother Jones. Her age was sixty-seven and she was troubled with cataract in both eyes. Her vision became defective about four years ago. Dr. Bates' examination with the ophthalmoscope showed a red reflex in the right eye, but none in the left.

After Dr. Bates had left the room, Mother Jones began to talk. I believe as long as I live I shall always remember the sound of her voice. When I compared her with the Madonna, I was not trying to give the impression that Mother Jones is beautiful of face or form. She is of the ordinary motherly type. But the impression one receives while looking at her, listening to her tender voice, suggests something holy. She did not know of anyone who had been benefited by the Bates method, but her pastor had sent her, that was enough. She is very poor, but her son and family are taking care of her. When I told her that the only way for her to be cured was to practice faithfully every day, and to do exactly as she was told, she promised to do her part. When I tested her sight

with the test card, she read 10/70 with both eyes together. Her vision with the right eye was 10/70, but she could not see the card at all with the left eye at ten feet.

She was instructed to palm and to think of something pleasant, something easy to remember. I left her by herself for about ten minutes, and when I returned she had not stirred, and her eyes were still covered with the palms of her hands. I told her to keep her right eye covered, but to open her left eye and tell me what she could see. I held the test card five inches from her left eye, and at that distance she saw the 200 line letter C. She sighed with relief when she discovered that her left eye was not really blind, but was made so by strain and tension. In this short time the benefit she received from palming proved to her that her cataract was caused by strain.

I placed her in the sun, and while her eyes were closed, I used the sun-glass on her eyelids. I could see her relax, and she smiled as she felt the warmth of the sun's rays. I led her back to her chair and told her to open her eyes and read the test card. Her vision had improved to 10/30, reading with both eyes. She was instructed to practice ten minutes many times every day, alternately palming, blinking, and flashing letters on the test card.

Mother Jones came once a week without missing a treatment, and each time her vision improved with but two exceptions, when it remained the same as on the previous visit. On her second visit she read 10/30 after palming, and on the third treatment 10/20.

This dear mother appreciated the sunshine more than any cataract case I ever had. On dark and rainy days, she was always despondent and nervous, but the sound of her voice never changed. Once when she failed to appear for treatment, I feared she was ill, and I worried about her. I had noticed that her clothes were none too warm during the cold days, and thought perhaps that was the reason for her absence.

While I was thinking about my bank account, a letter came from a private patient who is also one of my adopted mothers. She comes from Ohio, where I have many friends. Her gratitude for the great benefit she has received from Dr. Bates prompted her to send a sum of money to be used in making my clinic family happy. Mother Jones and another poor mother with a big family, and dear old Pop, who lives in a home for the Blind, shared in the loving thoughts of my mother from the West.

Mother Jones soon returned to thank me for the gift and to explain why she had been absent. Her son had become a daddy, and both the mother and baby were doing fine. After my joy had been expressed over this great event, I produced a strange test card which she had not seen before, and placed it ten feet from her eyes. Some of our readers may doubt it, but I do believe that the little stranger from heaven had something to do with the improvement in the vision of her grandmother. She read 10/20 with her left eye.

Soon after, I was called upon to take charge of our private practice because of the illness of our dear Dr. Bates. Captain Price of London, England, who is practicing the Bates system successfully in his country, was in our office at the time and offered to help me and my wonderful assistant of the clinic, Miss Mildred Shepard. I placed Mother Jones in his care. His record showed on February 7, 1925, right vision of the white C card - 10/20, left vision - 10/20. At her second treatment by Captain Price, her right vision was 10/15, left vision 10/15, reading white letters on black card.

Some ophthalmologists would certainly appreciate this, if they would only study and practice the Bates system. What further proof is necessary to convince those of pessimistic minds, that our method of curing people without glasses is a purely scientific one?

Mother Jones is still under treatment, but it will not be long before she will enjoy normal sight. She tells everyone who will listen to her, about how much better she sees and how much better she feels, since she knows how to relax and relieve her eyestrain.

### PALMING

(Miss Elisabeth Hansen of Chicago, a teacher in the sixth grade, has done wonderful things for her pupils. She has taught them palming, which has relieved their nervousness, improved their memory and imagination, and their sight. The testimony of these children is so interesting, that we feel some of it should be published. The children not only benefited themselves, but they also benefited other children, their parents and their friends. - W.H.B.)

**Palming** is the greatest discovery I have read about. It has made me so happy. At first I could not see a thing. I spent money trying to cure my eyes, but nothing could help me. I heard of a great doctor teaching imagination and memory. So I wished for that doctor to teach me how it was to be done. My teacher knew of him and inside of a month palming four times a day, my imagination was getting better and my memory brought back the day when I was younger and I remembered the time I played with my eyes. But when I am old enough I shall travel to all parts of the world to show people how to use and take care of their eyes.

Joseph De Fiore.

I think palming is the best thing in the world, because it makes your eyesight good. I'm sure that if I keep palming all the time my brains and nerve will get better. The first time I never liked to do it, but then I got used to it and now I do it every day and every second I get. One day while I was going home I met my girlfriend. We were talking about our eyesight and I told her that my teacher teaches all the room every day. I told her that I would teach her how to do it, if she wanted to. So she took my offer and she said to me, "Come on Margaret, let's go to my house, I went and she said, "Teach me how". I taught her how to swing and palm. Her name was Marie. She thanked me very much. The next day she brought other girls I knew and I taught them the same thing.

Margaret Micalett.

Palming has done a great deal for me. I can read the smallest letters on the chart. I do much better imagination than I used to do. I have learned better English and can read better, etc. I have taught my two sisters how to palm. One of them used to get terrible headaches. And since she started to palm she is getting rid of them. I have also taught them to swing and to read the chart. Now they are doing better.

Adeline Valentine.

One day a boy friend of mine dropped a half-dollar. He was looking for it, but could not find it. Of course he had had trouble with his eyes for over a year. I walked out of my yard and asked him what he was looking for and he told me about the half-dollar. I looked on the sidewalk and found it the minute I laid my eyes on the walk. He asked me how I came to have such strong eyesight, and I told him that our teacher taught a lesson to keep eyes in good condition. He asked me to come to his house. I told him that by palming, his eyes would be better. He asked me how many times a day. I told him six times or more. Then I heard my mother

calling me. I went home. Inside of a week the boy took off his glasses, threw them in a box and told his mother he would never put them on again.

John Marshall.

Many years ago I had poor memory. I was persuaded by all nurses to wear glasses. One day my father bought me glasses. I tried in vain not to wear them, but I had to. Finally I got poorer memory and became sick. I told my father the glasses made me sick. The very minute my father broke them. My teacher taught me how to palm and swing. Soon my memory got to be good. I could see as good as any child in the room. This proves palming and swinging is good for memory and imagination.

Edward Yonan.

### THE DREAM KING

By George M. Guild

Georgie was eight years old. He had never seen the Dream King. His mother had promised to tell him all he wanted to know if for one day he did not lose his temper or cry when told to wear his large, heavy spectacles that hurt his nose and made his eyes pain.

One day he succeeded. While his mother sat in her rocking-chair she had a hard time to keep awake. Georgie spoke to her several times, but she did not hear him. While he sat there fretting, he was surprised to see a nice young man, about his own height, walk into the room, take him by the hand, and lead him away. He told him that he was taking him to see the Dream King.

Georgie jumped up and down with pleasure and laughed all the way. Pretty soon they came to Shadowland, where everything was more or less in the shadow, because the only light that Georgie could see was the light of the moon. Every once in a while the person who was conducting him would disappear and someone else would take his place. Sometimes it was a woman, and finally it was a little, old man. He told Georgie that he was the sand-man, who went around throwing sand into little boys' eyes to make them go to sleep. But he did not throw sand into Georgie's eyes. Instead, he kept him awake telling him such queer things that Georgie quite enjoyed his companionship.

Georgie was sorry to see him go when a blue fairy took his place. She led him to a large open space in a forest, where the grass was cut thin, and on which hundreds and thousands of fairies were having a good time. They were playing a very curious game. They had placed an elderly man on a throne and they crowned him with flowers. He held in his hand a short stick which they told Georgie was the wand of the Dream King. When he waved the wand, touched you, and you wished for something, your wish was granted, first in a dream and then later in reality. Immediately Georgie wished that his eyes would not hurt him any more, and that he could see perfectly without glasses.

The Dream King touched him with his wand and at once Georgie began to sway his body from side to side. His glasses fell from his face, and he found that he could see better without them than he had ever seen with them. It seemed to him as though everything were moving in the opposite direction. The trees, the fairies, and even the Dream King, were all moving in time with his movement. He remembered the faces of the boys that he had played with; he remembered his mother's face—his mother's face which was so tender, kind, and loving.

He became very much interested in what the Dream King was doing. People from various places were bringing all sorts of queer creatures to the Dream King. One fairy brought him a little duck, a few days old, which was about the ugliest duck that Georgie had ever seen. The Dream King touched it with his wand, and at once it became a beautiful swan. He saw caterpillars, ugly, sticky things. The Dream King touched them in turn with his wand, and they became beautiful moths or butterflies which flew away to where flowers were blooming. He saw children who were cripples and were unable to walk without crutches, but after the Dream King touched them with his wand, they threw away their crutches and left his presence laughing, singing, and dancing. It was astonishing to see all the animals, people and bugs who were relieved of all kinds of imperfections and obtain perfect health.

There was a beautiful fairy standing near Georgie. He spoke to her and asked her why she looked so sad. She told him that she had no soul and could never obtain one unless some mortal fell in love with her. Right away Georgie fell in love with her because she was so beautiful and nice. She threw her arms around his neck and kissed him, and thanked him for what he had done because now she had a soul and could be like real people.

Georgie was so pleased that he quickly took her to his mother. When he entered the room where he had left her, he found her still sleeping. He climbed up into her lap, threw his arms around her neck and kissed her. She woke and said: "Oh, Georgie, I had such a curious dream. For a long time I have been worried about you, because you had to wear glasses, but in my dream I imagined that the Dream King had cured you. Now that I am awake, I feel that your eyes are troubling you and that you will still have to wear awful glasses."

Georgie laughed and said: "Oh, no. I never will have to wear my glasses again, because the Dream King has cured me. Although it was only a dream, I believe it will come true when you have the fairies to help you." His mother said to him, "But you have no fairy to help you."

"Oh, yes I have," he answered, and introduced his fairy to her.

The mother looked so bewildered that he was quite sure she did not see the fairy. "Never mind, mother, I know that you do not see my fairy. I dreamed that I found her, and she is so sweet and lovable that I shall always dream, imagine, or believe that I have her. She has promised to help me keep up the swing, and to remember or imagine perfect sight all the time. I love her very much, I will always love her, and I know that I will never strain, stare, or hurt my eyes again."

### Announcements

#### Correction

Dr. J. L. MacKinnon, a student of Dr. Bates, is using his method successfully in Kingston, New York. The June issue of "Better Eyesight" removed him from Kingston, New Jersey, in error.

## Suggestions to Patients

By Emily C. Lierman

### THE USE OF THE SNELLEN TEST CARD

- 1 – Every home should have a test card.
- 2 – It is best to place the card permanently on the wall in a good light.
- 3 – Each member of the family or household should read the card every day.
- 4 – It takes only a minute to test the sight with the card. If you spend five minutes in the morning practicing with the card, it will be a great help during the day.
- 5 – Place yourself ten feet from the card and read as far as you can without effort or strain. Over each line of letters are small figures indicating the distance. Over the big C at the top is the figure 200. The big C, therefore, should be read at a distance of 200 feet.
- 6 – If you can only see to the fifth line, notice that the last letter on that line is a R. Now close your eyes, cover them with the palms of the hands and remember the R. If you will remember that the left side is straight, the right side partly curved and the bottom open, you will get a good mental picture of the R with your eyes closed. This mental picture will help you to see the letter directly underneath the R, which is a T.
- 7 – Shifting is good to stop the stare. If you stare at the letter T, you will notice that all the letters on that line begin to blur. It is beneficial to close your eyes quickly after you see the T, open them, and shift to the first figure on that line, which is a 3. Then close your eyes and remember the 3. You will become able to read all the letters on that line by closing your eyes for each letter.
- 8 – Keep a record of each test in order to note your progress from day to day.

### DARK GLASSES

Many people when they go from a dark room out into the bright sunlight are dazzled, and feel uncomfortable. If they put on dark glasses for a time, the eyes are more comfortable, and they are tempted to wear such glasses most of the time.

It is a common practice that when a patient goes to an eye doctor, and complains of the discomfort of the strong light of the sun, the doctor will recommend dark glasses, which are usually comfortable in the beginning. Later on, however, the eyes become accustomed to wearing dark glasses, and will feel uncomfortable when the light is good. They are practically in the same condition as they were when they first put them on.

**Miners, who work underground who seldom see the daylight at all, always have diseased eyes.** There are some diseases which cannot be cured without exposing the eyes to the light of the sun. No matter how strong it may be, while it may prove temporarily uncomfortable, the sun has never produced a permanent injury.

Many people purchase dark glasses along with their other vacation necessities, because they are afraid that the reflection of the sun on the water will harm their eyes. Others have found that by becoming accustomed to the strong light of the sun, their vision was materially improved, but by wearing glasses to protect their eyes, their vision always failed. The proper thing to do is to become used to the sun at all times and in all places. **The eyes need sunlight.** If they do not get it they become weak.

One of the best treatments is to focus the strong light of the sun on the white part of the eye with the aid of a burning glass (sunglass), which is kept moving from side to side to prevent the discomfort of the heat, while the patient is looking far down. In many cases treatment has accomplished in a few minutes a complete cure of sensitiveness to light.

### QUESTIONS AND ANSWERS

Q- I have understood that if glasses are not worn, the sight becomes worse.

A - After wearing glasses and then removing them, the vision is always worse than if they had never been worn.

Q- When people remove their glasses, I notice their eyes look dull and expressionless.

A- It is due to the fact that wearing glasses has increased the stare.

Q- It is said that defective vision is due to a change in the shape of the eyeball. Does a cure by the Bates Method affect the shape of the eyeball?

A- When a person is cured by the Bates Method the eyes become normal and the expression is one of relaxation or rest without any strain. When the eyes are cured, the eyeball becomes normal in shape and is neither too long nor too short.

Q - Is it better for a myopic person to suffer inconvenience by not seeing at a distance without glasses, than to have them for special occasions?

A - When a myopic person desires to be cured without glasses, it is absolutely necessary to discard glasses permanently, and never to wear them even for emergencies.

(Some Modern Natural Vision Improvement teachers allow the patient to wear reduced, weaker eyeglass lenses if necessary for driving and other activities requiring safety. Even reduced lenses block vision improvement but not as much as strong lenses.)

SCHOOL NUMBER  
**BETTER EYESIGHT**

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

August, 1925

**FEAR**

Near-sighted people have frequently been told that it is necessary for them to wear glasses constantly, to prevent their eyes from becoming worse. They are afraid that this statement may be true, and one cannot blame them for hesitating to leave their glasses off permanently.

One of my patients stated that she suffered very much from headaches. They were so severe that they made her ill, and confined her to her bed at least once a week. While wearing her glasses, she still was in pain, but was afraid, if she left them off, the headaches would become worse. By discarding her glasses, practicing **palming**, **swinging**, and the **memory of perfect sight**, her eyes and head improved immediately. When she resumed her glasses again, she at once became uncomfortable, and the pain returned. She decided to leave them off permanently, and her headaches disappeared.

Some years ago an optician consulted me about his **headaches**. When I examined his glasses, I found that they were plane window glass. He said that when he wore them his headaches were better, but his wife confided to me that this was not true. He was troubled more when he wore them. He was suffering from fear.

I saw him again a year later and learned that he had permanently discarded his glasses, at my suggestion, during all that time, and was free of headaches.

It has been a habit with me, when patients who suffer from fear of the consequences that might happen if they did not wear their glasses, to have them demonstrate the facts. When the truth is known, fear is abolished. It is very easy in most cases to teach patients some of the causes of headaches.

**SCHOOL CHILDREN**

By Dr. W. H. Bates, M.D.

The August number of "Better Eyesight" each year is devoted to the problem of the Imperfect Sight of School Children. Every year we have evidence that when most children enter school, their vision is normal. After a few years, most of them acquire imperfect sight. The average is about eighty percent (80%). Of these nearly all have acquired farsightedness and astigmatism. At the age of ten or twelve near-sightedness appears, and far-sighted children become less. It is a truth that should be emphasized, that nearly all of the cases of imperfect sight in school children are acquired after they enter school.

For more than a hundred years, eye doctors have believed that far-sightedness is congenital, or is present at birth. They did not believe that it could be acquired. A plausible explanation suggests that young children are more accustomed to using their eyes for distant vision without effort, and for this reason their distant vision is good. However, when they enter school and begin to study from books, they begin to strain at the near point. I have repeatedly published that a strain to see at the near point always produces far-sightedness, or hypermetropia. It is not many years before the distant vision becomes imperfect from the strain. Then, when the child makes an effort to see at the distance in order to correct its imperfect distant vision, near-sightedness, or myopia, is produced.

It is difficult to explain why some children strain to see at the near point or at the distance, when others do not strain at all. I have had children consciously strain and lower their vision either at the distance or at the near point, or, in other words, demonstrate that the strain does not improve their sight. They were unable to tell me why they did it. However, some children profited by their experience and told me that the reason they did not strain was because it lowered their vision. In most cases where the children became conscious that the strain lowered their vision, they told me that the reason they kept on straining was because they did not know what else to do. There are a number of teachers who have suggested to their pupils that, since strain causes imperfect sight, why not try resting the eyes, which many of them did with benefit.

However, there is a cause of eyestrain in school children which has not been sufficiently emphasized. Children and adults imitate others, consciously or unconsciously. For example, when one person yawns, many others, consciously or unconsciously, yawn also. If in a company of people a feeling of pleasure prevails, each newcomer consciously or unconsciously assumes the same state of mind; but when an objectionable person, who is disagreeable, enters the room, a general feeling of discomfort among those present is felt.

Mothers, fathers, or other relatives affect the minds and the nerves of their children or of other people's children. If one or both parents are wearing glasses for the relief of eyestrain, the children who associate with them a good deal, acquire eyestrain and their vision becomes imperfect. In one case I remember where the mother was suffering from eyestrain, accompanied by a high degree of near-sightedness in one eye. She was exceedingly nervous. Her vision was so much improved by treatment that she was encouraged to bring her daughter, who was wearing glasses for near-sightedness. The child was only ten years old, with a history of imperfect sight, which came on gradually and required strong glasses for its relief. With each eye separately or with both eyes, the vision was 10/200. I had her palm for about fifteen minutes. Immediately her vision improved to 10/10, or normal vision. Then I went out of the room and asked the mother to test the little girl's sight while I was gone. When I returned, the child's vision had relapsed to 10/200. I talked to the mother very strongly about the facts, and told her that near-sightedness was contagious. I impressed upon her mind as strongly as I knew how, that the child would recover by reading the Snellen test card, provided the mother was not in the same room. The child was not to wear her glasses again.

Some weeks later the mother reported that her daughter had obtained normal vision. She was tested daily by a relative with normal sight who did not wear glasses. One day the mother visited me at my office and was very much depressed. She said that her daughter had had a relapse. I asked her:

"Who tested her eyes?"

She answered, "I did."

I recommended her never to speak to her daughter about her eyes, and that all the testing should be done by somebody else. This happened five years ago, and I believe the child still has normal eyes and normal sight without glasses.

I have examined the eyes of a great many school children during the past thirty years. In all classes where the teachers had imperfect sight, or wore glasses, or suffered from eyestrain, a much larger percentage of near-sightedness was found than in those classes where the vision of the teachers was normal, or no eyestrain was present. This fact suggests that teachers should learn how to have normal sight without glasses.

Some of the teachers who were familiar with my methods of curing imperfect sight without glasses, taught the children how to **palm** and rest their eyes frequently during the day. The children were also taught how to **avoid the stare by swaying their bodies, their heads and eyes from side to side, alternately closing their eyes, remembering some letter perfectly, and then flashing the Snellen test card**. The teachers also taught the children the value of **blinking the eyes frequently**.

One teacher helped her pupils very much by having them write compositions on Palming, Swinging, and other methods for improving the sight. Many children were very much impressed by the value of relaxation, and encouraged other children, their parents, friends or neighbors to benefit their eyes in the same way.

Most teachers found that the treatment of imperfect sight improved not only the vision, but also increased the mental efficiency of their charges. It was very remarkable how the children's scholarship improved. Many of them with imperfect sight suffered from headaches and loss of memory. The relaxation exercises were of the greatest benefit in these cases. Some were found whose nerves were so sensitive that, although their scholarship was good, they failed to pass their examinations. In such cases a perfect memory or imagination of a letter or some other object was a complete relief, and their examinations became satisfactory. It was also interesting to learn that ill-behaved or mischievous pupils improved in their general conduct.

Many children suffer so much from headaches and other troubles when attending school, that they acquire a great dislike for their studies and prefer to leave school at an early age and go to work.

I have always had a great deal of sympathy for teachers. They certainly have a great deal to do. So many children are mischievous, and seem to take a cruel pride in making the work of their teachers more difficult. In this connection, I wish to call attention to the wonderful work of Ms. Hansen of Chicago, Ill., who has solved the problem, and has published an article in this number, telling how she did it.

This article was written for the purpose of encouraging teachers to practice relaxation methods, which always improve the vision and prevent children from acquiring imperfect sight. If the teachers should, in the presence of their pupils, practice reading the Snellen test card and other relaxation exercises, no doctor and no member of the Board of Education could object.

Palm and remember, imagine a letter clear and shift on it. Shift on any pleasant object in the mind and remember, imagine it clear.

Sway side to side in front of the eyechart, shift on a letter, remember it perfectly eyes open, then closed, still swaying.

Open the eyes again and flash the letter - shift on it for a fraction of a second, see it clear, then close the eyes. Repeat.

Swaying, flashing, shifting and closing the eyes prevents staring, strain, blur.

Natural Eyesight Improvement, clear eyesight improves the memory, imagination, relaxation, left and right brain hemisphere function, integration, all functions of the brain, personality. Children's school grades improve.

Sway

Move the body left and right and shift on a letter on the eyechart. Blink.

## STORIES FROM THE CLINIC

### No. 66: School children

By Emily C. Lierman

During the last year many school children have been benefited and cured of their imperfect sight at our clinic. Some had been wearing glasses, but a larger number had not worn them. The latter were cured quickly and in a few cases needed only one treatment. The records show that all those who were wearing glasses, obtained better vision without them. There were no exceptions. For the benefit of those who are interested in eye clinic work, I shall tell about a number of high school boys, all from the same school, who came for treatment.

A director of a Boys' Physical Training Department in one of our largest high schools in New York City heard of our clinic. About nine-tenths of the boys under his care were wearing glasses. Others struggled along without them, even though they had imperfect sight. The boys were between the ages of 13 and 17 years.

Late in the fall of 1924 one of them, by the name of Arthur, came with a note from the physical director. We accepted him gladly and he began treatment under the supervision of Miss Mildred Shepard, my assistant. His vision on the first day was 20/100 with each eye. It was noticed that his eyes were partly closed as he looked at the test card. When placed in a bright light, he had difficulty in keeping them open, and his forehead was a mass of wrinkles. Anyone observing him for the first time would have thought that Arthur never smiled. I thought so myself, as he appeared week after week, during the winter months and through the spring. Recently I treated him and helped him to read 10/10 on a strange card. I also received a shock. He smiled. By closing his eyes to rest them, and flashing each letter, he read 10/15 without a mistake. I wanted to stop his treatment then, because there were about twenty others waiting. Arthur begged, however, for one more chance. We gave him the sun treatment and then he returned to the test card and read 10/10. It was at that time I found that Arthur could really smile. **Palming, blinking and swinging, with sun treatment, cured him.**

The next case was William, whose vision was 10/200 with each eye. I do believe that William practiced faithfully at home and in other places, but he is just one of many cases of myopia who are slow in obtaining a cure. He is not discouraged, and knows that he will eventually have normal vision if he keeps on. His sight improved to 10/40, or one-fourth of the normal, in six months. The physical director wrote to me again, asking if he might send more of his boys who were anxious to get rid of their glasses. We have not the room nor the time to take care of even a small percentage of those who are crying out for help. I read the letter to Dr.

Bates. He did not answer right away, but just looked at me. Then he said: "Now, you know how much I love school children, and you also know how much I disapprove of glasses." I said: "All right, that settles it." My answer was: "Send them along. There's no limit to the number."

Twenty or more came in response to my letter, and all of them were nice boys. How glad I was that I wrote what I did. After they had received their first treatment, and I had spent more than three hours with them, Dr. Bates appeared at my room to ask if I were tired. His voice sounded most sympathetic. But I was perfectly relaxed, and not a bit tired. As I instructed the boys to palm and swing, I practiced with them. As their vision improved, so did my nerves become more relaxed. I was happy, but not tired. Treating the boys was not easy, but every one of them did as they were told, which made the task lighter.

Samuel had worn glasses about two years. He had a great deal of pain in his eyes and his sight was getting worse. The optician who had fitted him said he would have to wear them the rest of his life. His vision without glasses was 10/200 with his right eye and 10/100 with the left. **He stared continuously**, which, I believe, was the main cause of his pain. The first thing I did was to teach him how to **blink**. This relieved his pain. **Palming** and the **swing** improved his vision in both eyes to 10/50 on his first visit. Every time he was treated, his vision improved for the test card. At times he did not do so well, and he would apologize.

When I became better acquainted with Samuel he said: "You see. Mother is not forced to do it, but she peddles things, and helps my father to earn more money. In this way Mother will see that I can go to college." I told him that he should be very proud of such a wonderful mother. I look up to her with great respect and honor, because of her courage and sacrifice. Heaven bless such mothers! Samuel had to have four months' treatment before he could read with normal vision, but he was determined, and won out.

Abraham had symptoms of **St. Vitus' dance**, with a great amount of pain in both eyes. His vision was: right 10/15 and left 10/10. He had no organic disease of his eyes but the ophthalmoscope showed eyestrain. After three treatments the symptoms of St. Vitus' dance had entirely disappeared and he had no more pain. His vision also became normal, 10/10.

Morris hated glasses and wore them but a short time. He had normal vision in his right eye, but only perception of light in the left. I held the test card up close to his left eye, and told him to cover the right one. By **alternately blinking and flashing the white of the card**, he became able to see the letters as black spots. He was instructed to **practice with the test card every day, seeing the letters move opposite to the movement of his body**. While doing this he was to keep his right eye covered. After his third treatment he read the bottom line of the test card at three feet, or 3/10, with the left eye. He had been told by many doctors that nothing could be done for the left eye, because it was incurably blind. Dr. Bates examined him with the ophthalmoscope and said the trouble was called **amblyopia exanopsia, or blindness from effort**. Dr. Bates stated that such cases are usually pronounced incurable. Morris believes that with constant practice, there is no reason why he should not obtain normal vision in his left eye.

Benjamin had never worn glasses. For a long time the constant pain in his eyes made it difficult for him to study. The ophthalmoscope revealed only eyestrain. Right vision, 10/10; left vision, 10/20. After **palming** a short while and with the aid of the swing, the vision in his left eye improved to the normal 10/10. He had four treatments altogether. On his last visit I helped him to read 20/10 right eye and 20/20 left. He was instructed to practice with very fine print daily, and this, I believe, had most to do with relieving his pain permanently. He was more than grateful for the relief he obtained. He had a little brother, named Joseph, who was wearing glasses. Timidly he asked me would I help him, too. "Surely," I said. "Bring him along next time."

Joseph had been wearing glasses for three years, but his sight was not poor without them. Without glasses his vision was 10/15 with each eye. **Blinking while he was swaying improved his vision to the normal in five minutes' time**. He promised not to put his glasses on again, and came to me for four more treatments. These were really unnecessary because his sight stayed normal, 10/10. If our method had been in general use in the schools, this boy and others would not have been forced to wear glasses.

Hyman wore glasses four years for **progressive myopia**. His vision with his right eye was 10/100 and 10/70 with the left. After his first treatment he was able to read 10/50 with each eye. Constant daily practice, by **palming and improving his memory**, brought his vision to the normal, 10/10. This boy required only five treatments.

Charles wore glasses about four years, although he had no organic trouble, just eyestrain. His vision was 10/30 with each eye. He was told to close his eyes, and while **palming** to remember a small square printed on the test card. He was directed not to remember all parts at once, but to **remember or imagine one part best at a time**. His vision then improved to the normal, or 10/10. **Sun treatment** was also given him. Charles was cured in one visit.

Harry had worn glasses one year. His vision was 10/30 with the right eye and 10/70 with the left. Regular daily practice and the sun treatment improved his vision to 10/10 in three visits. Vows he will never wear glasses again.

Tobie was a fine, lovable chap a trifle younger than the rest. He was not so sure that he liked to see his name in print. I had mentioned the fact to all my wonderful boys, that I was going to write about their cases. He did not object very strongly when he realized that it would be a help to others. His vision was 10/50 with the right eye and 10/70 with the left. **Palming and sun treatment** improved his sight to normal, after three treatments. The rest of the boys were cured mostly with one treatment. It was only a matter of teaching them how to use their eyes right.

## MUSICAL APPRECIATION

By Elisabeth Hansen

Another year has passed, and Dr. Bates' system of relaxation for the eyes, mind and nerves has again been most successfully tried out. Every Monday morning the new Victrola record is used as a lesson for open discussion. The composer and artist is the very best, as we wish to instill in the children's minds an appreciation of the beauty, rhythm and style of the music. It is played all through the week, four times daily for five-minute periods.

Memory and Imagination Activity with Music

Before starting the record we devote two minutes to one of the various relaxation exercises, either the **long swing, swaying from side to side, the elliptical or variable swing**. Next comes the record, and the children, **while-palming, are to interpret it**. This is done sometimes by story, sometimes, as in an orchestral or string quartet number, they choose one instrument, and follow that through to the end. It is fine to ask them what feelings are aroused, such as gayety, calm, sorrow, noisy street scenes or

bravery. They love to do this. Then again the music is only an accompaniment for **imaginative stories**.

A conservatory in the park was visited by the whole room one day, and they **remembered** not only the gorgeous color displays, but the temperatures, and what grew best in those places. After their palming lesson, I asked them to write their **memory pictures**, and it made an excellent composition. What they wrote after palming, on how their pet dogs met them, and played with them made interesting stories.

Imagining the clouds as hills of snow, a sled, two boys or girls, usually in bright-colored sweaters and caps, made much fun. They enjoyed counting the little black "o" - remembering their favorite flower blossoms, but, best of all, to watch the fairies dance and play in the woods. (George Guild's Fairy Stories must be read to them every month. It would not do to miss that.)

What you have just read will give you an idea how we vary the palming period. When the music is finished, the children come back very happy, and once or twice a day they read silently the smallest letters of the **Snellen test card** seen from their seats, **both eyes and each eye separately**. The card serves two purposes: To keep them from becoming myopic, and also to teach them to print Roman type letters.

It is interesting to see how well and orderly they express themselves in their written composition work, their oral expression, and in the drawing lesson. It is pleasant to see them first look at the flower study or model, close their eyes, and paint as though it were the finest thing in the world to do.

From an educational standpoint, Dr. Bates' system is far-reaching, and can't be bettered in the training of memory and imagination. In silent reading, geography and history, where imagination plays such an important part, it works wonders.

### THE MAGIC FROG

By George M. Guild

Once upon a time, a long, long time ago, there lived a young frog who was very fond of travel and adventure. He became tired of sitting in one mud hole, where the only friends he had were other frogs. All the time he was on the move, trying to dodge the ducks and geese who were after him to serve as part of their dinner. He kept moving from one small pond to another, until he came to where there was no pond, where there was no mud, and no ducks or geese to dodge. The trees were high and grew closely together, so that the light of the sun was largely cut off. Much to his surprise, he found an open space all covered with nice, short, soft grass. When the sun went down, the place filled up with fairies. He was very grateful to them, because they did not try to steal his legs, for, as you know, some people are very fond of frogs' legs. When cooked in a hot pan with cracker dust and butter, they are delicious.

The fairies were surprised to see the frog and crowded around him to see him better. He was just as anxious to see them, and so he hopped on the top of the highest toad-stool he could find, and from this elevation he could see thousands and thousands of fairies, all dancing, laughing, and having a good time. The sight of so many fairies in all their bright colors dazzled him so that he was compelled to continually blink his eyes to avoid the glare.

The Fairy Queen was pleased with him, touched him with her magic wand, and transformed him into a Fairy Prince. He wore magnificent clothes, but looked queer with his long legs, short arms, and large, bulging black eyes. She gave him a magic white horse to ride. He soon mounted him with a high jump and gave a loud croak. The horse sprang forward and they were off. The fairies cheered and waved their hands. The Prince waved his hat, and they were soon out of sight of the fairies.

In a short time they came to a small house. The Prince got off his steed, tied him to a tree, walked up to the front door, and knocked. No answer. He knocked again and again, without success. Then he opened the door and walked in. Lying on a couch, fast asleep, was a young girl with her eyes covered with bandages. She was suffering great pain in her eyes. Much of the time she cried and screamed in her agony. The Prince was sorry for her and spoke to her kindly and gently. He told her that he was a Fairy Prince who had come to help her. This made her laugh and clap her hands for joy.

"Oh, I must see you," she said. "I have always wanted to see a Fairy Prince."

With her permission he removed the bandages with great care. He noted that the eyelids were enormously swollen, the eyeballs very red, and the pupils covered with thick white scars. She was quite blind. When she found that she could not see her Fairy Prince, she took his hand, pressed it against her sore, blind eyes, and began to weep softly.

She said, "You can cure me. Please do it." Then he lifted her in his arms, mounted his beautiful fleet, white horse, and galloped away from the dark woods out into the open fields where the sun shone at its brightest. She complained that the sun hurt her eyes, and pressed her face against his breast to protect her eyes from the glare of the sun. He advised her to hold her face up so that the strong light of the sun could shine on her closed eyelids. At first this was painful, but very soon the strong light felt more and more comfortable, and then the miracle happened. **The swollen lids became smaller, the redness of the eyeballs disappeared, and still more wonderful, the white cloud over her pupils melted away and she could see.** Her joy was unbounded.

"Oh, how handsome you are!" she said. "But why do you blink your eyes so much, just like a frog?"

"That may be," he answered. "I have been told that a long while ago one of my grandfathers was a frog."

"I don't care if you were a frog," she replied. "If you let me love you, when I grow up I will marry you."

They then rode on until they came to the woods where the fairies were. The Prince took the hand of the little girl and walked up to the Queen of the Fairies. He told her what he had done and that the little girl and he would like to get married after she had grown up.

Someone shouted: "The frog, he would a-wooing go." At once the Fairy Prince disappeared, and all that they could see of him was a frog, sitting on a toadstool, croaking as loud as he knew how.

The Fairy Queen was so indignant that I am quite sure the flames which started from her eyes would have burned up the speaker. She rushed over to the frog, touched him with her wand, and he again became a Fairy Prince. The Queen called out in a loud voice:

"You shall always be a Fairy Prince, and no one can ever change you back to a frog. When your little sweetheart has grown, be sure to bring her back to the fairies on your beautiful white horse."

The little girl ran to the Fairy Prince and threw her arms about his neck; she swayed from side to side, and when she swayed to the right the trees, the world, and all the fairies moved to the left. When she swayed to the left, everything moved to the right, but it made her eyes feel better, and she kept swaying from side to side for a long time.

The Prince and the little girl were very happy together, and in due time they were married and lived happily ever afterwards.

## SIX YEARS OF THE BATES METHOD

By M. F. Husted Supt. of Schools,

North Bergen, N. J.

It is very gratifying to learn that Mr. Husted obtained such wonderful results in the prevention of myopia in school children. He has been very enthusiastic about this method during the past six years, and has tested it with great care in a way that is eminently scientific. I believe the evidence he offers to be absolutely true. My experience during the last twenty years substantiates all that Mr. Husted has written - W.H.B.

Early in October, 1919, the North Bergen school nurse, Miss Marion McNamara, tested the sight of all our pupils. A new education was begun, a campaign for "Better Eyesight." In June 1920, a second test was made in order to measure the extent of progress and shows marvelous, practical, and successful results. This new effort in eye-mind education, to prevent and remove strain, adds to the already high educational efficiency of our schools by lessening retardation. *Not only does eye-mind education place no additional burden upon the teachers, but by improving the eyesight, health, disposition and mentality of their pupils, it surely lightens their labors and furnishes an additional means of preventing retardation.*

During the year 1923-24, every class in North Bergen schools, Grades II-VIII, became a conservation of vision class. Each classroom was visited by the Superintendent, and the values of good eyesight were dwelt upon. Pupils with normal sight volunteered to aid those with defective vision. They have engaged in this work with a helpful enthusiasm, and teachers have renewed interest. As this work is a physical training for the education of the eye-mind, teachers were instructed to use some time assigned to Physical Training or Hygiene to guide the below-normal vision pupils to sufficient proper eye practice for curative effects, and those with normal sight to sufficient practice for the prevention of eye defects.

Our records for 1924 show a startling condition of below normal vision among public school students. It also shows the miraculous results of eye-mind education in relieving strain. Of 128 pupils having glasses, 18 were found with normal vision and 111 had vision below 20/20. It is also shown that out of 4,026 pupils without glasses, 1,133 had below normal vision. The total below normal vision was 1,244 out of 4,155 Pupils.

The final results of our 1924 tests are remarkable for the improvement made, and show the wisdom of this special 1924 procedure and the great value of this wonderful discovery. Of 118 below normal pupils wearing glasses, 89 have improved, and out of 1,072 non-wearing glasses pupils with below normal vision, 693 have improved. Out of a total of 1,190 pupils with below 20/20 vision, 782 have improved. Of those that have improved, 342 have even attained normal vision.

Great care has been taken to make these reports accurate. The tests were all made by two nurses, assisted by the classroom teachers, and the reports were all made under nurse supervision.

Our 1925 records prove the wonderful effects of eye-mind education in relieving strain. Seventy percent of those wearing glasses improved; 87% of those not wearing glasses improved, and 56% of the entire number benefited attained normal vision.

## Conclusions

Because of the prevalence of pupils with defective vision, because of its great simplicity, and because retardation in schools furnished one of the teachers' greatest problems, eye-education is one of the great wonders of this age, and may become a boon of hope to the pupil, a boon of efficiency to the teacher, and a boon of mercy to humanity.

## BATES METHOD POPULAR WITH TEACHERS

Throughout the past year a group of teachers in one of the city high schools has been much interested in studying the Bates Method. One afternoon each week, from three to four, we have a "Bates class." The number attending has varied, sometimes being as many as fourteen. I feel that the total result has been eminently satisfactory. A great deal of enthusiasm has been aroused and many people helped.

Different individuals have, of course, presented different problems. One woman was beginning to feel that her near vision was blurring. She had never worn glasses. It seemed a very short time-perhaps not more than a month-before her eyes improved so that **she could read diamond type**. At present she is able to see the **microscopic print** in the little Bible.

A man who had worn glasses many years discarded them last December, and says now he has "forgotten how they feel."

Another teacher who took off her glasses two years ago, comes to the class once in a while for a little practice with us when her eyes feel tired.

A certain teacher with three diopters of hyperopia and presbyopia has made great strides. She has a vivid imagination and never-flagging enthusiasm. We both feel that her eyes will be normal some day in the near future.

The teachers who come to the class often look very weary. They always say they feel more rested at the end of the lesson.

Our procedure is the usual one of **palming, swinging, sunning** and working with the **Snellen test card** and **fine print**.

Some of the teachers who understand the method come to help teach the others. A student in the school whom I have trained always assists at the classes, and that makes the handling of the large group much easier.

I am intending to have a similar class next year, and I am sure we are going to accomplish even more.

### OPTIMISM

Optimism is a great help in obtaining a cure of imperfect sight. About ten years ago a patient was treated for **cataract**, complicated with **glaucoma**. After two weeks of daily treatment, the vision improved very much and the patient became able to travel about the streets without a companion to guide her. Her vision at this time had improved from perception of light to 10/200. After **palming**, **swinging**, and the **memory of perfect sight**, her vision was still further improved. She was very much encouraged and returned home full of enthusiasm to carry out the treatment to the very best of her ability.

Soon afterwards things did not go well at home. The patient became very much depressed and stopped her daily practice. Her daughter was very enthusiastic, and realized that her mother had been very materially improved and that further treatment would bring about a complete cure. She talked to her mother for half an hour or more and encouraged her to continue with her practice. The patient responded favorably, got busy, and was able to bring back much of the sight which had been lost. She made further improvement every day.

At times the mother was very pessimistic. She was continually complaining that she knew very well that she would never get her sight back. Then the daughter would start in with her optimism.

One bright, sunny morning the mother got up, took a card with diamond type printed on one side, and was greatly surprised to read it without any trouble. In three months her distant vision was normal.

### IRITIS

By W. H. Bates, M.D.

The colored part of the eye, which is visible by ordinary inspection, is called the iris. When the eyes are blue, the iris is the blue part of the eye. When this is inflamed it causes much suffering and, as a rule, the vision is lowered. Many general diseases cause iritis—rheumatism and syphilis are the most common. There are other causes, injuries and sympathetic ophthalmia.

When a foreign body becomes located inside of the eyeball of a healthy eye, more or less inflammation follows, with complete blindness in many cases. Unfortunately, the trouble does not always stop with the loss of vision in one eye. The irritation of the foreign body in one eye may have an effect upon the other. Iritis may then develop and lead to serious consequences. It is said to be sympathetic, meaning that the healthy eye sympathizes with the diseased or blind eye and also becomes diseased. Sympathetic iritis is very treacherous. Cases have been described which became blind from sympathetic ophthalmia within twenty-four hours. The only treatment that is at all efficacious is the removal of the eye containing the foreign body. Sometimes the operation is delayed too long, and after the healthy eye has become inflamed. In such cases removal of the eye with the foreign body may not be beneficial.

Some years ago a lady wrote to me in regard to her brother. She said that at the age of sixteen a bullet from an air gun had entered the inside of the left eye. He was taken at once to the hospital, where he received proper treatment. The surgeon in charge recommended that the eyeball be removed at once. The family refused to have this done so soon and put off the operation as long as they could. But things kept getting worse and worse, and the good eye became affected. The family at once consented to the removal of the eye, but it seemed to be too late. Although he was kept in the hospital a considerable time afterwards, receiving the best of treatment, the vision of the good eye declined more or less rapidly until there was very little left. At the age of thirty-two he visited me at my office. The vision of the right eye was the ability to count fingers at about three feet. He was unable to see any of the letters of the Snellen test card at any distance. With the ophthalmoscope the eyes showed evidence of previous inflammation, but the interior of the eye was so cloudy that I was unable to see the optic nerve with the retinoscope. I think most men who have seen these cases would agree with me, that things were not very promising. The man's sister told me, however, that they had not given up hope and visited every eye doctor who had been recommended. She said that no one was able to help him. The doctors very positively stated that it was impossible for the eye ever to get any better, and it would most likely become even worse.

As a matter of routine, I tried palming and swinging, but without the slightest benefit. When I asked the patient if he had a good imagination, he replied that he thought he had.

#### Memory and Imagination

With that I took the Snellen test card and held it at less than a foot from his eyes. I told him that at the top of the card was the letter "C" about three inches in diameter.

"Now," I said, "you don't see that letter 'C,' but if you have any kind of an imagination at all, you can imagine the 'C.' Can you not?"

"Oh, yes, Doctor," he replied, "I can imagine a sort of a big 'C,' but it is all blurred."

"Well," I said, "remember a letter 'C' that you have seen years ago, that was perfectly black, and had a white center which was perfectly white. You can remember having seen such a letter, can't you?"

"Oh, yes, I can," said the patient. "I not only can remember a perfect 'C,' but with my eyes closed I can imagine I see it."

"Well now, if you open your eyes, can you imagine you see it perfectly? If not, close your eyes and remember, or imagine it, as well as you can."

He practiced this imagination of a perfect "C" with his eyes closed and with his eyes open, alternately, for quite a while. After an hour had passed he said to me:

"Doctor, I don't see a perfect letter 'C' but I believe that now I can imagine I see it when I look at it with my eyes open."

When the "C" was placed more than a foot away, he became able to imagine it just as well as he had up close. With a little more practice he became able to imagine he saw a perfect "C" on a white card at ten feet. Then I asked him:

"Can you see any letters at all below the big 'C'?"

He said: "Yes, I see two smaller spots below it."

Then I told him that the first spot was a letter "R," and that I didn't believe he saw it.

He said: "No, Doctor, I don't see it, but I think I can imagine it."

"Can you imagine it perfectly?"

In a short time he answered, "Yes."

"What is the first letter that comes after the 'R'?"

"I don't see it," he answered, "but I imagine it is a letter 'B.'" This was quite correct. In a few days his vision improved to 15/10, or more than normal vision.

He demonstrated that when he imagined perfectly a letter that he knew, his sight was improved until he could see other letters that he did not know. I recalled the ophthalmoscopic examination I had made and that the **whole interior of the eye was filled with opacities which obscured the retina**, and which must have prevented him from having good sight.

The question came up in my mind: In what way did the imagination help his vision? With the ophthalmoscope I saw the **opacities in his eye become less when he imagined a letter perfectly; but, when he imagined a letter imperfectly the opacities reappeared.**

A second patient had **chronic iritis** for several years. At times the pain was so great that a number of operations had been performed, without benefit. The vision of the left eye was normal, while the vision of the right eye was only perception of light. He had **opacities on the front part of the eye, the cornea**, which lowered his vision. The pupil was filled with inflammatory material which obscured the interior of the eye. **On some occasions the eyeball of the right eye would be of stony hardness, while at other times the eyeball would be as soft as mush.** The eyeball was very hard when I first saw him. With the aid of palming, swinging and sun treatment the discomfort became less.

After the failure of the orthodox treatment for chronic iritis, it is of interest to report the great benefit which followed the "Imagination Cure." Like the other patient described above, the imagination of the known letters with his blind eye helped him to see letters that he did not know and the iritis was very much improved.

Look at the C on the eye chart. Remember, imagine and shift on the C in the mind with the eyes open, closed, open. Remember, imagine the C dark black, clear with a bright, perfect, pure white center. Open the eyes. The C on the eye chart will appear and be seen clear. Shift on the C. Then practice on smaller letters and at different distances.

## STORIES FROM THE CLINIC

### No. 67; Iritis

By Emily C. Lierman

Iritis is usually very painful, and causes a patient to feel much depressed. A matron of a Working Girls' Home telephoned me to ask if it were possible to treat a young girl under her care. This girl, Florence, was not the usual type one finds at the clinic. We made an exception in her case and admitted her, because she was an orphan. Both her eyes were bloodshot, and she continually tried to shield them from the light. Even ordinary light hurt her. The trouble began in her right eye, and shortly afterwards the left eye became inflamed. This was about a month before I saw her. She was treated by a number of competent eye doctors, who said she had iritis. They gave her drops to put into her eyes, but the pain still continued. Later, one of these doctors advised her to have her teeth and tonsils examined, but instead of doing this, she came to me.

Dr. Bates examined her eyes with the ophthalmoscope. Then he asked me to examine them also, and tell him what I saw. When I looked into the pupil of the right eye, I could see the whole area covered with small black spots. It looked very much like the top of a pepper box. Her left eye was also affected, but not so much as the right.

Her pain was so intense that I did not test her vision with the test card immediately. She was told to **palms and remember something pleasant. While palming, she described to me how her room was arranged. She remembered the figured pattern of the draperies on her windows, chairs and bed. She removed her hands and opened her eyes before I told her to, but the pain had disappeared**, and she wanted me to know it.

I placed her in the sun, being sure her eyes were closed. **The strong light was focused on her closed eyelids for a moment only.** She drew away from the light quickly, which is the usual thing for patients to do when they have never had the sun treatment before. I encouraged her to let me try again. She closed her eyes as she was told and I led her into the sunlight once more. She liked it.

Florence was advised to blink often and to palm her eyes early every morning, and during the day when possible. Six days later I

saw her again. The ophthalmoscope showed a decided improvement in the pupil of her right eye. There were only a few small spots on one side of it. The left pupil was entirely clear. Florence said she had been working unusually hard, and also late at night, feared that the vision of her right eye would not be so good. She read 10/15 with the right eye on a strange card, but the letters were not clear. After she had rested her eyes by **palming** and practicing the **sway**, the letters cleared up, and she read 10/10. Her left eye had normal vision. Then I gave her the sun treatment again.

The third time I saw her, which was also her last visit, both eyes had normal sight, and her pain had disappeared entirely.

Later we had another case of iritis, a woman much older than Florence. She was almost insane with pain in both her eyes. I could not do anything with her for an hour or more because of her extreme nervousness. I placed the palm of my right hand over her closed eyes, as she leaned her head against me. Fortunately, she had her little girl, Betty, with her. While I palmed the poor mother's eyes, I held a conversation with Betty, solely for the benefit of her mother.

Betty was telling me how her mother suffered all day long, and at night she had walked the floor because she could not sleep with the pain. Mother love is one of the greatest things in the world. I could feel the mother relax as I held her close. Then she began to talk of Betty's good qualities, and what a help she was. I placed the mother in the sun, still keeping her eyes covered with the palm of my hand. Then I held my sun-glass in position, so that the strong light of the sun would focus directly on her closed eyelids when I removed my hand. Knowing that the strong sunlight had been painful to her during her illness, I did not tell her what I was about to do. I planned to use the sun-glass very quickly, and not give her a chance to strain. I did it successfully, although I feared I would not. Some patients strain so in their agony that it is difficult to use the sun-glass the first time. After the first treatment this patient enjoyed it.

The vision in both eyes was 10/40, but none of the letters were clear. After the use of the sun-glass I encouraged her to palm, while Betty and I started another conversation. The subject was all about her baby brother. Betty would exaggerate once in a while about some of the things brother did. Her mother would correct her, and explain things differently. This was just what I wanted. Anything but the memory of her discomfort would be a help. She was temporarily relieved of her pain when she left the clinic.

Betty was invited to come with her mother at her next treatment. An eye specialist was visiting us at this time, and, after his examination with the ophthalmoscope, he pronounced it a bad case of iritis. He was quite positive that she could not be cured in less than six weeks. My patient came every day for one week, and at the end of the second week she was entirely well. During the time that her pain was being relieved her vision also improved. **The only methods I used were sun treatment, palming, and perfect memory.**

I did not realize how great a help Betty was during her mother's treatment, but after her mother was cured I found out. When patients suffer intensely I seem to feel it. I unconsciously lower my voice, and speak as softly as I can. I believe that we all respond to kindness, and this we need most of all when we are ill. Betty repeated to her mother at home a great deal of what she had heard me say at the clinic. She tried to use the same tone of voice, and smoothed her mother's throbbing forehead. She even did this during the long nights when sleep was an impossibility. Truly, Betty was my assistant in the cure of her mother's eyes.

## THE CONGO TREE

By George M. Guild

[“The Congo Tree” was written for the benefit of the children. It will help them to obtain relaxation when someone with perfect sight reads it aloud slowly, while the children listen with their eyes closed or when palming. The tree receives its name from a river in Africa, which is a very important river, indeed. It is a magic tree very much appreciated by fairies. The flowers that grow on it are very beautiful and their fragrance is so sweet and delicate that not only do the fairies enjoy it, but also everybody else. Children with imperfect sight and sore eyes, and those who suffer from headaches, are cured at once of all their troubles when they carry away some of the flowers from the Congo tree. The leaves are of great value, too. If a child holds one of these leaves to his ear, the leaf will talk to him in a language that he can understand. It will tell the child how to be happy and enjoy perfect sight without glasses.]

And now the merry jingle  
Of fairies dancing single;  
Watch them come and watch them go,  
Bowing high and bowing low,  
Always smiling, singing, glad,  
With their laughing, never sad.  
Happy, happy, they will be  
When they see the Congo tree.  
They will climb up to the top,  
Swinging, swaying, never stop,  
As they move, the earth goes round  
With the sky, and with the ground.  
Ev'ry leaf upon this tree  
Knows a lot of how to see.  
This Wonder Tree has a heart  
Full of love in ev'ry part.  
A tall, heavy tree, all right,  
Its top seems out of sight.  
The Congo tree is hailing,  
To all whose sight is failing,  
“Let me help you to a cure,  
Come quickly, while it is sure.”  
Georgie Fairbanks came to see  
All about the Congo tree;

It might cure his eyes so sore  
 Of their pain forevermore.  
 Without glasses he might play  
 Ev'ry night as well as day.  
 The fairies can, they so kind,  
 Cure his eyes, a long time blind.  
 The fairies came, took his hand,  
 Led him forth, a smiling band.

The Congo tree was weeping,  
 Awake, and yet 'twas sleeping  
 While Georgie had a queer dream,  
 Things were not as they might seem.  
 Blind he was, and yet could see.  
 Strange, how could that wonder be?  
 When his eyes were closed tight  
 All things were as black as night.  
 He could count up to seven,  
 Add four, which makes eleven.  
 The Congo tree sways much more,  
 A hundred thousand, add four.  
 The tears it shed made it dry-  
 Many quarts from each eye.  
 Wake up, Georgie, do your best,  
 Shift and swing after your rest.  
 No more glasses, no more pain,  
 The Congo tree once again  
 Is ready to help your eyes.  
 Hurry, for fast the time flies.  
 Now it did not shed a tear,  
 Neither did it have a fear.  
 Ev'ry leaf and branch could see  
 All the fairies in their glee.  
 The Congo tree was talking,  
 Each special branch knew something,  
 Its roots on truth were founded,  
 And they were deeply grounded.  
 Georgie woke from his dream  
 And saw things as they might seem.  
 The fairies told him to read  
 Fast or slow with some speed;  
 Also he should often blink,  
 And as fast as he could think.  
 Remember what he saw best,  
 Always taking a good rest.  
 The fairies came and sat down  
 Cross-legged on the warm ground,  
 And then they began to sing  
 "we have a Queen, but no king."  
 The only man who was there  
 Was a youth with curly hair.  
 While his eyes were on the Queen  
 A fairy crept close unseen,  
 Cut away one of his curls,  
 Decked it with some fine pearls,  
 Then threw it all in the air,  
 "A trophy to the most fair."  
 What a scramble, what a fight  
 Before 'twas won and held tight!  
 By a fairy, meek and mild,  
 But full of fun as a child.  
 She looked round for her knight,  
 But he had gone from their sight.  
 Only Georgie saw him go  
 With the Queen, and not so slow.  
 He saw him with the Queen fly  
 Very fast, toward the sky.  
 Georgie's eyes were now all right,  
 Seeing fine by day or night.

### A HANDY POCKET-SIZE TEST CARD

This small test card measures 3 ½ by 6 ¼ inches. It is a combination of helpful instructions, fine print, and test card. On one side is printed the Snellen Test Card reduced in size. The other is devoted to the fundamentals of treatment, printed in graduated type.

The important, helpful feature of this card is that it can be conveniently carried in a purse or coat pocket. One side of the card improves the near or reading vision, while the other improves the vision for the distance.

Price 10c.

### THE EFFECTIVENESS OF RELAXATION

By May Secor

Special Teacher of Speech Improvement, New York City Public Schools

**STAMMERING**, stuttering, lisping, and other speech defects may be considered erroneous speech habits which may be corrected by inculcating new, correct habits of speech. This presents a psychological problem. There is, however, another aspect to the work of speech correction - a physiological aspect. Many cases of speech defect are difficult to correct, because of the physical condition of the pupils. It is considered an important duty of the speech improvement teacher, therefore, to check up physical conditions and to advise parents to have corrected such defects as eyestrain, unhygienic dental conditions, malnutrition, and excessive fatigue.\*

(I believe, however, that it is not the province of any teacher, principal, or nurse to advise, urge, or insist upon parents having children operated. Those in charge of children may, with propriety, advise parents to consult physicians regarding their children. In many cases, however, physicians differ among themselves as to the advisability of operating. I believe that the decision should be made by the physicians and parents.)

Many stammerers suffer from eye-strain. For years I urged the patients of such children to consult oculists - any oculists of good standing. They did so, and many cases returned with glasses; however, many of these children who used glasses continued to suffer from eyestrain. Upon returning to the oculist they were usually instructed to continue wearing their glasses until they "became accustomed to them." In many cases eyestrain continued, and the correction of stammering was still impeded. I was deeply concerned about the apparent impossibility of eliminating eye-strain.

Finally a friend placed in my hand Dr. Bates' book entitled "Perfect Sight Without Glasses." At that time I was wearing bi-focals, and had used artificial lenses for many years.

I read Dr. Bates' book and decided to apply the method to the correction of my own visual defects.

On March 15, 1923, I removed my bifocals. I followed the Bates Method carefully, hopefully, and persistently and have never used glasses since. My near vision and distant vision are excellent and I enjoy great "eye comfort." I have come into contact with many other men and women who have attained normal vision without glasses by means of the Bates method, after having suffered along with eye-glasses and eyestrain for years.

Convinced of the efficacy of the Bates Method, I became a pupil of Dr. Bates and learned the **secret of relaxation**. I learned how to **relax more completely**, and how to help others relax. I began to realize the value of relaxation in education. I made relaxation the keynote of my work in speech correction, and there resulted a harmony that was most helpful to my pupils. It created a pleasant, healthful atmosphere, which enabled pupils to acquire more readily the desired, correct habits of speech.

**To the stammerer, especially, palming, swaying, swinging, sun-treatment, and reading the Snellen card** are Godsend.

In April 1925, I began work with the speech defect cases in two new schools. Among these cases were a number who wore glasses, and several of these children were **cross-eyed**. (The term "squint" is frequently misinterpreted.) To induce relaxation and thereby facilitate the formation of new, correct habits of speech I included in my program **palming, swaying with music, swinging, the use of memory and imagination, and sun treatment**. Early in June 1925, it became apparent that several pupils, who formerly were very noticeably cross-eyed, showed either no defect or a decidedly less acute condition. To verify my observations I photographed these children. I also requested several teachers, and a physician to observe them; they did so, and their findings coincided with mine. The following children were among those who entered my speech improvement groups early in April 1925:

+Case A - Boy, age 14; myopia and strabismus (crossed-eye, called also "squint"); used glasses several years; speech defects, stammering and lisping; known in school as a discipline case. June, 1925 - marked improvement in speech and strabismus entirely corrected.

+Case B - Boy, age 11; myopia and strabismus; used glasses two years; speech defects, stammering, defective phonation, and aphonia. June, 1925 - marked improvement in speech; strabismus much less acute, and entirely relieved at times, when glasses are not used.

+Case C - Boy, age 7; myopia and strabismus; never used glasses; speech defect, lisping. June, 1925 - speech improved; strabismus relieved - occasional relapse when under strain.

+Case D - Girl, age 8; strabismus (but normal vision); wears glasses, constant use; speech defect, lisping. June, 1925 - lisping corrected; when glasses are removed, strabismus is very evident and child sees "two ladies instead of one;" after removing glasses and relaxing a few minutes, strabismus and double vision disappear; subsequent use of glasses causes return of these two defects, which again disappear after the child removes the glasses and relaxes.

In these cases the relief of visual defects was merely a by-product of educational work, conducted on a basis of relaxation. Would it not be well for us to conduct all educational work in this way, and thus help to relieve eyestrain throughout our schools?

Let us consider the problem of the child having visual defects. What method has been used to help him? He has been urged to wear glasses, and if his eye distress or headaches persisted, he has been urged to continue wearing the glasses until he "becomes accustomed to them." Has this method been successful? Reports of the various sight conservation associations indicate that it has not been successful. What new method may we use to eliminate visual defects among school children? I suggest the Bates Method for Relaxation. Let teachers remove their glasses, and palm, sway, and swing. Let physicians and principals urge pupils to remove their glasses and practice these helpful exercises. Let us, as educators, be broad-minded and alert. When one method fails let us try another.

Relaxation occurs in many forms. See: Dynamic Relaxation - Book; The Art of Seeing by Aldous Huxley. Perfect relaxation can be deep as in the alpha, theta and delta brain wave states, hypnosis, meditation or dynamic: the mind, body, eyes can still be relaxed

while more active, energetic. Example: when running a race; the runner is in a perfect state of relaxation, coordination. Mind, body positive, energetic, active but relaxed - no tension, strain. Walking in a relaxed strolling manner. (See Al Pacino walking in the park with his girlfriend in 'The Godfather' movie. Notice how his feet move outward, relaxed, strolling, perfect balance, coordination, character in his walk.)

Working on a science project, mind moving from thought to thought, no tension is dynamic relaxation. See Better Eyesight Magazine April 1925 - Concentration and Relaxation.

## THE STORY OF JOHN

By Mary M. Campbell

Most of the books written by eye-doctors state that holding the book close is very bad for the eyes. It is also advised that children should read in a good light without leaning over. It has been a very strong belief that when the child leans over to read, the blood gravitates to the eyes and produces imperfect sight. Bending the head/neck down for a long time causes stiff neck muscles which place tension on the nerves, blood vessels in the neck, lowering circulation of blood, oxygen, and nerve signals through the neck to the head, brain, ears, eyes. Dizziness, lowered vision can occur.

When my son, John, was less than four years of age we believed that his vision was poor and took him to an oculist for treatment. He at once prescribed very strong glasses, and told us that unless we compelled the child to wear them constantly he would most certainly become blind. With this calamity hanging over us all the time, we went to a great deal of trouble to carry out the doctor's orders.

When John was six years old we placed him in the kindergarten. He was quite contented there and enjoyed all the different exercises. The teacher had a long talk with us about his eyes, and told us that she thought that he had perfect eyes and did not need glasses. We consulted another oculist, who found that his vision for distance was unusually good and that all of the glasses tried made his sight worse. We asked him if there was any danger of the boy going blind if he did not wear glasses. The Doctor smiled and said: "There is nothing the matter with the boy's eyes; he doesn't need glasses."

Then the Doctor tested his ability to read fine print - diamond type. He read it at about three or four inches from his eyes without any trouble. Then he was asked how far off he could read it, and to our surprise he read the fine print almost as well at arm's length as he could up close. The Doctor said that it was very evident that he did not need any glasses for reading. We said, "But, when John reads a storybook, he always holds it very close to his eyes, and many people have told us that he did it because he was inclined to be near-sighted, and if we permitted him to do this, he would most certainly lose his ability to see at the distance and would have to wear glasses the rest of his life. When he becomes interested in a storybook he keeps on reading after the light fails. We have seen him reading after dark, just by the light of the moon."

The Doctor told us that it was all right for him to read by moonlight as long as he enjoyed it. He said it could not do John any harm. Since reading Dr. Bates' book I have found that he recommends that young children be encouraged to hold the book as close to their eyes as they desire and to read as much as possible for as long as the child is interested. Near use of the eyes, even when under a strain, always lessens near-sightedness and never causes it. As long as the child can read without discomfort at the near point, that child should be encouraged to continue reading in this way.

Read without strain at all distances for clear vision at all distances.

One day John came home from school and complained that he had a headache. At once all our old fears returned and we made an appointment with the eye-doctor to see him the next day. The next morning John's headache disappeared, but we took him to the doctor just the same.

The Doctor asked him: "Did you have the headache in school?"

John answered: "No sir."

"When did you get the headache?"

"About an hour after I left school," he answered.

"What were you doing at that time?"

John replied: "I wasn't doing anything."

Then his sister, who was present, spoke up: "I saw you with a lot of other boys eating green apples."

John blushed and admitted the facts. The Doctor told us that what we should do was to consult our family physician if anything went wrong with John before taking him to an eye-specialist. It seemed a queer thing for an eye-specialist to say, but we followed his advice, and whenever anything went wrong with John the old family physician relieved him without glasses.

Boy reading Comic Books by moonlight. Children have improved their vision by reading comic books. Comics are fun, interesting, entertaining, relaxing, improves the memory, imagination of clear mental pictures, gets the eyes moving, shifting.

## QUESTIONS AND ANSWERS

Q - a - Does the improvement of the sight by the Bates Method increase the rapidity of reading?  
b - Is slow reading conducive to strain?

A - a - The better the letters are seen, the more rapidly they can be read.  
b - Yes.

Q - Do weather conditions affect the sight?  
A - They often do. When the eyes are normal the weather does not disturb the sight as much as when the sight is defective.

Q - Is cataract curable after an operation?  
A - After a cataract operation, the crystalline lens of the eye is removed. A large amount of hypermetropia is manifest. Strong

glasses are usually required to improve the vision. These cases have obtained normal sight for distance and for reading by my method without glasses.

Q - How long is it necessary to follow your method before a cure is effected in a case of astigmatism?

A - These cases require a variable length of time. Some are cured in a few weeks, while others may require many months.

Q - My sight is good, but my vision blurs and the eyes pain. Will glasses relieve this condition?

A - I would not expect glasses to give you any relief.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

OCTOBER, 1925

### READ FINE PRINT

Many nearsighted patients can read fine print or diamond type at less than ten inches from their eyes easily, perfectly and quickly, by alternately regarding the Snellen test card at different distances, from three feet up to fifteen feet or further. The vision may be improved, at first temporarily, and later, by repetition, a permanent gain usually follows.

It is a valuable fact to know, that when fine print is read perfectly, the near-sightedness or myopia disappears during this period. It can only be maintained at first for a fraction of a second, and later more continuously.

Nearsighted patients and others, with the help of the fine print can usually demonstrate that staring at a small letter always lowers the vision, and that the same fact is true when regarding distant letters or objects.

With the help of the fine print, the nearsighted patient can also demonstrate that one can remember perfectly only what has been seen perfectly; that one imagines perfectly only what is remembered perfectly, and that perfect sight is only a perfect imagination.

A great many people are very suspicious of the imagination, and feel or believe that things imagined are never true. The more ignorant the patient, the less respect do they have for their imagination, or the imagination of other people. It comes to them as a great shock, with a feeling of discomfort, to discover that the **perfect imagination of a known letter improves the sight for unknown letters of the Snellen test card, and for other objects.**

It is a fact, that one can read fine print perfectly, with perfect relaxation, with great relief to eyestrain, pain, fatigue and discomfort, not only of the eyes, but of all other nerves of the body.

### SOME TRUTHS

By W. H. Bates, M.D.

*Normal sight can always be demonstrated in the normal eye but only under favorable conditions.*

It has been generally believed that the normal eye has normal sight continuously. This is an error. The normal eye does not have normal sight all the time. It has always been demonstrated that distance, illumination, size or form of the letters or other objects, and other conditions, affect the vision of the normal eye, or that conditions favorable to some normal eyes are not favorable to all. It is normal for the clarity of vision to fluctuate: Clear, less clear, back to clear. Avoid eyeglasses and the vision will always return to 20/20 and clearer.

### DISTANCE

Most normal eyes have normal sight when reading the twenty foot line of a test card at twenty feet. Of these, a smaller number do not have normal sight at thirty feet or further. Some others do not see so well at a nearer distance, fifteen, ten, or five feet. Still others may have normal vision when tested at different distances from twenty feet to five feet, and have imperfect sight at more than twenty feet or nearer than five feet. One patient at times could see the moons of the planet Jupiter with normal sight when the eyes were normal; but at twenty feet the vision was imperfect, and remained imperfect for nearer points, until tested at six inches, when the vision and the eyes were again normal. Vision can be clear, unclear at a variety of different distances.

It is a truth that the distance of the test card when read with normal vision, varied daily, and in some cases within wide limits. These facts suggest that eyes with imperfect sight are improved more satisfactorily when treatment is employed with the test card placed at a distance where the results are best. In myopia, or nearsightedness, with the vision normal at one foot or nearer, improvement in the vision at a greater distance occurs by alternately reading the card at a near point, and a few inches further off.

It is a truth that when the eye is normal when regarding a letter or some other object at two feet or further, it may remain or continue normal for part of a minute, and when regarding a letter or other object at a greater distance, it may remain normal for a fraction of a second. By repetition the flashes of improved vision occur more frequently and last longer.

### ILLUMINATION

The illumination is important. As a general rule, vision is normal in the normal eye when the light is good. This rule has many exceptions. It is a truth that some normal eyes may have normal sight only in a dim light. One patient suffered from the annoyance of ordinary daylight to an extreme degree. At twenty feet only some of the larger letters were read without glasses. After the light was lessened by screens, the vision improved to the normal. After sun treatment the patient obtained normal vision in a strong light, as well as in dim light.

$\frac{20}{20}$  Distance - 20 Ft.  
Size of letter,  
line looking at.

## ENVIRONMENT

The environment may be favorable or unfavorable. Teachers in the public schools with normal eyes, normal sight without glasses, had more pupils with normal eyes than those teachers with imperfect sight, or who were wearing glasses. Teachers have cured their pupils by treatment without glasses while curing their own eyes at the same time. Many people are great imitators. In schools where the pupils are ambitious to obtain normal sight without glasses, those with imperfect sight are influenced to do likewise: read the **Snellen test card**, practice the **swing and rest their eyes frequently by closing them or by palming**.

School children with imperfect sight have been treated and cured. **The cured children often helped or cured the imperfect sight of other members of their family, their neighbors, and their friends.** The facts have been published from time to time in this magazine and elsewhere.

A child aged five had a well marked turning of one eye inward toward the nose. The condition was noticed soon after birth. The mother said that the child was very nervous, and when playing with other children who were also nervous, her eyes were worse; but, when she enjoyed the play, she was not nervous and her eyes were straight. The mother, the child and I played "Puss in the Corner" and made it a very noisy affair. The child screamed with laughter and even the mother smiled. The eyes became straight and remained straight as long as the patient was comfortable. But when the environment of this patient became annoying in any way, the eyes turned. The mother was advised to teach the patient many games which amused or interested her. The object of the treatment was to encourage relaxation.

The cause of death among many **aviators** has been believed to be due to attacks of blindness from eyestrain. Flying through dark clouds, in storms of wind, rain or snow, the environment may quite readily cause imperfect sight from eyestrain. But even with the weather conditions favorable, aviators have testified that attacks of blindness may occur without the victim knowing the cause.

This subject has been more fully discussed in the **N. Y. Medical Journal of September 8, 1917.**

From Better Eyesight Magazine - June, 1925:

If you learn the fundamental principles of perfect sight and will consciously keep them in mind your defective vision will disappear. The following discoveries were made by Dr. Bates and his method is based on them. With it he has cured so-called incurable cases;

- 1-Many blind people are curable.**
- 2-All errors of refraction are functional, therefore curable.**
- 3-All defective vision is due to strain in some form.**
- 4-Strain is relieved by relaxation.**

You can demonstrate to your own satisfaction that strain lowers the vision.

When you stare, you strain. Look fixedly at one object for five seconds or longer. What happens? The object blurs and finally disappears. Also, your eyes are made uncomfortable by this experiment. When you rest your eyes for a few moments the vision is improved and the discomfort relieved.

Have someone with perfect sight demonstrate the fundamental principles contained in Dr. Bates' book, "Perfect Sight Without Glasses." (Original book is; *The Cure Of Imperfect Sight By Treatment Without Glasses*) If the suggestions and instructions are carried out, and glasses discarded, it is possible to improve the vision without personally consulting a physician.

"Perfect Sight Without Glasses" will be sent C.O.D. on five days' approval. \$Price, \$5.00.

### THE IMPERFECT SIGHT OF THE NORMAL EYE

**New York Medical Journal,  
Sept. 8, 1917, Page 440-442**

**By WILLIAM H. BATES, M.D.**

It is generally believed that the normal eye has perfect sight all the time. It has been compared to a perfect machine which is always in good working order. We have been taught that the normal eye is always normal and that the sight is always perfect, no matter what the object regarded may be, whether new, strange, or familiar, whether the light is good or imperfect, or whether the surroundings are pleasant or disagreeable. Even under conditions of nerve strain and bodily disease, the normal eye is expected to have perfect sight always.

A scientific study of the facts has convinced me that this impression so generally believed and taken for granted is far from the truth. After thirty years special study of the refraction of the eye under different conditions I am convinced that the normal eye has imperfect sight most of the time. It is unusual to find persons who can maintain perfect sight continuously longer than a few minutes under the most favorable conditions. Of 20,000 school children studied by me, more than one half had normal eyes with perfect sight. Not one of them had perfect sight in each eye every day. The sight of many of them might be good in the morning and imperfect in the afternoon, while many with imperfect sight in the morning would have frequently perfect sight in the afternoon. Many children with normal eyes would read one Snellen test card with perfect sight, a second and different one with imperfect sight. Many children could read some letters of the alphabet with perfect sight but were unable to distinguish other letters of the same size under similar conditions. The amount or the degree of the imperfect sight varied within wide limits from one third of the normal to one tenth or less. The duration of the imperfect sight of the normal eye was also variable. Under some conditions in the classroom the imperfect sight might continue for only a few minutes or less. Under other conditions, however, a small number of pupils, sometimes all the pupils with normal eyes would have sufficient loss of sight to prevent them from seeing writing on the blackboard for days, weeks, or longer.

Adults with normal eyes do not have perfect sight all the time and what has been said of the normal eyes of school children is also true of them. Age is no exception. Persons over seventy years of age with normal eyes have had attacks of loss of sight variable in degree and duration. The retinoscope always indicated an error of refraction when the sight of the normal eye was imperfect. A man eighty years old with normal eyes and perfect sight had periods of imperfect sight which would last from a few minutes to several hours or longer. Retinoscopy always indicated myopia, sometimes 4D or more. Many adults with normal eyes, as well as children have attacks of color blindness. One patient with normal eyes with perfect sight and perfect color perception in the daytime has always been color blind at night. He had no perception of colors after sunset. It is true that all persons with normal eyes are always less able to distinguish colors correctly during the time that their sight was imperfect. Accidents on railroads, collisions, and other accidents at sea, trolley car accidents, automobiles with their high daily death list, occur usually because the normal eyes of the responsible persons for a time had imperfect sight. Accidents occur when nervous children or adults cross the street. They become confused, blinded, and are struck by automobiles, trolley cars, are injured because, although they had normal eyes, their sight was lost.

### CAUSE

There is but one cause of functional imperfect sight, a strain or effort to see. The normal eye with good sight is at rest, but, with imperfect sight, the retinoscope always indicates an error of refraction sufficient to account for the defect in the vision. The strain may be an unconscious strain or it may produce results on the eyes, pain, discomfort, fatigue, of which the individual may be conscious. Quite often the strain may be a conscious effort without the production of discomfort. In all cases of strain it can be demonstrated that the eyes do not see best the point fixed but some other point to one side—the eyes do not see best where they are looking. If one letter or one word of a line is regarded, other letters or words on the same or other lines will be seen as well or better when the eyes are straining or making an effort to see.

The normal eye can be made to strain consciously by making an effort to see a letter or word better than the one regarded. The vision is always lowered for the letter or word regarded and an error of refraction is always produced. Unfamiliar objects cause eye strain and are never seen perfectly. School children with normal eyes who can read with normal sight small letters one quarter of an inch high at ten feet always have trouble in reading strange writing on the blackboard although the letters may be two inches high. Myopia, temporary or permanent, is always produced. Strange maps always produce imperfect sight in the normal eye because they cause a strain or effort to see.

When the eyes are used for near work the normal eye is seldom properly focused. The retinoscope has always demonstrated that when an effort or strain is made to see more clearly at twelve inches, twenty inches, or less than twelve inches, the eyes are always focused at a greater distance with the production of astigmatism, usually temporary, but which has been observed to become permanent. Of course with the eyes not properly focused the vision is defective. School children and adults learning to read, write, draw, sew, or to do mechanical work suffer from defective vision although they have normal eyes. This matter is of such practical importance that the attention of teachers should be called to the facts. Many children lose interest in their school work, become truants, incorrigibles, and chronic sufferers from headaches and other neuroses who might have been relieved by proper treatment. I have described the relief obtained by school children when the teachers understood the problem (1)

Light has a very important effect on the vision of the normal eye. An unexpected strong light always produced defective vision. The vision of all persons is imperfect when the eyes are first exposed to the strong light of the sun or to strong artificial light. Rapid or sudden changes in the intensity of the light always produce defective vision, not always sufficiently great to be manifest to the individual but which can always be demonstrated by careful tests of the vision and by use of the retinoscope. The defective vision produced by strong light may be temporary but it has been observed to continue in many cases for a number of weeks or months. It is never a permanent disability. Persistence in regarding a strong light after a time becomes a benefit. Some persons have become able to look directly at the strong light of the sun without any loss of vision whatever. When the light is dim or at night, the vision of the normal eye is usually good; but, when an effort is made to see, the vision becomes imperfect and the retinoscope indicates always an error of refraction.

Noise is a frequent cause of defective vision of the normal eye. All persons see imperfectly when they hear an unexpected loud sound. Familiar noises do not lower the vision usually, but unfamiliar, new, or strange noises always do with the production of a temporary error of refraction. Country children from quiet schools, after moving to a noisy city, may suffer from the effects of defective vision for long periods of time, weeks, months. In the classroom they do not do well in their work because their sight is impaired. It is a gross injustice for teachers and others to criticize, scold, punish, or humiliate them.

Moving pictures usually produce defective vision which is always temporary. Some of my patients have complained that they always suffered with pain and had poor sight whenever they regarded the screen with its flickering light. I believe that some years ago when photography was less perfect than it is now the pictures produced a great deal of eye strain, much greater than that at the present time. I always advised my patients under treatment for the cure of defective vision without glasses, to go to the movies frequently, practice central fixation (2), and become accustomed to the flickering light. They soon became able to stand the strain without loss or impairment of their vision. Other lights and reflections from smooth surfaces became less annoying and it seemed true that after the movies were unable to produce a relapse other lights were unable to lower the vision after they were relieved of errors of refraction, myopia, hypermetropia, and astigmatism by treatment.

### TREATMENT

Eye training with the aid of a Snellen test card at ten feet or farther is very successful in correcting and in preventing the imperfect sight of the normal eye. One may use a distant calendar, a sign with small letters, or one small letter for daily practice. The normal eye is readily trained to read the Snellen test card with normal vision or to see other letters or figures or one known small letter at a distance of ten feet or farther. The vision always improves and becomes better than that of the average normal eye. The practice of reading known or familiar letters once daily or more frequently with normal sight by the normal eye is a decided benefit and lessens the tendency to strain when regarding unfamiliar letters or objects.

## RESULTS

On my recommendation more than 20,000 school children have practiced eye training daily with the aid of the Snellen test card. The results were of great practical importance. The vision of the normal eye was always improved when the teachers used the method properly. Because the sight was always improved, myopia was always prevented. This is the first published method for the prevention of myopia which was successful. Many children wearing glasses to benefit imperfect sight, pain, and fatigue of the eyes, and headaches were relieved so completely that they became able to discard their glasses and obtained more perfect sight and a greater relief to their eye pain and headaches. The eye training demonstrated by the good results obtained that many thousands of children in the schools are wearing glasses that they do not need because their eyes are normal.

Artists, bookkeepers, lawyers, physicians, writers, mechanics, and others found their efficiency increased many times with the aid of eye training. Many recruits for the army and navy were found to have imperfect sight and were rejected, although their eyes were normal. Eye training improved their sight. Later they read the Snellen card with perfect sight and were accepted.

## CONCLUSIONS

1. All persons with normal eyes and perfect sight do not have normal eyes and perfect sight continuously.
2. The cause is always an effort or strain to see.
3. Treatment by eye training is successful when distant, small, familiar letters, are read a few moments at least every day.
4. The good results obtained justify the use of the method in all schools, the army, the navy, the merchant marine, on all railroads, in short by everybody who desires or needs continuous perfect sight.

## STRAIN DURING SLEEP

It is a natural question to ask: "Does sleep secure relaxation of the eyes? How many hours should one sleep to prevent imperfect sight in normal eyes?"

It was a great shock to me to find that patients with normal eyes were under a much greater strain when asleep than when they were awake. I do not know why. It is a truth that when the eyes are normal, there is no strain and they are at rest. Anything that is *done* is always wrong, and lowers the vision, because normal eyes only remain normal when the vision is normal. During sleep one is not conscious of the strain of imperfect sight. But the first thing in the morning the symptoms of eyestrain are very prominent, with headache, pain, and fatigue of the eyes. Many people complain that they have not had enough sleep, although some of them sleep from eight to twelve hours. With all the evidence at hand, I feel that sleep, instead of being a rest to eyestrain, is too often a cause.

A matter of great importance is the prevention of eyestrain during sleep. Some patients are materially benefited by practicing the **long swing for five or ten minutes just before retiring**. Others enjoy an increased relief from eyestrain by **palming in bed until they fall asleep**.

## EYE-SHADES

(No Sunglasses, Tinted Lenses, UV Blocking Lenses...)

When the eyes are hypersensitive to light, one usually obtains immediate relief from the discomfort by the use of an eye-shade. This relief, however, is temporary, and very soon glasses are prescribed which seldom are a permanent benefit. The conditions are not favorable for normal vision when using eye-shades.

The normal eye is not made uncomfortable in a good light. An eye-shade makes the eyes more sensitive to light and causes eyestrain. Patients who have used eye-shades habitually, are very difficult to cure. Sun treatment, when used properly, is often followed by quick relief. The patient sits in the sun facing the strong light with the eyelids closed. The head should be moved slowly from side to side. At first there may be slight discomfort which usually disappears in a few minutes. Continue for half an hour or longer. Now turn the back to the sun and open the eyes. There should be relief at once. By repetition the benefit becomes greater and more permanent. Do not be in a hurry to look in the neighborhood of the sun. The strong glare may cause a temporary loss of vision, and other discomforts which may continue for some hours or days before recovery. There is no danger of a permanent loss of vision by looking more or less directly at the sun.

(Modern teachers advise closed eye sunning only due to depletion of the earth's ozone layer. Others state it is ok to look near the sun at the bright sky. The head is moved continually left and right to avoid concentration of the sun on any one area of the skin, eyes/sunburn.)

## THE BLACK BANDAGE

Many people desire to sleep late in the morning without being wakened by the sun. Before retiring they cover the eyes with a black bandage, which is worn until late in the morning. Patients who have used it for some weeks or months acquire a great sensitiveness to ordinary light, lose their good vision for distant letters or other objects, and become unable to read even large print without severe pain, headaches and fatigue. The cure of these cases is exceedingly difficult. Eyeglasses, sunglasses, eyeshades impair melatonin hormone production and the sleep cycle.

## SUMMARY

It has been demonstrated that the normal eye has normal sight only under favorable conditions, and the conditions favorable to some are not necessarily favorable to all.

**Stories From The Clinic**  
**No. 68: How Others Help**  
 By Emily C. Llerman

Many reports have been received from those students of Dr. Bates who are conducting clinics. It is encouraging to know that this work is spreading so fast. Clinics are being formed not only in America, but in Europe as well, and our representatives deserve the highest praise for their faithful work. A number of patients have taken a course from Dr. Bates, or myself, so they could teach others how to obtain normal vision. Mothers find it a great help to study the Bates Method. Some of them bring one of their children for treatment, and when they see the child obtain normal sight, they become eager to learn how to cure other members of their family. In this way the work has spread. If we could have a Bates Clinic in every town and city, people would be very much benefited.

There are many patients out West, who are treating the poor without any compensation whatever. They may not have regular clinics, but it is clinic work just the same. We have over fifty patients in Cleveland, Ohio, and some of them are helping the poor there. A teacher in one of the public schools has cured many of her little charges who had defective sight. In her reports to Dr. Bates, she mentioned several cases of defective minds that she had benefited by palming, blinking and swinging. After a number of her pupils were relieved of mind strain, they were placed in regular classes.

This teacher had to be careful not to offend the authorities or to mention that she was using any system or method. She had the pupils practice for a few minutes every day in her classroom. She can appreciate eye education and common sense, because she is a cured patient.

A few grateful patients, well-known women of Cleveland, go about from place to place, helping unfortunate people who have imperfect sight. While I was visiting at the home of Mrs. H. D. Messick, I discovered that she was conducting regular clinic sessions in her home every week. Although she is a busy woman, she gives part of her time to treating patients who cannot come to Dr. Bates. She has done remarkably well with many difficult cases, some of which I would like to report:

A little girl, nine years old, had **convergent squint** of her left eye. Very little of the iris was visible when I first met her. I was surprised when I saw her again, about six months later. The left eye was almost as straight as the right, and her vision had improved to 10/10 at times, with Mrs. Messick's help.

A woman, with **atrophy of the optic nerve of the right eye**, and **myopia** in the left, was first examined by me, December, 1924. Her face was lined with pain, and she seemed to have no desire to smile. The right eye was nearly blind, and she could not see letters of the test card at any distance with that eye. Her vision was about 10/50 with the left eye.

She was directed to palm for about five minutes or longer, and then stand and swing her body from side to side, with a slow, easy sway. The vision of her left eye improved to 10/30, and she flashed the large C of the test card with her right eye. She was advised not to wear her glasses again, and to practice regularly every day. Mrs. Messick's efforts in helping this woman were certainly not in vain.

The last report I received was most encouraging, and ought to be so to any patient afflicted as this woman was. The vision of her right eye is now 8/40, and the left eye is, I believe, normal. However, she reads quite a little (lot) with comfort, and does not complain of pain any more. Her facial expression has changed for the better, and she is very grateful for what has been accomplished.

Another case that I started about the same time, was that of a fifteen-year-old boy, who was wearing glasses for **myopia**. His **left eye was almost blind**, and the vision of the right was 10/30. I taught him to palm and swing, and in less than half an hour his vision became normal, or 10/10 in the right eye. When he covered his right eye, the vision of his left began to improve for the large letters of the card, although they were not clear or distinct. I told him that if he wished to be cured, he would have to practice faithfully every day, as he was directed. He promised to do his part. I just gave him a start, but it was Mrs. Messick who cured him. I visited him some months later, and found his vision normal when he read the test card with each eye separately. He sees as well with the left eye as he does with the right. He displayed some marvelous drawings of ships, which were done after he was cured. The letter I recently received from him is printed below:

August 26, 1925.

My dear Mrs. Llerman:

I am so grateful to you and Mrs. Messick for having helped me to follow Dr. Bates' method, that I am writing to tell of my experience with my eyes.

About December, 1924, we were examined by the school doctor. He told me my left eye was nearly blind.

Mother immediately took me to a well-known oculist in Cleveland, and after several visits to his office, he prescribed glasses for me, to be worn always. A week had passed when I met you at Mrs. Messick's. You told me to discard my glasses and practice palming and swinging, which I gladly did.

Some of the teachers knowing I had worn glasses and seeing that I didn't after I had met you, tried to persuade me to wear them; but I wouldn't, when I noticed how my eyesight was improving.

After seeing Mrs. Messick once a week, and practicing regularly at home five minutes in the morning and five in the evening, my left eye gradually improved to normal.

With deep gratitude for being spared the great annoyance of wearing glasses, I am

Yours sincerely,  
 Mac.

## THE MOVIE MIND

By Jane June

Editor's Note. - The remarkable results obtained by palming are due to the relaxation produced. If a patient will allow his mind to relax, his eyes will be rested and his vision improved. There are many pleasant ways to palm and each patient has his own favorite method. Jane June's idea is very effective.

When I want to see a picture,  
I never need to go  
Into a picture-show of any kind.  
I've a button in my brain.  
I can press it without pain  
And release my movie mind.

Anything I've read or seen  
Flashes quickly on the screen;  
Be it near or far away-  
This is what I've seen today:

Out upon the Naples Bay,  
White sails softly dip and sway.  
The sun is shining clear,  
And those ships seem very near,  
Although so far away.

Just outside the window-pane,  
Which is bright with drops of rain,  
There's a robin hopping fast,  
For his dinner-time is past;  
His head is cock-a-pie  
Because he thinks he hears a worm  
Crawling underneath the grass.

The brown dog, Nether, is after the cat,  
Running hard, though he is fat.  
The cat, as mad as mad can be,  
Is making for the nearest tree.  
When she gets up into that,  
Nether, out of breath and feeling flat,  
Will have to sit down there below,  
Bark offensively-and go.

Oh! there goes a crocodile,  
Swimming down the yellow Nile;  
Just above him, on a vine,  
Feeling very safe and fine,  
Swings a monkey-one of nine.  
Crocodile says, "Come lower, please."  
Monkey says, "I prefer trees,"  
And begins to upward climb.

Just you try and you will find  
Great fun with your movie mind.

Using, improving the memory and imagination improves function of the brain with the eyes, mental, visual pictures and clarity of vision. Practice this method with palming.

## Better Eyesight League Notice

The President of the better Eyesight League has requested us to publish the address of their new meeting place.  
This is:  
Carnegie Hall, Room 810, Entrance on 7<sup>th</sup> Avenue, corner 56<sup>th</sup> street.  
The October meeting will be held on the first Tuesday, the 6<sup>th</sup>, at 8 P.M.

## THE BLIND MAN

### Little Girls Cure Homeless Man of Blindness

Editor's Note. - This letter from a school teacher was just received, and seemed so worthwhile that we decided to make room for it in this issue. It substantiates Ms. Lierman's reports that those who know the method can improve the sight of others. We regret that we did not have time to obtain the permission of the writer to publish this article, and are therefore withholding her name.

Dear Dr. Bates:

I cannot resist telling you what my little Edith Collins, aged twelve years, has done for a blind man that she picked up on the street.

His eyes were very much sunken. She taught him to palm and sun-gaze. She and a little girl friend visited him in his hovel once or twice a week. Much of the time he was so ill that he kept to his bed, but had this so placed that the sun shone on his eyes. Little by little his eyes came forward. He palmed faithfully and swung a chart that was given to him. A visiting nurse was telling him it was all "bunk" one day, as Edith entered. She spoke to the nurse and informed her it was not bunk, and that if she (the nurse) would come back in two or three months she would find out for herself.

Well, up to July the reports were that he was gradually looking better, and his eyes seemed fuller. When school opened, Edith came into my room and said, "He sees!"

I had forgotten about the man, and for a minute I wondered what she meant. She told me that she had met this man on the street a week or two ago - he was very happy - sees to get around, can read headlines in the papers, and can pick out the smaller words in spots. He has promised her that he will not stop exercising till he obtains perfect sight. He also told Edith that if he had not met her, he would still be a blind man begging for food.

Now he intends to find work in some other city. Isn't this a **wonderful thing for a little girl to do**? Of course, if it were not for Edith, the man would still have been blind. Children do not discriminate as to whether a man is a beggar, a worker or worthy. To them there are no differences. They scatter the good into every nook and cranny, and what is more, if it had not been for the revolutionary discovery of this very, very natural way to see and think, I would not have been able to have carried it on to the children, who so unquestionably take to the truth when presented to them.

I have been so excited about this that I had to write you at once!

Two little girls that learnt the Bates Method, obtained clear eyesight teach the Bates Method to a blind homeless man they found living outside under a bridge.

They cure the blindness, his eyesight and health are restored.

Treatment: Sunning, sunlight, palming, shifting and switching on letters on identical close and distant eye charts, swinging, central fixation... Children are often the best Natural Vision improvement teachers.

His blindness cured, he now reads the newspaper, walks the city on his own, looks for a job and continues to practice the Bates Method.

## Soon To Be Published

We wish to announce that Mrs. Lierman's book- **STORIES FROM THE CLINIC** - is now at press, and we hope to receive it some time in December. No definite date could be set heretofore, as Mrs. Lierman's work with Dr. Bates prevented her from devoting much time to writing. As assistant to Dr. Bates, Mrs. Lierman is exceptionally well qualified to place this method before the public. Stories From The Clinic are included in Better Eyesight Magazines. Some of the stories are a bit different in Mrs. Lierman's book. This book is included in the book; Do It Yourself - Natural Eyesight Improvement - Original and Modern Bates Method. Book/Website: [www.clearvisioninfo.com](http://www.clearvisioninfo.com)

## THE BAT

By George M. Guild

When the city boarders occupied all the rooms and beds of the farm house, little Jimmie was sent to the barn to sleep in the hay. At first the change from the house to the barn was a benefit, but in a few days swarms of mosquitoes invaded the place, and tortured Jimmie. Then The Bat appeared. He was such a homely bat, and has such dreadful habits that he annoyed Jimmie very much. The second night he came, again, very much increased in size, with the same wicked little eyes, and apparently full of plans to annoy Jimmie further. Jimmie grabbed a pitchfork, and rushed at The Bat to kill him, not just dead, but very much dead, more dead than any bat had ever been. Before Jimmie reached him, The Bat said, "Have a mosquito?" Jimmie stopped, amazed, and lowered his pitchfork. While he watched, The Bat leaned forward, and dropped a mess of big fat mosquitoes into Jimmie's hands. When Jimmie threw them down in disgust, The Bat looked surprised, because he could not understand how anyone could throw away such a delicacy. He explained to Jimmie that they had a wonderful flavor of sweet flowers and wild honey, and that he was the special Mosquito Catcher to the Fairy Queen. He supplied all the festivals with the choicest mosquitoes.

Jimmie was tired, lay down on his bed of straw, and was immediately fast asleep. He was so grateful to The Bat for clearing the barn of these little pests. Suddenly, he remembered that he had not seen his little crippled playmate for three days, and he became worried. The more he thought of her, the more restless he became. He cried out "Where is my little crippled blind girl? I want to see her. I want the fairies to help her, because she has such beautiful eyes. She is good and kind, but she is crippled, and her beautiful eyes cannot see. Take me to her Mr. Bat, quick, right away."

The Bat picked little Jimmie up, and flew with him, far away, over mountains, rivers, and woods, and stopped in front of a tiny little cottage, on the shore of a big gloomy lake.

How did The Bat do it? Easy enough. The Fairy Queen touched him with her wand, and he became large and strong enough to carry Jimmie.

Jimmie hopped off The Bat's back, and looked through the window of the cottage. He saw nothing but a little bare room. Soon a little old witch woman, with a sharp pointed hat, and a broom under her arm, walked towards the front door, which The Bat was holding tight shut. The Fairy Queen softly alighted on Jimmie's shoulder, and told him many things. "First," she said, "do not ask questions. The witch is trying to steal the little blind girl, and as long as you do not speak, we can manage her. She is really afraid of The Bat, who threatened to fatten his new mosquitoes on her flesh. I do not want any of the mosquitoes filled with the witch's poison blood at all."

Jimmie listened to all the Fairy Queen told him. Soon the Witch became suspicious, and rushed out, straddled her broom, and went sailing toward the sky. Jimmie could not keep still, and called after the old woman as loud as he could: "Goodbye, you old witch!" She heard this, turned back in a rage, and flew straight for Jimmie's face. But The Bat was not idle. He placed himself between Jimmie and the old witch, grabbed her by the neck, threw her to the ground, and swept her with her own broom right towards the lake. When she realized where she was going, she knew she was doomed. She fought back, but The Bat was too strong for her, and in spite of all her efforts she could not stop him. How she did scream, curse and swear. Then she began to cry and beg for mercy, but The Bat kept right on until he swept her into the lake. She slowly sank and finally disappeared. The Bat threw her broom into the water, where it floated on the surface for a few minutes. Suddenly a long, skinny arm, with sharp claws for hands, shot out of the water, grabbed the broom, pulled it beneath the water, and that was the end of the witch.

A company of fairies on the shore of the lake were singing:

"And there she will stay  
Ten years and a day—  
Good Riddance!"

They all now returned to the cottage to look after the crippled blind girl. She was so glad to hear Jimmie's voice, and thanked them all for saving her from the witch.

The Bat, who was now larger than Jimmie twice over, and strong as a horse, was not satisfied with himself. After much coaxing, the Fairy Queen finally found out that The Bat believed he was too homely and wished to be beautiful. While Jimmie was busy with the crippled blind girl, treating her as advised by the Fairy Queen to cure her, The Bat and the Fairy Queen disappeared. Jimmie did help the little girl and they were playing in the woods, having a most glorious time, for she was not now a crippled blind girl, but one who was cured by the fairies, by The Bat, and by the love of Jimmie. Suddenly the little girl cried out:

"See the beautiful butterfly! It is the biggest that ever was, and on its back is the Fairy Queen!" She clapped her hands with glee and ran to the butterfly. The only way the Fairy Queen could make The Bat beautiful was to turn him into a large butterfly. How proud he was of his beautiful colorings and his soft, silky wings. The admiration of the little girl rewarded him for all his goodness.

It is very difficult to get a boy awake and out of bed sometimes. The hired girl had been working over Jimmy to waken him, but all she could get him to say was:

"Just a few more mosquitoes browned in the pan."

## ATTENTION!

The month of October has been set aside as a special "Better Eyesight Month." Complimentary copies of reprints, Better Eyesight Magazines, and other information will be sent on request. Subscribers and patrons will be notified of additional reductions, during this month only, on our literature and publications.

All issues of BETTER EYESIGHT containing articles on Myopia (near sight) are out of stock. We are opening the BETTER EYESIGHT MONTH with reduced prices on reprints dealing with this common eye trouble. Three other popular reprints have been included in this list:

30

### THE FOLLOWING PRICES PREVAIL ONLY DURING MONTH OF OCTOBER:

#### 1.—CAUSE OF MYOPIA

Bates—Reprinted from the M. Y. Medical Journal. 15c.

Two-page pamphlet containing illustrations, demonstrating that Myopia is curable without glasses.

#### 2.—THE PREVENTION OF MYOPIA IN SCHOOL CHILDREN

Bates—M. Y. Medical Journal. 15c.

Children lower their vision when they are nervous, when they strain, squint or perspire. These symptoms may develop into serious defects as the child grows older, if they are not corrected. Defective vision can be prevented or cured by following a few simple rules. These are explained in this reprint.

An important feature, also, is a synopsis of the proper use of the test card, and its benefits in the classroom and at home.

#### 3.—A STUDY OF THE IMAGINATION

Bates—Allied Medical Journal. 50c.

We particularly call this article to the attention of those of our readers who have disregarded the importance of this phase of Dr. Bates' method. We had that many people think the imagination is another form of auto-suggestion. This is not so. When correctly applied to Dr. Bates' method, especially in painting, the imagination produces greater relaxation.

This is the best paper Dr. Bates has written on the subject, and we strongly recommend it. The following defects are also discussed: Polyopia (double-vision), Nyctagmia (moving eyeball), Photophobia (light sensitiveness) and Refractive Pigmentations.

#### 4.—NEW WAYS TO NORMAL VISION

By C. B. Price, M.B.E., F.R.C.S.

Reprinted from the "Herald of the Star." 20c.

Written by a student of Dr. Bates who has a thorough knowledge of the subject. It was written for the layman, from a layman's point of view, with a knowledge of the scientific value of the method. Some of the titles included are: STRAIN AND RELAXATION—PAIN—MEMORY—FINE PRINT FREYBIOPIA (old age sight), and a chapter on the danger and inconvenience of GLASSES.

#### 5.—THROW AWAY YOUR GLASSES

Bates—Hearst's International Magazine. 25c.

At the special request of the editor, Mr. Norman Hapgood, Dr. Bates wrote a detailed explanation of his method. He kept in mind the fact that the article would be read by the general public, many of whom had never heard of his method.

This booklet contains fifteen pages, five of which are entirely devoted to treatment.

THROW AWAY YOUR GLASSES is especially adapted to beginners, those who wish further information on this method, or those practicing at home.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

NOVEMBER, 1925

### MOVING

The world moves. Let it move. People are moving all day long. It is normal, right, proper that they should move. Just try to keep your head, or one finger, one toe, stationary, or keep your eyes open continuously. If you try to stare at a small letter or a part of it without blinking, note what happens. Most people who have tried it discover that the mind wanders, the vision becomes less, pain and fatigue are produced.

Stand facing a window and note the relative position of a curtain cord to the background. Take a long step to the right. Observe that the background has become different. Now take a long step to the left. The background has changed again. Avoid regarding the curtain cord. While moving from side to side, it is possible to imagine the cord moving in the opposite direction. By practice one becomes able to imagine stationary objects not seen to be moving as continuously, as easily, as objects in the field of vision.

Seeing objects at different distances move opposite each other improves relaxation, eye movement and the clarity of vision. It also helps people with very unclear vision distinguish one object from another object, improves the ability to look at and shift part to part on one object at a time. This improves shifting with central fixation which further improves the clarity of vision.

The speed of the movement of close and distant objects changes if the eyes look at close or distant objects when moving left and right. Normally when practicing moving left and right the eyes do not look at any objects - just let the eyes move along, pass by over objects in the visual field.

**Universal Swing:** When one becomes able to imagine all objects seen, remembered, or imagined, to be moving with a slow short, easy swing, this is called the Universal Swing. It is a very desirable thing to have, because when it is imagined with the eyes closed or open, one cannot simultaneously imagine pain, fatigue, or imperfect sight.

The universal swing can be obtained without one being conspicuous. With the hand covered, **move the thumb from side to side about one-quarter of an inch, and move the eyes with the thumb.** Stationary objects can be imagined to be moving.

When walking rapidly forward, the floor or the sidewalk appears to move backward. It is well to be conscious of this imagined movement.

Never imagine stationary objects to be stationary. To do this, is a strain, a strain which lowers the vision.

### CENTRAL FIXATION

By W. H. Bates, M.D.

**Central Fixation:** *The letter or part of the letter regarded is always seen best.*

With normal vision, a letter or an object cannot be seen clearly or perfectly unless one sees a part of the letter or object best, or better than all other parts.

Central fixation is passive. We do not see by any effort. Things are seen, one part best. Furthermore, it is a condition of relaxation of the eye or mind obtained without any effort.

The normal eye with normal sight is always at rest. Nothing is done. No effort is made. **Many cases of imperfect sight have been cured when no efforts were made to see.** One cannot relax by working hard, straining, nor obtain rest of the eyes or mind by the help of a strain. When the eyes are normal, they are at rest. When they are imperfect, they are always under a strain.

**+Central fixation should not be confused with concentration, which is defined by the dictionary to mean an effort to keep the eyes or mind continuously on one point only, and to ignore all other points.**

Try it. Look directly, for example, at the point of the notch on the upper right corner of the large letter C on the Snellen test card. Keep the eyes open without blinking. In a few seconds, or part of a minute, the mind begins to tire from the monotony. An effort is made to hold the concentration. The effort increases with discomfort or Pain. The vision becomes less, the white of the notch looks gray, the black appears less black, less clear and less distinct. The notch regarded is not seen as well as other parts of the large letter not regarded, and Central Fixation is lost. Not only does the notch appear less clear, but by continuing the effort the large letter C, as well as all the letters on the card, are seen less and less perfectly. The white of the whole card is also modified and becomes less white. Other objects in the neighborhood of the Snellen card soon begin to blur and are seen imperfectly. The stare or strain has very much the same effect as if the sun were covered with a cloud or as if the light in the room, or the general illumination, were lessened. When central fixation is practiced, all the objects in the room, including the Snellen card, look brighter, clearer, just as though the light had increased.

Hang a ruler or curtain cord in front of an open window with a view of distant objects.

Rock left and right in front of the window. Body, head, eyes move together, at the same time, in the same direction.

See the cord appear to move opposite the movement of the body, head, eyes while distant objects appear to move with the body, head, eyes in the same direction.

The cord and distant objects move against each other in opposite directions.

Move the thumb side to side 1/4 inch or, do the thumb on finger tip movement as described in previous chapters. Move the eyes with the thumb. Imagine stationary objects moving, 'the swing' when the eyes shift.

Shift point to point (dot to dot) on the E seeing one small part (dot) clearest at a time in the center of the visual field. The central field moves with the eyes as the eyes shift dot to dot.

Stare at the point on the upper right notch of the C. Do not shift the eyes, eyes immobile, do not blink. Strain, tension, blur occurs. Now shift on the C part to part and experience relaxation and clear vision.

Remember and see the pillow clear with central fixation and shifting: Look at and see one corner of the pillow best at a time. Shift from corner to corner (dot to dot) seeing one corner at a time best, clearest in the center of the visual field. Shift part to part on any area of the pillow. The pillow is seen clear.

Experience the cause of unclear vision; staring, not blinking, not shifting, eccentric fixation, trying hard, using effort to see clear. Learn to avoid this. Learn to use the eyes correct; relaxation, no effort, shifting, blinking, central fixation and the vision is clear.

+Concentration is trying to see one thing only. It always fails.

+Central fixation is seeing one thing best, and all other objects not so well.

Central fixation is combined with shifting; the eyes, center of the visual field, shifts, moves continually from point to point; part to part, object to object.

When the vision, memory, or imagination are imperfect, concentration can always be demonstrated.

When the vision, memory, or imagination are perfect, Central Fixation can always be demonstrated.

Central fixation is an illusion. All parts of small letters as well as large ones are printed with the same amount of blackness. We do not see illusions. They are only imagined. When we see best one part of a letter, or other object regarded, we think we see it best, or more accurately, we imagine it best. One can imagine anything desired, and much more easily than to make an effort to see it. This fact should be demonstrated repeatedly, and consciously, until it becomes an unconscious habit.

With the **eyes closed the imagination of Central Fixation may be much better than with the eyes open. By alternating the imagination of Central Fixation with the eyes open and closed, both may improve.**

Many persons have no mental pictures with their eyes closed. For example: A patient consulted me about his eyes. He was asked to look at a white pillow. "Can you see it?" he was asked.

"Yes," he answered.

"Now, close your eyes. Can you remember it?"

"No," he replied; "I remember a black pillow."

"With your eyes open, can you see one corner of the pillow best, and the other corners not regarded worse?"

He was able to demonstrate this fact, and that he could in turn see, or imagine, each corner regarded best and the other corners worse. With his eyes closed he was able to remember one corner at a time best, and when he remembers the pillow by Central Fixation, he obtained a mental picture of a white pillow almost as well as he could see it with his eyes open.

He was then asked to remember two corners simultaneously, both perfectly clear. At once he lost his mental picture of the pillow. He demonstrated with other objects as well that he could only remember or imagine mental pictures of them by Central fixation.

Another patient had suffered for many years with almost constant pain and fatigue. With his eyes open his vision was 20/20. He read diamond type as close as six inches, and as far off as twenty inches. He could imagine the white part of large or small letters whiter than the rest of the Snellen test card, but only with his eyes open when regarding the letters. With his eyes closed he could not remember mental pictures of any objects.

He was asked: "Which is whiter, the white center of a large letter of the Snellen card or the white snow on the top of a mountain?" He answered, "The white snow on the top of a mountain."

"Can you shift from one mountain top to another, remembering each one best and the others not so well, or worse?"

This also he was able to do. But when he tried to imagine two or more snow-capped mountains simultaneously, he at once was conscious of an effort and lost his imagination of his mental pictures of the snow.

The memory of the snow-capped mountains by Central Fixation helped him to imagine Central Fixation with his eyes open as well as closed.

A girl, age eight, had imperfect sight not corrected by glasses. The right eye turned in continuously. The vision of this eye was 3/200 with glasses. The left vision was one-half of the normal. She was taught Central Fixation and became able, in a few days, to imagine one part best of the larger letters. The vision of both eyes improved very much. She demonstrated the value of Central Fixation, and that she could not distinguish clearly even the large letters with each eye unless she imagined one part best. By repeated demonstrations this young patient **acquired speed in the practice of Central Fixation**. She became able to read a newspaper more than five feet from her eyes by artificial light. Fine print, or diamond type, was read rapidly, easily, at one inch from each eye.

She enjoyed the practice of conscious Central Fixation. It was to me very wonderful to observe her imagine very small letters by Central Fixation and read them at ten feet or further.

The squint disappeared permanently.

A girl, aged twelve, was treated for progressive myopia. The vision of each eye was 3/200. With concave 16D.S. the sight of each eye was improved to 20/70. The patient was very nervous. Her memory was poor, and she was behind in her schoolwork. Treatment with the aid of **Palming** and **Central Fixation** improved her vision slowly. After about six months there came a sudden change for the better. In one day, **her vision improved from 10/200 to 10/10 plus**. The next day she read the bottom line of each of three strange cards at twenty feet. It was remarkable, also, because she read all the letters as rapidly as she could pronounce them. The mother was worried because her **daughter had suddenly acquired a habit of running down stairs three steps at a time**. She had never stumbled or fallen once. The mother also reported that the patient had acquired much pleasure in coasting and was the most daring of all the children. Her scholarship had improved. The teacher said the patient would read a page of history in a few seconds, and recite it with **a perfect memory** after a few days, a month, or longer. Her memory for other subjects was equally as good.

Immediately after she read the strange cards with normal vision, I asked her: "What helped you?"

"Starch," she answered.

Then she explained that she had become able to imagine a small piece of white starch perfectly white by Central Fixation. **When her imagination was perfect her myopia disappeared**, her eyes were normal, which made it possible to obtain normal vision. The retinoscope used at the same time demonstrated that her myopia disappeared when she had a perfect imagination of Central Fixation.

Patients whose sight is very imperfect usually require a much longer time to acquire Central Fixation than do some others. One should not be discouraged when, after some weeks or many months, their vision remains imperfect. Too many are disappointed because they fail to obtain Central Fixation after long periods of time, practicing without the help of a competent teacher. One very determined patient devoted many hours daily for over a year without any apparent benefit whatever. She told me that she knew she was curable and was resolved to keep at it the rest of her life if necessary. I wrote her a few suggestions. She followed my advice

and was cured in a week.

## STORIES FROM THE CLINIC

### No. 69: Aunt Mary

By Emily C. Lierman

For a year I have been treating a woman, **aged sixty-eight**, who has **cataract in both eyes**. In the beginning I saw her about once a week, then later I treated her less frequently because I had so little time. She lives with her sister and family in the country, and everyone who knows her calls her Aunt Mary. She has all the reason in the world to be depressed or unhappy, because with the exception of just a few years, she has been a cripple all of her life. Yet Aunt Mary greets you with a smile and makes you understand that she is happy.

A few years ago her sight began to trouble her, and she was examined by an eye specialist. He said that cataract was beginning to form in each eye and that nothing could be done until they became ripe, when she was to be taken to the hospital for an operation. Then I was consulted by her family and asked to call at her home and examine her eyes. With the retinoscope, I saw a clear, red reflex in the right eye, but none in the left. It was evident that her trouble was caused by strain, and her condition was becoming worse because she worried about the outcome.

We placed her in a comfortable chair in the garden where the sun was shining and fastened a white test card on the trunk of a tree. As she looked at the card, she began to squint, because the bright light bothered her. Teaching her to blink often, helped her to look at the card with less discomfort. She could read 10/200 with the right eye and 1/200 with the left, which means that at ten feet the only letter she could see with the right eye was the large letter C on the top of the card, and with the left eye she could not see it further than one foot. With some difficulty, Aunt Mary was able to raise one of her arms, so that she could cover her eyes with her palm. She had a good imagination, so while her eyes were covered, we talked about various kinds of flowers she had seen. We also talked of white clouds and a blue sky. As I mentioned one object after another, her mind did not dwell on one thing very long. I spent about an hour with her the first day, and her vision in that time improved to 10/40 with the right eye and 10/200 with the left, **improving her imagination of things she had seen, with eyes closed as well as with them open**, was the only method I used that day.

There was quite an improvement in her eyes when I saw her again. The vision of her right eye improved to 10/30 and 10/70 in the left. It was impossible for her to stand and swing, so I placed myself before her in an arm chair and moved my body and head to the right and then to the left with a slow movement, and asked her to do the same. While we were doing this, I could not understand why she did not see or imagine things about her moving opposite to the direction in which her head and eyes were moving. Then I noticed that she was staring while trying to follow my directions, even though she was blinking. It did not take her very long to learn how to shift her eyes and after that she made steady progress.

Dr. Bates became interested in Aunt Mary's case and offered to call with me the next time I treated her. He examined her eyes with his ophthalmoscope and said there was not enough opacity of either lens to lower the vision. She was very much encouraged when Dr. Bates told her that her cataract had improved. He also remarked about her cheery disposition, and how her faithfulness in keeping up her daily treatment would help greatly in the cure of her eyes.

There is an enclosed porch where she practices on rainy days or when it becomes too cold to sit in the garden. Her loving family do all they possibly can to make her comfortable, so there is every chance that she will be cured of her eye trouble.

Aunt Mary did not like to practice with the white C card, because the white background bothered her and made her strain. She likes to practice with the white letter card on a black background, so we use the black card mostly during treatment. In her sunny room hangs a picture which is beautifully colored, but she could not see it clearly. She explained that it seemed to be in a mist always. I gave her fine print to practice with, and she has become able to read it in a fairly good light at six inches from her eyes.

Her confidence in me makes me all the more anxious to cure her. In the last few months she has realized the fact that no operation for the removal of cataract will ever be necessary if she continues to practice. She surprised me one day by reading 10/20 with both eyes, and after sun treatment she read 10/15. Surely, at this time, if her cataracts were as bad as they were in the beginning, when I first saw her, her vision would not have improved, neither would she have responded to the sun treatment. Recently I examined her again with the retinoscope, and I saw a red reflex in the left eye, as well as in the right.

A neighbor, who is twenty years younger than Aunt Mary, and has presbyopia or old-age sight, was surprised to find out that Aunt Mary had better sight than she had. The fact that her vision was better than a woman so much younger made her anxious to practice more. The last time I visited Aunt Mary she read the bottom line of the test card at ten feet, or 10/10 with her right eye, and 10/20 with the left. She reads the fine print now at all times, and also the newspaper and her Bible without any trouble. When she strains to see at the distance, things seem to blur before her eyes, but when she palms and sways her body, as she sits in her chair, the mist clears away and she sees better.

When I first became acquainted with her, I noticed how difficult it was for her to move about with her crutches. To get up from her chair was an effort. Not so long ago, I offered to help her change her position, but she managed very nicely herself and got up with the aid of her crutches without any effort at all. I believe the constant practice of the body swing has not only improved the condition of her eyes, but also her general condition as well.

Aunt Mary shifting on letters on the Eyechart in her garden, in the sunlight. Palming and remembering, imagining the flowers in her garden, clouds in the sky... relaxes her mind, eyes and improves her vision.

## SONNY

By George M. Guild

Sonny was a boy, very much of a boy, a manly boy, large for his age and strong with the strength of youth. He was twelve years old. He loved his mother very much and did all that he could to help her. Sonny enjoyed entertaining other boys and was popular with grown ups as well. His father was very proud of him and frequently talked about his boy to the people he knew. He rather overdid it, and his friends would usually tire of hearing so much about Sonny at home, Sonny at play, Sonny at school, Sonny all the time and every day. His mother was just as proud of her boy and could talk hour after hour about him, if one were polite enough to listen.

There was another member of the family, a sweet young girl, who was sick in bed and who suffered constant pain. She was unable to sit up, and of course unable to walk. Her name was May, and she was eight years old. Recently her sight had become poor, and she was nearly blind. Sonny spent more time with her than one would expect. He invited other boys and girls to visit his sister. He read storybooks to her, all about knights, ladies, kings, queens and the fairies. She liked the fairy stories best of all and wanted very much to see the fairies and talk to them. Sonny was just as anxious as she was to meet the fairies.

One day he went into the flower garden to cry in a place where no one could see him and be annoyed with his tears. May did not seem so well. No one had ever helped her pain, and today she said that her sight was so poor that when she looked at Sonny his face appeared so far away that she could not see it at all. He tried to say something to make her feel better, but his throat had a big lump in it which prevented him from talking. After he had cried for some minutes he felt a little better. One of the flowers seemed more beautiful than any of the others, and while he was looking at this flower it nodded to him and turned into a beautiful fairy. She had bright blue eyes that were full of fun and play. They were kind eyes, too, but mostly they seemed to be laughing all the time. Sonny had never seen eyes which appeared to know so much, to know all there was to know, and to know many things which others did not know, never could know, or would know. Her eyes were indeed full of wisdom.

The fairy danced a few steps, whirled around on her toes, stood still for a moment, bowed low to Sonny, threw him a kiss, and asked a question: "How do you like me?"

"I love you with all my heart," said Sonny.

"Why were you crying?" asked the fairy.

"I was crying because my sister is sick and becoming blind. No one has helped her. No one can help her."

"Would you like the fairies to help you?"

"I certainly would," he answered.

Thereupon the fairy blew a gold whistle. In a few minutes the fairies began to arrive. At first slowly, by twos and threes, and then in larger numbers more rapidly. They soon filled the garden. They found places on the lawn, the trees and the outside of the house. They were not silent fairies by any means. It seemed as though all were talking, laughing and singing. Furthermore, they were not still for a moment. Their heads and eyes were always moving in time with their dancing feet. Those people who have seen fairies dancing have said that it is all very wonderful, beautiful and delightful.

Sonny was in a great hurry to have his sister and the fairies meet. He learned that the first fairy he met was the Queen and beloved very much by all the other fairies. As soon as the fairy Queen met May, she directed the child's mother to lift her from the bed, holding her very gently. **Then the mother was told to sway her sick child from side to side, slowly at first, and then more vigorously, but always easily and gently. When done properly, it cured dizziness and many other things.**

The fairy Queen insisted that the patient should not see things moving when her head and eyes were moving, but that she should **make believe or imagine that she saw stationary objects to be moving in the direction opposite to the movement of her head and eyes.**

May was a good pupil. When her mother swayed her whole body from side to side, she soon became able to imagine the room, the bed and other stationary objects to be moving. The movement did her good. She smiled up to her mother and said: "Mother, dear, the pain in my back is all gone, and I can now see very much better."

The mother kept on swaying the patient from side to side, while May imagined that all the objects she was not regarding were apparently moving from side to side all the time. When the mother tired after half an hour or longer, Sonny took his sister in his arms and continued the swaying. They alternated and continued the swaying for several hours. All this time the fairies were dancing and singing where May could see them. She enjoyed it all and tried to sing the song of the fairies as well as she could, keeping time with their singing.

The Fairy Queen now directed the child to sit up in bed and at first sway herself with the help of her mother and Sonny and gradually do it all without their help. She soon became able to do it alone. Her strength increased rapidly, while her sight also became much better.

The Fairy Queen then advised that she stand on the floor with the help of her mother and Sonny. Her strength continued to improve until, much to the delight of all, she became able to sway herself without any help. Sonny was so happy with her wonderful improvement that he laughed and shouted for joy, while all his mother could do was to smile as the tears flowed from her eyes.

When Sonny's father came home he watched the proceedings approvingly. He did not believe in fairies, consequently he did not see them dancing nor hear them singing. He stood in a corner of the room blowing his nose frequently, although he had no cold. His daughter soon saw him and, without stopping her swaying, threw him a kiss and called out to him:

"Oh, father, my pain is all gone; I can stand on my feet; I can walk. I can see you perfectly; the fairies have cured me. I am perfectly happy. Aren't you glad?"

But he could not speak. He felt so weak that he had to sit down on the edge of the bed. His wife took his hand. She could not speak, either. She just smiled, while her tears continued to flow.

Sonny had lost all control of himself. He shouted; he alternately laughed and cried. He danced around the room. He hugged his father, his mother, the neighbors who came to see the wonderful cure by the fairies. They had to take him to another room, where he flung himself down on a bed, buried his face in a pillow and sobbed as though his heart would break, because he was so happy. The next morning his sister walked into his room and wakened him with a kiss. She smiled and said: "Good morning, Sonny."

## THE LIGHT TREATMENT

Sunlight and Sunglass

By M. A. Crane

**People who live in the dark and seldom or never see the sun, like miners, for example, always have something wrong with their eyes.**

In the tenement houses where the light is poor many children acquire a dislike for the sunlight. They will bury their faces in a pillow and shut out all light. Too many of them are brought to a Clinic with **ulcers on the front part of the eyeball**. Treatment with antiseptic eyedrops and other measures generally fail to cure. Sending them out of doors in the bright sunlight has been followed by complete relief.

One patient, a man with serious disease of his eyes, had spent much time in a hospital where his eyes were protected from the light by the use of bandages. After some months, his eyes had not improved, and he left the hospital wearing very dark glasses for protection from the light. His eyes became more and more sensitive, although the dark glasses were changed frequently to those that were darker, until he finally wore the darkest glasses that he could obtain. Still there was no relief from the sun. Later, the dark glasses were discarded permanently. The sensitiveness to the light became less after he exposed his closed eyelids to the sun for half an hour or longer, moving his head at the same time slowly from side to side.

After the eyes have improved, it may be possible for the patient to look down while some one else gently lifts the upper eyelid toward the brow, exposing some of the white part of the eye above the pupil. At first it may be well to shade the eyes from the sun until the patient acquires sufficient control to look down easily, continuously and without strain. **With the eyes looking far down, one focuses the direct rays of the sun on the exposed white part of the eye, with a strong convex glass, moving the glass continuously to avoid the heat of the condensed sunlight. One needs to caution the patient to avoid looking directly at the sun while the light is being focused on the eye. The results obtained from this method have usually been very gratifying. When the eyes are inflamed from disease of the eyelids, the cornea, the iris, the retina, the optic nerve, from glaucoma and other inflammations, the use of the burning glass (sunglass) has been followed immediately by a lessening of the congestion and a decided improvement in vision.**

Many people ask the question: "How long does it take to obtain a sufficient benefit to be noticeable?" When the sun treatment is employed, the improvement in the sight may be demonstrated in a very short time.

The sun treatment improves the vision of all patients who are wearing glasses for the relief of pain, fatigue, and imperfect sight, no matter what kind of glasses are worn or how strong they may be.

The direct sunlight focused on the white part of the eye is a benefit in many cases of blindness with **hardening of the eyeball (glaucoma)**, or **softening of the eyeball (cyclitis)**, also in cases of **cataract**, and of **opacities in other parts of the eye**. It was interesting to observe the improvement in a large number of patients **blind from scar tissue on the front part of the eye, the cornea**. They were benefited so much that their sight became normal.

### Babies and Sunlight

It is good practice to expose the eyes of babies to the direct sunlight not only when they are awake but also when asleep.

The sunlight treatment has never injured the eye nor lowered the vision permanently in a single patient, even when used improperly.

Patients with **cataract** seem to improve more decidedly from the light treatment than from some other kinds of treatment. Congenital cataract or cataract present from birth, is benefited and often cured in the same way. Cataract produced by an injury to the eye has improved and occasionally been cured by the effect of light on the eye. So often has the light treatment benefited many kinds of cataract that the use of the light is strongly recommended in all cases.

The beneficial effect of light is largely, if not entirely, due to its mental effect. One evidence, that this is true, is the fact that the benefit is so quick that there is not enough time for the eyeball to be improved sufficiently to account for the good result. It has been stated by some authorities on the value of sunlight in the treatment of disease, that it should be used out of doors to obtain the best results, and that after it has passed through glass it has lost much of its healing properties. This may be true in the treatment of tuberculosis, or other diseases, but apparently not when used for the benefit of imperfect sight.

Modern Natural Vision Improvement teachers state that all glass; plain, tinted, ... including eyeglasses block out part of the sun's full light spectrum causing unbalanced light to enter the eyes, and lower eye, brain, body health, function and clarity of vision.

The use of the Sunglass is temporary - it gets the cells, light receptors... in the retina, lens... 'awakened', back to full life, normal health, function. The Sunglass treatment is then discontinued and is replaced by daily exposure to plain, full spectrum sunlight not passing through glass.

Strong sunlight in the tropics is as much, if not a greater relief, as it is in colder countries. Patients who do not wear a hat, or otherwise shield their eyes from the brightness of strong sunlight, have testified that their eyes became much stronger and their vision decidedly improved by the exposure. However, one should first of all accustom the eyes gradually to the light to prevent discomfort.

A hat prevents sunburn, wrinkles, freckles on the face.

The question has often been asked, "Is electric light beneficial?" Electric light is beneficial, but not to the same degree as sunlight. Many people have accustomed their eyes to all kinds of electric light and have improved their vision very materially by using the electric light as intelligently as the sunlight.

The sun is the whitest object there is. Many patients complain that it is not white but red, gray, blue, brown, or some other color. It has been described as black when regarded by patients whose eyes were very sensitive to the light, patients whose vision was very imperfect, or who suffered very much from eyestrain.

**Looking at the sun is quite frequently followed by seeing red, blue, yellow, and other colors for some minutes, hours, days, weeks, or months. These colors always disappear in time.**

**Palming, swinging, the memory of perfect sight, hasten their disappearance.**

The **twinkling stars** owe their peculiar appearance to **good vision alternating with imperfect sight** caused by eyestrain. The planets look bright with a steady light and do not usually twinkle. One can often imagine them to be twinkling with the help of a conscious strain alternating with a frequent rest. Blinking with a strain will quite often produce twinkling of the planets. By practice one can become sufficiently expert to produce twinkling of the moon.

Twinkling Stars can be caused by: fluctuating visual clarity, staring, dim light causing the eyes central field to stop functioning so the eye must look slightly away from the star to see it with the eyes less clear peripheral field, debris on the cornea, eye floaters, objects floating in space across the star.

**Stories From The Clinic**  
**By Emily C. Lierman**

***This valuable book is now in press and we  
expect it to be ready in a few weeks.***

**CENTRAL FIXATION PUBLISHING Co.**

**QUESTIONS AND ANSWERS**

Q- Why is it that many people feel the need of glasses for near work when they reach middle age?

A- When trying to read they strain, which makes the sight imperfect. This may occur before the age of forty or after sixty.

Q- How can I prevent the sun from hurting my eyes?

A- By becoming accustomed to it. See page 15 of this issue of "Better Eyesight." - Sun treatment

Q- When should one blink and under what circumstances should stationary objects be imagined as moving, and for what purpose?

A- One should blink to improve the sight. Stationary objects should be imagined as moving to avoid the stare which always impairs the sight and causes pain and fatigue. Stationary objects appear to move when the eyes move, shift.

Q- When can one determine whether the desired results have been attained in palming?

A- The desired results in palming are obtained when black is seen.

(Modern teachers' state; Desired results are obtained when relaxation of mind, eyes, body is attained. They state that seeing black is not mandatory. It is often easier to just imagine any pleasant thoughts, objects, let the mind drift.)

Q- Will you please tell me if results are obtained at all ages or whether there is a limit? If there is, after what age are results unsatisfactory?

A- Results are obtained satisfactorily at all ages without an exception.

**BETTER EYESIGHT**

**A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES**

**DECEMBER, 1925**

**DIZZINESS**

Dizziness is caused by eyestrain. Some people when standing on the roof of a house looking down, strain their eyes and become dizzy. Usually the dizziness is produced unconsciously. It can be produced consciously, however, by staring or straining to see some distant or near object.

**Some persons when riding in an elevator are always dizzy and may suffer from attacks of imperfect sight with headache, nausea, and other nervous discomforts.** An old lady, age sixty, told me that riding in an elevator always made her dizzy, and produced headaches with pain in her eyes and head. I tested her vision and found it to be normal both for distance and for reading without glasses. To obtain some facts, I rode in an elevator with her from the top to the bottom of the building and back again. I watched her eyes closely and found that she was staring at the floors which appeared to be moving opposite to the movement of the elevator. I asked her the question: "Why do you stare at the floors which appear to be moving by?"

She answered; "I do not like to see them move, and I am trying to correct the illusion by making an effort to keep them stationary. The harder I try, the worse I feel."

I suggested to her that she look at one part of the elevator and looking at the floors. Her discomfort was at once relieved, and she was soon cured.

In all cases of dizziness, the stare or strain is always evident. When the stare or strain is relieved or prevented, dizziness does not occur.

With advancing years attacks of dizziness and blindness occur more frequently than in younger individuals. All attacks of dizziness with blindness are quite readily cured by practicing the imagination of the swing, the memory of perfect sight, or by palming.

## SHIFTING

By W. H. Bates, M.D.

*Shifting: The point regarded changes rapidly and continuously.*

A man with imperfect sight, who had obtained normal vision by my method of treatment without glasses, called about five years later and announced that the cure had proved permanent. His vision was normal when each eye was tested at twenty feet with Snellen test cards which he had not seen before.

He was asked, "What cured you?"

"Shifting," he answered.

All persons with imperfect sight make an effort to stare with their eyes immovable. The eyes have not the ability to keep stationary. To look intently at a point continuously is impossible, the eyes will move, the eyelids will blink, and the effort is accompanied by an imperfect vision of the point regarded. In many cases the effort to concentrate on a point often causes headache, pain in the eyes and fatigue.

All persons with normal eyes and normal sight do not concentrate or try to see by any effort. Their eyes are at rest, and, when the eyes are at rest, they are constantly moving. When the eyes move, one is able to imagine all stationary objects in turn to be moving in the direction opposite to the movement of the head and eyes. It is impossible to imagine with equal clearness a number of objects to be moving at the same time, and an effort to do so is a strain which impairs the vision, the memory, or the imagination. To try to do the impossible is a strain, which always lowers the mental efficiency. This fact should be emphasized.

Many patients have difficulty in imagining stationary objects to be moving opposite to the movements of the eyes or head. When riding in a fast moving train, and one regards the telegraph poles or other objects which are seen,—the near objects may appear to be moving opposite to the direction in which the train is moving, while more distant objects may appear to move in the same direction as the train.

The above facts may also be imagined when traveling in an automobile. The driver of the car and others occupying a front seat may imagine the road to be moving toward the moving car. When pain, fatigue or other symptoms are present it always means that the individual is consciously or unconsciously trying to imagine stationary objects are not moving. The effort is a strain.

*Walking and Eye Movement, Oppositional Movement*

When walking about a room, the head and eyes move in the same direction as the body moves, and the carpet and the furniture appear to move in the opposite direction. However, it can be demonstrated that when the head and eyes are moving forward they are also moving from side to side. Every time the right foot is placed forward the eyes move to the right, while stationary objects appear to move in the opposite direction,—to the left; when the left foot steps forward the whole body, including the eyes moves to the left, while stationary objects appear to move in the opposite direction,—to the right.

Patients with normal vision are able to imagine this movement more readily than those with imperfect sight. The head and eyes also move upwards and downwards as the foot is lifted and lowered. When you raise your foot to take a step, the eyes go up, and everything else that is stationary appears to go down. When you lower your foot or head, the eyes go down, and stationary objects appear to go up.

*Shifting*

**Shifting when practiced with the best results is usually unconscious.** Very few people with normal sight, which may be continuous for many years, ever notice that they are constantly shifting correctly. One may shift in a wrong way, strain the eyes, and fail to improve the vision. What is the right way? **The right way to shift is to move the eyes from one point to another slowly, regularly, continuously, restfully, or easily without effort or without trying to see.** The normal eye with normal sight has the habit of always moving or shifting, usually an unconscious habit. **When, by practice, the eye with imperfect sight acquires the conscious habit of shifting, the habit may become unconscious.** When the shifting is done properly, the memory, imagination, mental efficiency, and vision are improved until they become normal.

It often happens that when one consciously or intentionally shifts in the wrong way, a better knowledge of the right way to shift may be obtained. When the eyes are moved to the right, stationary objects should appear to move to the left; and, when the vision is good, all objects not regarded are seen less distinctly than those regarded. When the vision is imperfect, objects not observed may be seen better, or an effort is made to see them better than those directly observed. In fact, it is always true that in all cases of imperfect sight the eyes do not see best where they are looking, and central fixation is lost. To shift properly requires relaxation or rest. To shift improperly and lower the vision requires an effort. When one stares at a point, without blinking or shifting; fatigue, distress, or pain is felt. To continue to stare without shifting is hard work. To see imperfectly is difficult; and, when one regards letters which are blurred or not distinguishable either at the distance,—ten feet or further, or at a near point,—six inches or less, the strain on the eyes can be felt. Imperfect sight or a failure to see requires much trouble and hard work. This fact should be demonstrated repeatedly by the patient until thoroughly convinced that rest of the eyes, mind or body can only be obtained by shifting easily, continuously and without effort.

What is true of sight is also true of the memory and imagination. With the eyes closed, one can imagine that he is looking over the right shoulder for a moment and then shift the imaginary gaze over the left shoulder. By lightly touching the closed eyelids with the tips of the fingers he can feel the eyeballs moving from side to side

From Dr. Bates Better Eyesight Magazine.

Eyes closed. Imagine looking over the left and right shoulders. First do this without moving the head. Then, imagine looking left and right and move the head with the eyes. Move relaxed, easy—look left, then right, left, right... no hurry. Notice the eyes move under the closed eyelids when imagining looking left and right. The brain, memory, imagination, left and right hemispheres... control eye movement. This activity relaxes the eyes, eye muscles, brain, head, neck, activates easy eye movement/shifting and activates, integrates the left and right brain hemispheres.

Eyes closed. Imagine looking over the left and right shoulders. Lightly touch the upper eyelids and feel the eyes move left and right when imagining looking left and right. The brain functions with the eyes.

E

Eyes closed. Imagine shifting left and right on the letter E. See it appear to move side to side opposite the movement of the eyes. Feel the eyes produce smaller movements.

EC

Look at, shift on, see one letter clearest at a time in the center of the visual field. Practice with the eyes open and in the imagination with the eyes closed.

E

Blink—the eyes shift automatically up and down when blinking. Blink and shift in any direction.

when the shifting is done right. It can be done wrong when one, by an effort, imagines the eyeballs stationary under all conditions.

With the eyes closed, one can imagine alternately looking from one side of a letter to the other. When the imagination of the shifting is done right, the letter remembered is imagined to be moving from side to side. Two letters close together may be imagined or remembered clearly, provided one is imagined better than the other, or when the attention is shifted to each alternately without effort or strain.

#### Blinking

Blinking is necessary to maintain normal vision in the normal eye. When blinking is prevented, the eyes become tired and the vision very soon becomes worse. Some persons, without knowing it, will blink five times in one second as demonstrated by the camera. When regarding a large letter of a Snellen test card at twenty feet or one foot, while blinking consciously, the letter appears to move up while the eyelids close slowly, and to move downwards as the eyelids are slowly opened. **This apparent movement is caused by shifting the eyes up and down while blinking.** (Blinking causes the eyes to shift automatically.) Many patients are unable to shift their eyes a short distance with benefit. When blinking, they may fail to obtain relaxation, because they too often blink with an effort. It is possible for most patients to demonstrate that the shifting of the eyes up and down improves the vision, when blinking is done easily, without effort. Blinking is very important. It is not the brief periods of rest obtained from closing the eyes which helps the sight so much as the shifting or movements of the eyes. It should be repeatedly demonstrated that the eyes are only at rest when they are shifting.

#### STORIES FROM THE CLINIC

##### No. 70 - Christmas at the Clinic

By Emily C. Lierman

We had a lively time at the clinic last Christmas. Many poor souls were made happy at that time, because of the generous contributions received throughout the year for the clinic fund.

I still keep up the old custom of telling a Christmas story to my younger patients. Every time they come for treatment, I tell them to palm their eyes, and then I try to improve their memory and imagination, which always improves their sight. It is necessary to remind a child of pleasant things, and what is more wonderful to the child mind than a Christmas tree laden with toys and candies? While I am treating boys and girls at the age of twelve or older, I talk about ice skating or sleigh rides, hills of snow, the pure whiteness of the drifts, or I tell them to imagine they are making snow balls. This helps to improve their vision for the test card and relieves tension or pain. Young men and women who work in shops usually find it a benefit to imagine that objects about them are moving all day. I tell them to blink slowly, but constantly, and shift their eyes while blinking. This stops the stare which causes so much body fatigue. If I have had a hard day, treating the most difficult cases, I find it a great help to palm and remember some of my childhood days. I think back to the night before Christmas. Mothers will find it a great help in improving their own sight if they make a daily habit of spending ten or fifteen minutes with their children, palming and resting. Children can easily form mental pictures while palming, especially remembering the Christmas decorations in store windows, the funny mechanical toys, and animals that move about when they are wound up. Recalling or imagining such things, while their eyes are closed, helps to relieve the mind of school studies, which sometimes cause strain. Adults, especially mothers, listen to me while I am describing such things to the children in the clinic. When it comes time to treat the older patients, I find it quite easy to have them remember how surprised their children were on Christmas morning, when the tree and toys were discovered.

It was necessary to find out the ages of the children so that we could purchase suitable and useful gifts for them. There were sewing baskets for the older girls, and handkerchiefs, three in a box, for mothers and fathers. For the little girls, we had the dearest dollies, which we purchased at a reasonable price. Little boys received games and toys of all sorts, and enough money was given to a mother to buy a pair of baby shoes for her youngest.

One mother, who came quite regularly for several months before Christmas, was made very happy the day of our festival. She was invited to bring all of her children. There were seven and not one boy among them.

Dear old Pop from the Blind Men's Home of Brooklyn, was too feeble to be with us, but we remembered him just the same. Good smoking tobacco and some wearing apparel were sent to him and he was overjoyed.

While we were distributing the gifts, I suddenly remembered about the little rich boy who enjoyed a poor boy's gift the year before. There were a few toys left, and no more boys to receive them. The last little girl had received her doll and departed. There was one doll left behind. She was perched among the lower branches and looked rather lonesome. There was no one to claim her. I was rearranging the lights on the tree while all was quiet. When I turned away from the tree, I saw a little rich girl from the West, admiring the lonesome dollie. Dr. Bates also appeared on the scene, and when he nodded his head toward the little girl and then the doll, I understood what he meant. Both arms of the little girl reached out for a poor girl's gift. She held that dollie as though it were the only one in the world. I have learned so much about private and clinic patients, and I am glad to find that all boys and girls feel the same whether they are rich or poor.

Many thanks to my friends who make our clinic family happy at Christmas time.

#### THE CHRISTMAS FAIRIES

By George M. Guild

The night before Christmas is the time when most little children are happy, wondering how many of the toys they have hoped for will be found under the Christmas tree on Christmas morning. If it were not for the good fairies, Santa Claus would not know what each little child most desires. The fairies are always with the children, although they are not always seen. They know what the children are thinking, and what they are wishing for. The fairies are eager to help Santa Claus whenever he needs them, particularly on Christmas Eve when he is so busy.

In the country, where the snow does not melt quickly, Santa still travels in his sleigh driven by the reindeers. The jingle bells seem to say, "Good Cheer! Good Cheer!" and arouse merry thoughts in the hearts of all. It is different in the cities, where the snow is taken away as soon as it falls. Santa Claus has to use either his automobile or his aeroplane. (Unless he is able to land his sleigh on the roof and go down a chimney.)

In a crowded part of the city, where many poor people lived, the boys and girls were sad and lonely at Christmas time. One little girl, whose name was Mary, had no mother nor father, no sisters nor brothers. She had a great deal of trouble with her eyes and could scarcely see. While the other children in the neighborhood were looking in at the shop windows, wishing for the wonderful toys, little Mary went to sleep on her cot, hopeful that Santa Claus would not forget her. While she slept, the fairies and Santa Claus were very busy. The Queen of the Fairies gathered all the other fairies together. Some were sent to the woods for the largest Christmas tree that they could find. Others were sent to Toyland to bring back stacks and stacks of toys so that all the children could receive what they desired. All night long the Christmas fairies went back and forth from Toyland to the playground, where the large tree was placed for all to see it. They decorated the tree with strings of popcorn, long golden and silver ropes, and beautiful ornaments. The toys were arranged on all the branches and beneath the tree, too. The Fairy Queen touched the Christmas tree with her wand and many colored lights blazed forth. Just then Santa Claus arrived in his aeroplane and was very pleased with the work of the fairies. Soon after that the fairies climbed in the aeroplane with Santa Claus and sailed off to take care of other children.

When daylight came, the children looked out of their windows to see if the snow had fallen in the night. There in the center of the playground stood the beautiful tree. They ran outdoors, calling to their playmates as they went along. Soon an enormous crowd was gathered about the Christmas tree. They were all very excited and made a mad scramble for the toys, and they soon carried off all the presents they wanted. It took Mary longer than the others to reach the tree, because she could not see so well and had to walk slowly and carefully. Then, too, the crowd of children was so large and their eagerness so great that they did not think of little Mary, and she was pushed here and there. Finally, when the children had gone, Mary approached the tree, but she could not see any toys. She sat down and was about to cry when she heard the tinkling of bells and suddenly caught a glimpse of shining lights. She came very close to the tree, and there was one lone toy left among the branches. Mary reached for it and grasped it in her hands. She tried hard to see what it was, but all that she could see were two blinking lights, and each time they blinked they became a more beautiful color. As she continued to look at them, unknowingly she began to blink, too, and all at once she saw a little red and gold jester with cap and bells, and the ugliest face that she had ever seen. That was why all the other children had left it there. But she soon forgot his ugly face when she looked at his eyes again. As they blinked they changed from gold to blue, from blue to yellow, and from yellow to green, and again to a bright scarlet. They danced and twinkled all the while. Then the jester himself began to sway from side to side. This made Mary feel like swaying, and she began to move in time with the movements of the jester. All the while the bells on his cap jingled sprightly tunes for them, making Mary very jolly and gay. Then the jester began to hop up and down, and dance all about, turning 'round and round'. Mary began to dance, too. They danced here and they danced there, and they danced everywhere. They were circling around the tree when suddenly Mary stood still, surprised. She could see! Everything had become very bright. The jester nodded wisely. He knew it had not happened just then; it had been going on ever since she blinked and swayed and danced with him, but Mary had been too happy to realize the wonderful thing that had happened to her. She looked all about,—the whole playground seemed to sparkle. The Christmas tree had become very green, and she could see even the little needles on the boughs. Mary could not understand all this. The jester chuckled to himself. He knew it was the most natural thing in the world. Fairies just live to help people, and they think nothing of the things that everyone call miracles.

"Why! I believe it is you who have helped me," Mary suddenly said to the jester. "I do believe you are a fairy!"

The jester nodded, bowed, twirled around gaily and then blinked at Mary.

"I know," exclaimed Mary, "it is the wonderful things you do with your eyes that have helped me."

The jester nodded twice this time and bowed low. Mary hugged him tightly and ran to tell the other children about the Fairy Jester. What she did not know was that he was the Prince of the Jesters in disguise and went about curing people just as he had cured Mary.

## AN OPTOMETRIST'S EXPERIENCE

By Dr Paul Hotson

Editor's Note - Dr. Hotson is among the first optometrists to practice the cure of imperfect sight without glasses. This does not mean that he has given up prescribing glasses, but it means that he can now offer his customers a choice of treatment with or without glasses.

For many years people have been taught to believe that there is no relief from eye troubles, except through glasses, and it is hard to make them believe anything else.

Sixteen years ago, I started practicing Optometry, and still hold a license. Fourteen years of that time I swallowed and digested the old theory of refraction, although it is full of contradictions which could be demonstrated to the average optometrist in a few minutes.

According to the old theory, near-sight is incurable, but when you improve the vision of a near-sighted child until it can read two or three lines down on the test card, or even obtain normal vision in one treatment, the old theory falls to pieces. These facts have never been brought to the attention of optometrists in general.

Eyestrain can be cured so easily in the average child by Dr. Bates' method that it should be against the law to fit children with glasses. I predict that within twenty-five years there will not be a child wearing glasses in either the United States or Canada.

## A CASE OF CHRONIC HEADACHE

Girl, 16 years old, Right eye 10/10, Left eye 10/10 (with one mistake). Had **headache constantly for over a year**, medicine did not relieve, and at times she was not able to sleep at night on account of the pain. **Right eye had turned slightly in and patient saw double.** Headache was completely relieved during first treatment by palming and the memory of a dahlia, which was her favorite flower. She came to my office twice a week and was cured in ten days. The treatment consisted of **palming, swinging, blinking and the memory of a small letter o.** Her vision Improved to 22/10 and both eyes became straight.

### CURED IN ONE TREATMENT

Child ten years old. Vision 10/30. After palming ten minutes, swinging improved the vision to 10/10 in each eye during the first treatment.

### FAR-SIGHT AND ASTIGMATISM

Girl thirteen years old. Had worn strong specially ground lenses for three years on account of **headache**. She was instructed to palm fifteen minutes, five times a day, swing small letters on the test card and read her school books by looking at the spaces between the lines. When she came for the third treatment, which was seven days after I first saw her, the headache had disappeared. She is now able to study as long as she likes without the least inconvenience.

(When reading the print; the eyes look directly at the print. Looking at the white spaces is done before reading the print.)

### GLASSES HELPED THIS BOY

Boy 14 years old. Without glasses he read 12/10 with only three mistakes, and at ten feet he could read all of them with each eye separately. In two weeks his vision improved to 15/10. Headaches disappeared and he had no more trouble with his eyes. Palming fifteen minutes four times a day, and swinging the small letters cured him.

He had worn near-sighted lenses for four years to relieve headaches. While this boy was not near-sighted, he contrived to enjoy great comfort from the lenses. So much so that when he forgot them, he would go back a mile in order to have the glasses for his school work.

### AN OCULIST'S EXPERIENCE

By E. F. Darling, M.D.

Editor's Note - This contribution from an **oculist of twenty years' experience in one of the largest Eye Hospitals in the United States** is of unusual interest. He is to be congratulated on his perseverance in going without glasses so long before his sight for reading had sufficiently improved to do his work properly. He has not told of the opposition and loss of many of his old friends because he did not prescribe glasses for his patients.

I have been practicing medicine as an ophthalmologist for the last twenty years. During a period of eighteen years prior to 1923, I spent a large part of my time putting glasses on my helpless patients.

However, for the last two years I have been trying to make amends by removing their glasses as rapidly as possible.

The first time I heard of Dr. Bates' work was from an article in one of the medical journals about fifteen years ago. The article made some impression on me, because it was entirely at variance with our accepted views as to the cause and cure of defective vision. In the clinic I attended, at one of the largest eye hospitals, most of the men seemed to know nothing about Dr. Bates. Some thought he was a quack, while others said he was insane.

About three years ago I received notice of the publication of his book, "Perfect Sight Without Glasses," and at that time I decided to purchase the book and see what it was all about. The thing slipped my mind for another year or so, when one of my old patients came into my office without her glasses on and said she had been working with Dr. Bates. Her vision was much improved, and she wanted to know if I could continue the same kind of treatment with her. I was obliged to confess that I knew nothing about his methods, but I believe I at least volunteered the information that he ought to be in jail.

The next day I went over to the Central Fixation Publishing Company and bought the book. When I reached home, I started reading it and didn't stop until I had finished the whole thing. Here was a plain statement of facts accomplished, and I at once decided to test the matter with my own eyes.

I was wearing convex 2.25 D. S. for distance and convex 4.25 for reading. My distance vision had deteriorated in the eighteen years I had worn glasses, from better than normal to about one-third normal. My near vision had gone back so much that I was wearing the glass which theoretically should suit a person sixty or seventy years old. With the glasses off I could see only the largest headlines on the newspapers. While wearing the glasses, I had occasional headaches and eye aches, and my near vision was at times very defective, so that I had difficulty in doing fine work of any kind.

The first day I went around without glasses everything seemed blurred, but I felt somehow that I had gotten rid of some particularly galling chains. It was pleasant to feel the air blowing against my eyes, and I walked around the whole afternoon trying to get used to the new condition.

In carrying out the suggestions in Dr. Bates' book, I had a great deal of trouble for the first week or so, especially with the mental images. This was simply due to my extreme eyestrain. In spite of this my vision steadily improved by palming, so that at the end of three weeks I could read the 10/15 line instead of the 20/70 line. I had only an occasional eye ache when I had forgotten to use my eyes properly.

In improving my near vision, I had to make several visits to Dr. Bates, and he overcame most of my difficulties at once. I used many of the methods he advocates in this near work, but it was about three months before I could read fine print. It seemed an extremely long, long time to give up reading, but knowing now the advantages after an experience of two years without glasses I would be willing to go without reading for a much longer period. Many people of the same age get results in a much shorter time than I did. I feel more and more strongly that a person will not have full control of his mental faculties until he gets rid of his glasses. Whether it takes two weeks or two years, the result will pay for the deprivation.

At present I usually read an hour or so in the daytime and three or four hours at night with no eyestrain whatever. Previously I used to walk along with my eyes fixed on the pavement because of the discomfort in taking note of passing people or objects; now it is a great pleasure to examine things minutely. In my work I can go nine hours with about the same fatigue as I felt before in three or four hours. In other words, Dr. Bates' work has changed me from an old man of forty-eight to a young man of fifty. I now enjoy the practice of medicine for the first time since finishing my hospital internship, as I am absolutely certain that if patients will carry out my directions their whole condition will be improved.

In no case can the time required to obtain normal vision be definitely stated. People of the same age and wearing the same strength glasses vary in time required as much as they differ in color of their hair or size of their appetites. Some get quick results, others drag along indefinitely before they get where they should be.

These slow cases require lots of encouragement, and it sometimes takes all their own and the doctor's perseverance to keep them going.

## SOME INTERESTING CASES

By Mildred Shepard

Editor's Note - Ms. Shepard has done much good work in the cure of imperfect sight by treatment without glasses. She came to me as a patient about five years ago and was treated for hypermetropia or far-sightedness accompanied by astigmatism. She had suffered with pain and fatigue whenever she used her eyes. After her sight became normal, Miss Shepard began to treat her friends. She became so interested in curing them of imperfect sight that she decided to take my course.

Ten days ago a lady came to me after having **worn glasses for twenty years**. She is now forty-five. Her vision with both eyes was 14/70, and with the left eye she read two letters of 14/50.

Her mental pictures were good, and after palming a while she became able by the use of her memory to read 14/20.

When she came for her second lesson, she could read 14/50 easily, and improved to 10/15. She understands the general principles and wants to work by herself for a couple of weeks. I hope that she will have 14/10 when she comes again.

Another near-sighted young lady of twenty-four, a school teacher, read 14/40 and some letters of 14/30 the first day of her treatment. The same day she improved to 14/20. One week later she read 14/15.

Two of my pupils have gone back to their oculists for examinations, the results of which were rather interesting. In one case the man wanted to get a pair of glasses, which he could use when he sat in the top balcony of the Opera House. When the oculist examined his eyes and compared it with the previous examination, he found so much improvement that he refused to prescribe glasses for him. His vision had improved from 10/30 minus with the right eye and 10/40 with the left to 12.5/10 with both.

In the other case the examination showed  $1\frac{1}{2}$  diopters of myopia instead of  $3\frac{3}{4}$  which had been present before. **This man had a pair of still weaker glasses made up**, to wear while working under trying and unusual conditions. He hopes soon to discard the glasses altogether. His vision improved from 20/70 to 10/10.

Last spring a young girl of twenty-two came to me. She had worn glasses for nine years. Her vision was 20/200 with both eyes. With the right eye it was not so good. She had six lessons in ten days and became able to read 10/10 on the black card. Six months later she returned. Her vision was still 10/10. She was so enthusiastic that she brought her mother and a friend, both of whom had lessons. She wants to go into the work after she improves her sight still more.

Another girl of fourteen whose vision was 7.5/100 last February can now read 8/10 on the black card, and when she once masters central fixation I know she will get back to normal vision.

Another has improved from 6/200 to 5/30. She still has a long way to go, but she is faithful, and we both are hopeful.

I might go on indefinitely giving other cases, some similar and some quite different.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JANUARY, 1926

### The Period

**THE perfect memory or imagination of a period is a cure for imperfect sight.** Only the color needs to be remembered. The size is immaterial, but a small period is remembered with more relaxation than a large one. It is true, however, that with perfect sight, one has the ability to remember all things perfectly.

One cannot remember a period perfectly by any kind of an effort. It usually happens that one may remember a period for a time, and then lose it by an effort. To remember a period stationary, is impossible. One has to shift more or less frequently in order to remember one period perfectly all the time, or one has to imagine the period to be moving, or one has to remember the period by central fixation,—one part best. By shifting, is meant to look away from the period and then back, but to do it so quickly that it is possible to remember the period continuously, although you are not looking at it all the time,—this with the eyes closed. Every time you blink, you shift your eyes. You can blink so rapidly that it is not noticeable. When you close your eyes and remember a period, you cannot remember it unless you are, with your eyes closed, going through the process as though you were blinking, looking away from it and back again, but so quickly that it seems as though you were looking at the period continuously. You cannot remember the whole of the period at once. No matter how small the period is, you cannot see or remember it perfectly, all parts equally well at the same time. You cannot remember the period perfectly by any kind of an effort. When the memory of the period is perfect, the mental and physical efficiency is increased. A perfect memory of the period does not necessarily mean that one should think only of the period.

Shift on the period from part to part, small point to small point: left and right, top and bottom, diagonally and in any direction.

Imagine a period.  
Shift point to point on  
the period, shift away  
from it and back  
quickly, see it move  
as the eyes shift.  
Practice with the eyes  
open, closed, open.

## Swinging

By W. H. BATES, M.D.

*Swinging: When the eyes move slowly or rapidly from side to side, stationary objects appear to move in the direction opposite to the movement of the head and eyes.*

PEOPLE with normal vision are not always conscious of the swing. When called to their attention, however, they can always demonstrate it, and are always able to imagine all stationary objects to be moving. In imperfect sight, the swing is modified or absent. This is a truth which has been demonstrated over a long period of years by a great many people, and no exceptions have been found.

The normal or perfect swing is slow, short, easy and continuous. When the swing is normal, it is always true that not only is the vision normal or perfect, but also the memory, the imagination, or the mental efficiency correspond. When the memory is imperfect, the imagination, the mental efficiency, and the sight are also imperfect.

All cases of imperfect sight from myopia, or near-sightedness, become normal when the swing becomes normal. The same is true in cataract, glaucoma, diseases of the optic nerve and retina. For example, a woman, aged sixty-three, was treated for imperfect sight from cataract. Her vision was 10/200, and was not improved by glasses. For twenty years she had not been able to read a newspaper with or without glasses. In three visits, with the help of the normal swing, her vision improved to 10/10 minus, with flashes of normal vision, and she read diamond type at twelve inches rapidly without glasses. Other similar cases have been relieved as promptly.

It is important to understand how the swing can be imagined. Some people with mild cases of imperfect sight can imagine a letter or other object to be moving when they see or remember it perfectly. There are many others who fail. Severe pain, fatigue, or worry often prevent the demonstration of the swing. Blinking and palming are helpful in demonstrating the swing. The distance of the object regarded is important. The patient should be placed at a distance at which he can best demonstrate the swing. The distance varies with the patient.

It is unfortunate that many patients consider the swing complicated or impossible. However, they can usually demonstrate that a stare or strain lowers the vision. When holding a test card at a convenient distance from the eyes, patients may be convinced that the test card is seen better when moving. They may not profit by their experience, but continue to stare or strain, which always lowers the vision.

One patient was unable to imagine any kind of a swing. He was suffering from pain, mental depression, and imperfect sight for the distance. Reading the newspaper, even with glasses, was impossible. Since nothing he tried gave him any relief, I suggested that he stop trying to see and make no effort to imagine stationary objects to be moving. He practiced this while sitting in my waiting room. He paid no attention to the apparent movement of stationary objects, nor did he look at any object more than a fraction of a second. His vision after that improved from 20/50 to 20/10. He became able to imagine the movement of objects and demonstrated that all his pain and mental depression were caused by a stare or an effort to see all things stationary, when he regarded, remembered or imagined them. He was comfortable when he imagined objects moving or swinging, but very uncomfortable when he made an effort or imagined them to be stationary.

Recently, I tested the sight of a girl about ten years old. She read the Snellen card at ten feet with normal vision. She was asked: "Do you see any of the small letters moving from side to side?"

"Yes," she answered, "they are all moving."

"Now can you imagine one of the small letters stationary?" At once she quickly looked away and frowned.

"Why did you look away?" her father asked her.

She replied: "Because it gave me a pain in my eyes and head, and the letters became blurred. Don't ask me to do it again."

The experience of this child is the same as that of everyone, young or old, with perfect or imperfect sight. When the sight is normal and continuously good, to try to stop the swing of a letter or other object necessitates a strain,—an effort which always lowers the vision and produces discomfort or pain in one or both eyes.

It has been repeatedly demonstrated that a letter or other object cannot be remembered or even imagined perfectly and continuously, unless one can imagine it to be moving or swinging. Not only does the sight become imperfect, but also the memory, imagination, judgment, and other mental processes are temporarily lost. These facts should be known to teachers, because they greatly affect the sight, the mental efficiency, and the scholarship of their pupils.

**When the memory, imagination and vision are normal, the eyes, the brain and the entire nervous system are at rest.** The reverse is also true, for when the muscles and nerves of the body are not at rest, the sight, memory and imagination are imperfect, and the mental efficiency is lessened or lost.

It is impossible to imagine pain, or any symptom of disease and the normal swing at the same time. Children with whooping cough have been immediately relieved by the relaxation obtained from the swing. Many patients suffering from severe attacks of bronchitis have been promptly relieved in the same way. Angina pectoris, pneumonia, trifacial neuralgia, and other serious diseases have also been relieved after relaxation or rest was obtained with the aid of the swing.

The swing is generally beneficial. Some patients obtain more relaxation from one type of swing than from another. The long swing, however, is most helpful in a great many cases.

**LONG SWING:** Stand with the feet about one foot apart. Turn the body to the right, at the same time lifting the heel of the left foot. The head and eyes move with the movement of the body. Do not pay any attention to the apparent movement of stationary objects. Now place the left heel on the floor, turn the body to the left, raising the heel of the right foot. Alternate. Pain and fatigue are

# E

Shift left and right on the E and see it move in the opposite direction the eyes move to. Shift top and bottom, diagonally and in any direction.

The Long Swing

Swing and turn left and right.  
Swing, turn left—the heel of the right foot moves up.  
Swing and turn right—the heel of left foot moves up. 50-100 times.

Long Swing relaxes the mind, body, eyes, activates eye shifting, clear vision. Do the Rock (sway) a shorter swing for increased vision improvement. See oppositional movement.

**The Long Swing with Two Eyecharts**  
Identical eyecharts placed on left and right side of the body. Swing and turn left and right and "Flash" glance at, shift on a letter on the eyechart for a "fraction of a second".  
Swing, turn left and "flash" a letter on the left chart: Blink and shift quickly, easy on the letter. Do not stop swinging.  
Swing and turn right and flash a letter on the right chart. Keep swinging left and right, glancing at the letters. Relax, no effort to see—vision becomes clear.

relieved promptly while practicing this swing. When done correctly, relief is felt in a short time. The long swing, when done before retiring, lessens eyestrain during sleep.

**VARIABLE SWING:** Hold the forefinger of one hand six inches from the right eye and about the same distance to the right. Look straight ahead and move the head a short distance from side to side. The finger appears to move in the direction opposite to the movement of the head and eyes.

**DRIFTING SWING:** The patient does not think of nor regard anything longer than a fraction of a second. It is helpful in doing this for the patient to imagine himself floating down a river. He may be able to imagine the drifting movement of the boat in which he is floating, better with the eyes closed than with them open. In this case, alternate the imagination with the eyes open and with them closed. The imagination may be improved in this way.

**SHORT SWING:** When the sight is normal, one can demonstrate the short swing. When it is imperfect, one can demonstrate only the longer swing. When a patient with imperfect sight regards the Snellen test card at ten or fifteen feet, he may be able to imagine one of the letters on the card to be swinging a quarter of an inch or less. The imagination of a shorter swing always improves the sight. Some patients can imagine the short swing better with their eyes closed than with them open. Alternate the imagination of the swing of the letter with the eyes closed and with them open. By repetition, the vision of the letter with the eyes open will improve (at first in flashes, later more continuously), if the memory of the short swing is perfect with the eyes closed.

**UNIVERSAL SWING:** When the eyes are at rest, they are always moving. When the body is at rest, it can always be imagined, one part in turn, to be moving or swinging. The chair, on which the patient is sitting, is swinging. The floor, on which the chair rests, is also swinging. The walls of the room also swing when the floor swings. When one part of the building swings, one can imagine the whole building to be swinging. The ground, on which the building stands, is also swinging. When the ground swings, other buildings connected with it swing. One can imagine the whole city to be swinging, this continent and all other continents on the earth can be imagined swinging. In short, one can imagine not only that the whole world is moving, but also the universe, including the sun, the moon and stars. The practice of the universal swing is of the greatest benefit, for in this way one can obtain the maximum amount of relaxation.

All objects appear to move, 'swing' in the opposite direction the eyes shift to.

The Figure Eight shown below is a new, improved version of a few different swings combined into one.

Trace up the center and to the left first for correct left and right brain hemisphere activation, integration.

Variable Swing with finger to side of face. Move the head left and right and see the finger move opposite.

Variable Swing with finger in front, center of face, between the eyes, eye level.

Long Swing

Swing the body left and right. Head/face, eyes, body move together, at the same time, in the same direction. See oppositional movement; objects in the visual field appear to move 'swing' by in the opposite direction. Do not stop to look at the objects. Keep swinging, relax and let them move.

Variable Swing with the finger in front of the face. Move the head left and right and see the finger move in the opposite direction.

Drifting Swing. Let the mind, eyes drift, shift freely from one thought, object to another. Relax.

Shift left and right, top and bottom on a small letter and see it move 'swing' in the opposite direction. Practice with the eyes open, closed, open.

## Stories from the Clinic

### No. 71: PARTIAL PARALYSIS OF THE THIRD NERVE

By EMILY C. LIERMAN

GEORGE, aged five years, was sent to me by a physician, who diagnosed his case as paralysis of the third nerve of the right eye. A number of eye specialists said that he could not be cured. One gave him internal treatment for about six months and used electricity on the eye without much permanent benefit. When a nerve is paralyzed, its function is lost. In other words, the nerve is not able to bring about a contraction of the parts supplied by the nerve. To explain further, that branch of the third nerve distributed to the muscle which raises the lid had lost its function. In general, it has been believed for many years that a paralyzed nerve is relaxed. After many years of observation and experimental work, it was demonstrated that a paralyzed nerve was under a great tension. Treatment which relieved the tension and brought about a sufficient relaxation was a cure for the paralysis.

In Dr. Bates' book is an illustration of a patient with paralysis of the seventh nerve. One of the functions of the seventh nerve is to close the eyelid. When it is paralyzed, the eye remains open. Not only does the eye remain in this way, but the lips are separated. The patient is not able to close the lips sufficiently to whistle. By palming and swinging, relaxation is obtained,—the patient becomes able at once to close the eyelid, and to close the lips sufficiently to whistle. These cases of paralysis do not need electrical nor other stimulation. They are cured by rest. I believe that electricity is a valuable remedy, but it has lost much of its prestige by being employed in cases where it was not needed.

Georgie's mother has unusual intelligence, and she came to us confident we could relieve or cure Georgie's eyes. This is the history of his case as she described it: When he was born his right eye was wide open, and the child was unable to close the eye. About three months later the eyelid closed, and the child was unable to open his eye. Several eye specialists in Brooklyn told the mother that the eye could not be cured.

From the very beginning, Georgie was a source of pleasure to me. He seldom spoke above a whisper and preferred to go through each treatment without speaking at all, if possible. At such times he was given the card with the letter E pointing in different directions. When I asked him which way the E's were pointing, as I pointed to each one with my pencil he would say left, right, up, down. But if he were not in the mood, he would raise his hand and indicate the direction in which the E was pointing. In the beginning, this card was the only one used in his treatment, because he did not know all the letters of the alphabet. After he was admitted to the kindergarten school, he asked for the alphabet card, and also a figure card, which children favor a great deal for testing their sight. When Georgie's first test was made, he was unable to open his right eye. The left eye was normal, or 10/10.

I taught him to palm, and while he sat quietly, I began to talk to his mother. The conversation was solely for his benefit, so I talked about him. Like all mothers of her type, she praised her little boy and informed me of all the wonderful qualities of his mind, and that he was most obedient. I saw him smile, and for a moment he peeped a little through his fingers. After he had rested his eyes for ten minutes, I told him to keep his left eye covered, and look at the card with his right eye. His mother sat facing him, with her eyes wide open with astonishment, as she saw the eyelid open just a trifle. He was able to keep his right eye open long enough to read 10/70, then the eyelid dropped again. His mother obtained a number of different Snellen test cards and used them at home for the daily treatment of the paralyzed eye.

I treated Georgie again, one week later, and I immediately had him practice the palming. So many patients have failed to palm successfully, because they stare even with their eyes closed. Georgie palmed successfully because, at my suggestion, he remembered the things that were pleasant and easy to recall. If I could not think quickly enough of a story to tell him, I would show him something in my room which pleased him. Then he would palm and describe it to me. At one time I showed him a box of bonbons, which were attractively arranged, and promised him some if he would sit and palm for a long time. His mother and I were amused, because he was unusually quiet when he remembered the candy. After he had palmed awhile, I suddenly asked him what he was thinking about. He opened his eyes long enough to say the word "candy" and then closed them again. The vision of his right eye improved from 10/70 to 10/50 that day, and the eyelid was more open than before. The left eye improved to 12/10.

At every visit his vision was improved, while the paralysis diminished with the increased relaxation of his eye. I noticed that occasionally he would forget to blink, and then he would stare and strain, which lowered his vision and increased the paralysis. His eyelid has opened more, and his vision has improved since he became the owner of a little puppy. Whenever he played with the little dog, his mother noticed that both eyes would blink. This is evidence that things seen in motion are seen best. The vision of his right eye was improved to more than 10/10, while that of his left eye to 18/10, which is very unusual in a child six years of age. He had been under my treatment for about a year.

## The Blinking Knight

By GEORGE M. GUILD

INSIDE a dark, dingy, little shop, a group of children bent over their work. Outside, New Year's revelry echoed along the streets, but the day held no joy nor merriment for these little workers. It was just like every other day. It meant sitting from early morning until late at night stringing countless numbers of little beads together, to make ornaments. They stooped over their tasks until their sight grew dim, and colored spots danced before their eyes. They could not stop their work nor rest for even a moment, but the angry proprietor prodded them on.

Today, fear and dread settled in the hearts of the poor children. Had they not been told that their work was very bad and that they would be dismissed? They knew it was, because they could not see to match the beads in the dull light of the shop. Perhaps glasses would help them, but where was the money to come from?

As evening approached, the light grew dimmer and dimmer. It seemed to the children that they could no longer go on, when from a dusty corner they heard a voice say, "Good evening, children." As they looked, they saw a light shining. The light grew stronger and stronger, and seemed to fill the room. The little workers almost shouted aloud with joy. Suddenly a little man with a flaming sword jumped out to the center of the room. On his head he wore a soft velvet hat with a very large brim; a cluster of huge diamonds shone on the front, while smaller ones covered the hat band. His coat had a long tail, which swayed with every movement he made. The many glittering

The Blinking Knight

buttons were immense diamonds. His yellow vest, which contained a great many more pockets than any vest the children had ever seen, was decorated with diamonds, rubies, emeralds, and sapphires. His violet trousers reached only to his knees, and they, too, were covered with jewels. He wore long stockings of fiery red, and his low patent leather shoes were trimmed with large silver buckles. The belt of the scabbard for his sword sparkled with jewels.

When the children gazed on this knight, they became very quiet and curious to know who he was. His eyes were sympathetic as he smiled good-naturedly on them. When he spoke, his voice was like music to their ears and made them all feel comfortable and at peace with the world. "Children," he said, "the fairies have sent me to help you to be happy. I love each and every one of you and want to cure your eyes, so that you will be able to have perfect sight all the time. You will be able to see even in the dimmest light without glasses. All of you are working too hard. Make believe that you can see fairies, that you can talk with them, dance with them, and be like them. When I was a boy, I wanted to be a fairy, but when I grew up, the king made me a knight and sent me out into the world to slay as many bad people as I could. I was very skillful at doing this.

"One day, while riding through a wood, I saw some blue flowers. They were so beautiful and fragrant that I said aloud, 'Oh, you lovely blue flowers, how I wish you were all fairies,' and then, much to my surprise, every flower turned into a blue fairy. They climbed upon my steed and urged him to canter as fast as he could. Very soon we came to a field of beautiful yellow flowers. While I looked at them, entranced, myriads of little yellow fairies danced gaily from the petals and mingled and danced together, leading us on, until we reached a meadow of violets nodding in the breeze. They were even more beautiful than the others. I wished that they too were fairies. All at once the violets turned to violet fairies and they frolicked with the other fairies."

The knight ceased to speak for a moment and then suddenly held up a bouquet of blue, yellow and violet flowers. The children saw him leap to the middle of a large table in center of the room. There he began to dance, and as he danced he blinked his eyes and waved the flowers around his head, crying out to the children, "Make believe that these flowers are fairies. Remember the colors perfectly. Blink your eyes as you see me blinking, and never forget what you will see now." Immediately the flowers all turned to fairies of the same color.

At once they all began to dance around the blinking knight, laughing, shouting, and enjoying themselves. The knight touched each child in the shop with his wonderful sword, and each child as soon as she was touched, turned into a fairy. Some blue, some yellow, and some violet, and all blinking as frequently as the blinking knight.

"Now that you are all fairies," he said, "you must think, remember, imagine, and believe all things which are good. Tomorrow morning, you will all waken and believe that all this was a dream. I want to tell you that I was born a thousand years ago. I speak with the wisdom of the ages when I say to you, that if you will only remember me and make believe that you are fairies, you will always be happy and good the rest of your lives."

## How Estelle Helped

By BEATRICE SMITH

THERE are many cases of imperfect sight, many cases of pain and fatigue, which can be cured by other patients who have obtained normal sight without glasses by practicing relaxation methods.

About three years ago, a young man, aged seventeen, suffered very much from pain in his right eye. The pain increased quite rapidly and finally became so severe that in order to get any relief, he was compelled to take morphine. As time passed, the dose of morphine was increased and increased with unusual rapidity. The outlook seemed dismal. The eye specialists in some of the large cities prescribed glasses for him, but without benefit. One day while walking along the street, he met a lady whose daughter had been cured by the treatment of imperfect sight without glasses, discovered and practiced by a physician living in New York City. The lady recommended him to practice palming, swinging and some other methods described in a book called *Perfect Sight Without Glasses*. The palming gave instant relief. By palming for fifteen minutes every night and morning, the pain was relieved or prevented. This treatment was continued for some months, usually about three times daily for fifteen minutes each time. As the days went by without a return of the agonizing pain, he practiced palming less frequently, until after three months, not having had an attack of the pain, he stopped the palming and forgot all about his right eye.

The patient lived in one of the large cities of the West. It was interesting to learn of the great number of people who followed the treatment of this case of pain and kept in mind all the particulars. When the boy began to lessen the number of treatments by palming, some of his friends were very much concerned for fear that he was stopping the treatment too soon. When he remained free from pain for some time, they were relieved, but still more or less apprehensive. I believe the boy felt deep down in his heart that if that pain ever came back, he would know how to handle it.

The patient, who recommended the boy to palm, had a daughter about ten years old, who had been to New York, taken the treatment and been cured of imperfect sight without glasses. This little girl kept after the young man in the early days of his treatment and insisted that he practice all those methods, which were beneficial, repeatedly and continuously. I believe it was the efforts of the little girl, which did more than anything else to benefit the patient. True, he was willing to palm and did palm, but there were days when he would forget and she kept after him until he was cured.

I believe that she had more to do with the cure of the boy's pain than did the supervision of other people.

## A Student's Experience

By MARGARET ROBINSON

**AUTHOR'S NOTE**—Dr. Bates has asked me to send some report in regard to my teaching of his methods in Bloomington, Illinois. Converts to the truth of Dr. Bates' explanation of eye troubles are persuaded that glasses, for the average person, are unnecessary, also, that the vision is lowered as a result of their use. It is appalling to find how many people are actually struggling with glasses, which, they have been told, would relieve their strain and save their vision. If, in my very limited experience, I have found so many of this type, there must be a great number of such unfortunates in every community. The three following cases illustrate what I mean:

**MISS I.**, age thirty, had worn glasses since she was ten years old. In the past two years, since a goiter operation, she said she had visited the oculist at least once a week. He had changed her glasses four or five times during this period, had stopped all reading, and was putting medication in her eyes to relieve a distress, which she said was almost constant. He seemed uncertain what to do next, as her vision was steadily growing worse. With her glasses she read 10/30 with both eyes and 10/200 with the right eye alone. After taking off her glasses and palming for a short time she read better than 10/20 with both eyes, and almost 10/70 with the right eye. The near vision of the right eye was also impaired. On the first day, she could not read ordinary type with this eye alone. In two weeks she lost all sense of strain and read 10/10 with both eyes and began to read 10/50 with the right eye. She read diamond type readily with both eyes together and slowly with the right eye alone, at six inches. She reported that she was able, without fatigue, to read two hours or more at a time, day or evening. She looked and acted ten years younger.

**Miss J.**, age forty-two, was very much frightened about her eyes, and very loath to give up the large glasses behind which her eyes looked so tired and drawn. She had been forced to give up her position at an embroidery counter because of the failure of her vision. In eight months she had had three different pairs of glasses, and said that the oculist told her frankly that he was much puzzled as to how to relieve her very serious strain. Four lessons, with her intelligent co-operation, and less than a month's time, relieved the situation. Her eyes were comfortable and she was able to see satisfactorily for reading and sewing, as well as at a distance. The look of relief on her face was very gratifying.

**Mrs. W.**, age forty-nine, had suffered with very severe eye difficulties for twenty years. She had been forced to give up her piano work, could do practically no reading, and said, in fact, that many of the interests of her life had been dropped because of her eyes. Bright lights, and use of her eyes for close work, produced a sharp pain in her head which she had learned to greatly dread. Said for about a year she was allowed to use "very strong" glasses ten minutes at a time. Of late she had used them longer than that, but it made her eyes very tired to do so. There were dark rings under her eyes and she was very nervous. Without her glasses she was able to read 10/15, also large clear type at reading distance but better at arm's length. She did this, however, with fear and trembling, often stopping to close her eyes. In two weeks, she was reading 10/10 readily without fear, also getting flashes of clear vision when practicing with the diamond type card held at six or eight inches from eyes. She was comfortable, had lost all dread of bright lights, did not get the pain in her head any more, and was losing the dark rings under her eyes. She stopped taking lessons at this point, but continued to improve, according to reports which reached me several months later.

In each of these cases, glasses were not only useless, but actual torture. In each case the individual had given up what she wanted to do because of her eyes. In each case a couple of weeks without glasses, combined with learning how to relieve the eye strain, made life, as each wanted to live it, possible. It seems incredible that the 'value of such facts is not more quickly and more generally accepted.

## Questions and Answers

**Q**—I can read with no trouble but cannot distinguish things at a distance, especially the features of people. What would you suggest?

**A**—You are near-sighted. The imagination cure is the quickest and most satisfactory cure of myopia. Use two Snellen test cards, one held at one foot or nearer, or at a distance where you can see it best; the other placed at five feet or further. Look at the first letter of one of the lines of the near card and with the eyes closed remember it for half a minute or longer. Then look at the same letter on the distant card at five feet or further and imagine that letter for not longer than a second. Then look at the near letter again for part of a minute, close your eyes and remember it, and then glance at the same letter on the distant card for not longer than a second, and imagine it as well as you can. Alternate. When you become able to see the bottom line on the distant card, place it a few inches further off and repeat.

Practice with both eyes together, one eye at a time, then both together again.

**Q**—What method is most helpful in myopia?

**A**—Palming, swinging, and the use of the memory or imagination (described above), are most helpful.

**Q**—Can you tell me what to do for inflammation of the white of the eye? Do you think sun gazing would help?

**A**—The light treatment is beneficial. Sit in the sun with the eyes closed and let the sun shine directly upon the closed eyelids. Move the head a short distance from side to side. Practice this for half an hour or longer three times daily when possible.

**Q**—Will you kindly tell me what I can do in order to read as well with the eyelids fully open as I can when they are slightly parted?

**FAR**

**CLOSE**

Imagination cure for near-sightedness.

Two identical Eye charts placed at close (clear) and far (unclear) distances.

+ Eyes open - Shift on a letter on the close clear chart.

+ Eyes closed - Remember, imagine the letter clear, shift on it in the mind 30 seconds or longer. (10-15 seconds is ok.)

+ Eyes open - look at, shift on the same letter on the unclear distant chart, for a second or less, and remember, imagine it clear.

+ Look at the letter on the clear close chart again 10-15-30 seconds or longer, then close the eyes and remember it.

+ Then look at the letter on the distant card again, second or less and remember, imagine it clear.

+ Repeat.  
+ Practice on smaller letters and at farther distances.

**Sunning.**

Face the sun, eyes closed, move the head side to side.

**Saccadic Sunning.**

Sit under a tree with partial shade, sunlight shining through the branches, wind blowing the branches causing moving light and shadow to flicker on the closed eyes. Activates eye, eye muscle relaxation, tiny shifts, eye movements, very clear vision.

A—Improve your vision with the aid of the imagination cure as described above in answer to question 1. When your vision improves, your eyelids will be more open.

Q—Is there any exercise or any particular, method of relaxation that will help double vision?

A—Closing the eyes and resting them is a cure for double vision. Blinking frequently, just as the normal eye does, is also beneficial.

Q—Please explain the elliptical swing.

A—In the elliptical swing, the head and eyes are moved continuously in the orbit of an ellipse or a circle. The continuous movement of the head and eyes prevents the stare or strain, since staring requires that one try to keep the eyes from moving.

Elliptical swing

Figure Eight

The Figure Eight, Infinity Swing is a modern variation of the Elliptical Swing.

Q—How many times a day should the sun treatment be given?

A—The sun treatment should be given for half an hour or longer three times a day, or more often, when possible. The more sun treatment, the better, as it rests and strengthens the eyes.

Q—What treatment helps most people?

A—Palming is generally most helpful.

Q—Is it possible for some people to be cured by the help they may obtain from your book "Perfect Sight Without Glasses"?

A—Yes. By practicing the methods recommended in my book, many readers have improved their vision without my supervision. It helps to have someone with perfect sight supervise your treatment.

Q—Is myopia hereditary?

A—No. It is, however, contagious in many cases. When parents are cured of myopia, their children may recover without treatment.

Q—How long does it take to cure an average case of myopia?

A—Some patients are cured more quickly than others. The length of time is uncertain, as patients differ in their response to treatment.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

FEBRUARY, 1926

### Demonstrate

1. That an effort to see always lowers the vision. Look at the Snellen test card at a distance of twenty feet. It may be possible for you to see the large letters and read them without any apparent effort, while the smaller letters produce a strain which you can feel. If you consciously increase the effort to see the smaller letters, your vision becomes more imperfect. It is not easy for you to realize that effort is always present when the vision is lowered. Knowing the cause of your imperfect sight is a great help in selecting the remedy.

2. That a stare always lowers the vision. It is a truth that the normal eye blinks very frequently. In order to have normal sight, the eyes must blink. One can demonstrate that, when the patient looks at one letter at the distance with normal sight, or looks at one letter at a near point where it is seen clearly, keeping the eyes continuously open without blinking for a minute or longer, always lowers the vision for the distance or for the near point. This should convince the patient that blinking is absolutely necessary in order to obtain good vision.

3. That palming, when done correctly, improves the vision. When the closed eyes are covered with one or both hands, and all light is excluded, the patient should see nothing at all, or a perfect black. This is a rest to the eyes and always improves the sight at least temporarily. Palming can be done wrong. When it is practiced incorrectly, the field imagined by the patient contains streaks of red, white, blue, or other colors. The eyes are under a strain, and the vision is not materially improved by the wrong method of palming. It can be demonstrated that palming for half an hour or longer is a greater benefit than palming for only a few minutes.

## Memory

By W. H. BATES, M.D.

*When the sight is normal, the memory is perfect. The color and background of the letters or other objects seen, are remembered perfectly, instantaneously, and continuously.*

ONE of the quickest cures of imperfect sight has been gained through the use of the memory. When the memory is perfect, the eyes at once become normal with normal vision. A perfect memory changes the elongated eyeball of myopia into the shorter length of the normal eye. No matter how high a degree of myopia one may have, when he has a perfect memory of some one thing, he is no longer myopic, but has normal eyes with normal vision.

An imperfect memory or an imperfect imagination may produce organic changes in the eyeball. The organic changes, which are present in many diseases of the eye, have been relieved with the aid of a perfect memory. In some cases the vision has been reduced to perception of light from scars on the front part of the eyeball. Perfect memory brings about the absorption of such opacities. A perfect memory has cured these obstinate cases.

Conical cornea is a very serious disease. Neither operation nor the use of drugs relieves or cures it. A perfect memory gives instant relief, the curvature of the cornea becomes normal, and the patient obtains normal vision.

Glaucoma has been referred to as a very treacherous disease of the eye, because symptoms of blindness may become apparent at unexpected moments. The pain of glaucoma may be very severe. In most cases, the eyeball becomes very hard. The vision fails in a few hours, and all perception of light may be lost. These very severe cases are usually not benefited by operation nor drugs. The practice of a perfect memory has relieved all the disagreeable symptoms, and the vision has returned to normal.

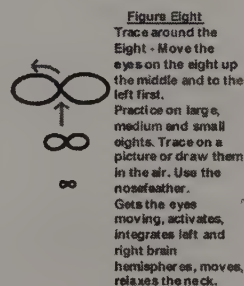

There are patients who suffer from paralysis of one or more of the nerves connected with the eye. By resting the nerves or the muscles to bring about a condition of relaxation, which is best obtained by a perfect memory, the symptoms of paralysis are relieved. Paralysis of the nerves of the eye is caused by too great activity and is relieved by relaxation.

When one of the eyes has been injured or has a foreign body in the inside of the eyeball, the good eye may become affected and, in rare cases, may even be lost before the eye that has been injured is lost. This is called **sympathetic ophthalmia**. Through the use of the perfect memory, these cases, although of many years' duration, have been benefited and normal vision obtained. To be able to demonstrate a perfect memory habitually or unconsciously, it is necessary first to consciously remember with the eyes closed or open one thing perfectly, until an unconscious habit is formed.

A person can remember what his own name is without having a mental picture of each letter of the name. This is an example of what is known as an abstract memory. A concrete memory is a more perfect memory, because one remembers a mental picture of the object with the eyes closed, as well or better, than he can see it with the eyes open. One can remember perfectly only that which is seen perfectly. When a letter is seen perfectly, the whiteness of the card or page in the neighborhood of the black letter is imagined whiter than the rest of the card or page, or that part in which there are no black letters. The whiter that one can imagine the white in the neighborhood of a letter, or inside of the letter, enables one to see the blackness of the letter blacker than before. In other cases, where the whiteness in the neighborhood of the letter is apparently of the same whiteness as the rest of the card, the memory or the imagination of the black letter is imperfect.

Mental pictures are imagined perfectly when the memory is perfect. A great many patients complain that they are unable to remember mental pictures of the letters of the Snellen test card. They can remember what the letters are but have no mental pictures of them. To obtain perfect mental pictures, it is necessary that the sight should be continuously good. Most people, when they fail to imagine mental pictures, try to remember too much at once. When remembering a letter, it is not necessary to recall all parts of the letter. The memory of the color or one small portion of the letter is sufficient. The smaller the part of a black letter that you remember, the blacker it is, and the easier it is to recall. It should be emphasized that when one has a perfect memory, central fixation can always be demonstrated. When central fixation is absent, the memory of the letter, as well as the imagination or the sight, is always imperfect. One can regard a point or a small part of a letter by central fixation for only a short time, not longer than a few seconds, without the memory becoming imperfect. **Shifting is necessary to maintain a perfect memory**, which is continuous. In other words, when practicing central fixation, the point regarded changes frequently. Shift from part to part on the letter and the memory, mental and visual picture of the letter is clear.

After a demonstration that central fixation is necessary for a perfect memory, one patient became able to imagine, with his eyes closed, a small letter "O" with a white center as white as snow, starch, or any other white object that he had ever seen. He had no trouble in doing this. He said that he could remember it easily and quite continuously. Then I requested him to remember an imperfect "O," which was a shade of light gray instead of black. It had no white center, but was covered with a blur or a fog. He was able to remember it quickly, easily, for a few seconds, but when he was requested to remember the imperfect "O" for a minute or longer, the gray shade became darker and, at times, lighter, and the memory of the imperfect "O" became very difficult. In spite of all the efforts he made, he was unable to remember the "O" continuously. In strong contrast to the memory of the perfect "O" the memory or the imagination of the imperfect "O" was difficult. He agreed with me when I told him that in order to fail to see perfectly, he had to stare, strain, and make a tremendous effort. On the other hand, the memory or the imagination of the perfect "O" was spontaneous, easy, and continuous, and he experienced a feeling of general comfort in all his nerves. He was able to demonstrate that he could remember the perfect "O," provided he imagined it was moving, and that he could not remember it when he tried to

imagine it stationary.

O is moving = The eyes are moving, shifting on the O.

Flashing is a great help in improving mental pictures. With the eyes open, one may see a letter quite perfectly and have a mental picture of that letter with the eyes closed for a fraction of a second. By repeatedly flashing the letter in this way, the mental picture becomes more frequent and lasts longer. When the sight becomes more continuously good, the memory is also benefited, and with this improvement in the memory, the mental pictures become more perfect. The converse is also true. When the memory is improved, the sight is improved. You cannot have a perfect memory by any effort or strain. The more perfect your memory, the greater is your relaxation, and the more perfect is your sight.

Memory, imagination, relaxation, clarity of vision function together, strengthen, improve each other.  
Practice on eyechart letters and any objects at close, middle, far distances.

## Stories from the Clinic

No. 72: JANE

By EMILY C. LIERMAN

A YEAR ago, a little girl named Jane, aged twelve years, came to me for treatment. She had worn glasses approximately four years for progressive myopia. Progressive near-sightedness is a very serious disease, in which the sight becomes worse more or less rapidly. With the increase in degree of near-sightedness, the retina becomes inflamed, and the vision is ultimately lost. This disease cannot be relieved by glasses nor by any known method of treatment, other than that recommended by Dr. Bates. Jane was also troubled with astigmatism.

When I first saw her, I was deeply impressed by her personality. She had unusual intelligence. Her parents were willing to make any sacrifice in order that Jane might be cured without glasses. She loved music but was ready to give it up temporarily, so that she could faithfully practice the daily treatment outlined for her.

When her vision was tested, she read 15/70 with the right eye and 15/50 with the left. After the first treatment, her vision with each eye improved to 15/40. The circular swing, which has proved so helpful in the cure of many patients, was her main treatment at the first visit. In this swing the head and eyes move in the orbit of a circle. They move continuously, and there is no opportunity to stare nor strain, as there may be when the head and eyes are just moved from side to side. The diameter of the circular swing should be as short as possible, because the greatest degree of relaxation can be obtained if **a short circular swing can be practiced**. There is this objection, however, that when the orbit of the swing is short, the patient may unconsciously stop the swing, and a stare or strain results. In a circular swing, in which the diameter of the circle is longer, relaxation is always obtained. The circular swing can be practiced with the patient standing or sitting. The results vary from time to time. At one time, the greatest benefit may be obtained while the patient is sitting, at another time while he is standing.

 ...and even smaller- do a fine print circular swing. (This diagram is a Circular Elliptical swing.)

 - Do the Modern improved version: Infinity Swing, Figure eight.

Draw the figure eight in the air with the eyes. Draw with the eyes and Nosefeather. Draw with the entire body, combined with the Long Swing: eyes, nosefeather, hand, entire body moves as the eyes, hand traces around the imaginary figure eight in the air. The figure eight can be drawn large in the entire visual field and smaller sizes, down to the size of tiny fine print. Move the head/body with the eyes. The neck is relaxed and mobile.

See [www.clear eyesight.info](http://www.clear eyesight.info) and picture, directions end of this book.

The infinity swing relaxes and brings movement to the eyes, head, neck, body, activates and integrates the left and right brain hemispheres, coordinated eye movement, improves balance, coordination and produces clear vision at all distances.

Having worn glasses steadily for four years, it was not so easy for Jane to go without them in the beginning. The second time she was treated she complained of a headache. This was immediately relieved by the circular swing, and her vision improved to 15/20.

After this visit, she practiced the treatment at home for six months or longer, but she never failed to report the condition of her eyes.

About a month after her first treatment, her vision for the test card had improved to 15/10. In the treatment, we used a card with numbers, another with E's pointing in different directions, which is called Pot Hooks, and still another with different letters. She found no difficulty in reading all the letters and figures on these cards at fifteen feet. It was noticed, too, that her little nervous habits disappeared. I gave Jane several treatments, and in all her eye tests, she did not make a single mistake.

Her mother decided to try test cards unfamiliar to Jane, because she had memorized all the letters of the other cards, and so purchased a test card at an optician's office. As Jane tried to read the card, she strained her eyes and became very uncomfortable. So did I. The only letter that did not make me strain was the large letter at the top of the card. This is seen by the normal eye at 200 feet. All the other lines of letters were so closely set together that they seemed like a herd of black sheep. My head began to ache as I tried in vain to separate each letter in order to read the card. It could not be done. Before I asked Jane to palm, I reminded her of a figure five on the familiar "C" test card, which she had memorized. Her mind was then relaxed, and we were able to proceed further with her treatment. As I palmed with her, my mind drifted to the test card which her mother had purchased. Mentally, I tried to separate the letters as I would separate sheep, in counting them as they followed each other over a stile\* or fence. The harder I tried, the less successful I became with my mental picture. Instead of imagining the sheep jumping over a fence or stile, one by one, I could only imagine them going over a precipice\* altogether and falling over each other in doing so. This produced a pain in my head and eyes, which I relieved instantly by the sway of my body from side to side, seeing objects about the room, moving opposite to

the movement of my body. My advice to Jane's mother was, not to use that test card for practice at any time.

Other test cards, unfamiliar to Jane, were then used. I placed Jane thirty feet away from the card and without any hesitation or one mistake, she read every letter. She did not have to be reminded to blink her eyes regularly, because it had become a habit. Blinking helped so much in keeping her relaxed. Our small fundamental test card, pocket size, was then used. We placed it in a good light, and Jane surprised me by reading the R Z 3 line at six feet. This is read by the normal eye, at three feet.

This article ought to convince any patient that progressive myopia is curable. It should encourage those who have given the method a trial, to keep on practicing as Jane did and win out as she has. At no time have I met a more wonderful child. She loved to practice the method every day. I shall always remember the last precious hour I spent with her. Her last words to me were:

"There is one thing I am certain about and that is: None of my children, nor grand children, nor great grand children need ever wear glasses."

\*Stile = Steps for crossing a wall or fence.

\* Precipice = A extremely steep mass of rock, cliff..

## The Magic Kitten

By GEORGE M. GUILD

ONCE upon a time a small black kitten strayed about the streets. The city seemed a huge world, peopled with giants, who pushed and shoved him here and there. He tried to escape them, but their enormous feet seemed everywhere. Finally, he came to a crooked alley, which was quiet and peaceful. He crept behind an ash barrel, glad to be away from the terrifying crowds. He grew drowsy and was falling asleep when suddenly a loud crash sounded in his ears. His heart began to pound faster and faster, and he wondered what would happen next. He was so frightened that he could not move. When nothing happened his fear left him and, like all little kittens, he became curious. He poked his nose from behind the barrel, but could see no one. Then he grew very bold and jumped to the top of the barrel, where he saw only a broken flower-pot with some faded roses scattered among the fragments. With his paw, he gently touched one and then another of the faded blossoms. They all seemed to move. He jumped down, and in his excitement pushed one to the ground. He ran a little way off and then cautiously approached to look at it.

Slowly the petals unfolded. In the center appeared a tiny golden fairy waving a beautiful wand. She danced gaily upon one of the petals and beckoned to the little kitten to come closer. He was frightened, but he felt a magic power drawing him nearer and nearer. As he came toward her, she bent over and gently touched him with her wand.

How strange he felt! Happy and contented, not like the little stray kitten that stole about the streets looking for shelter.

"Now you are a beautiful kitten, golden as the sun. Gone is the ugly, black creature that you were. Favored of the fairies, scamper away and make others happy as I have made you!" Saying this, the fairy hopped into the center of the flower, and the petals folded about her.

The kitten ran off as fast as he could go, to carry out the bidding of the fairy. Soon he came to a group of boys and girls at play. The children stopped their games to look at the little golden kitten. As they crowded about him he danced merrily, swinging his tail in time with his steps. The children clapped their hands with glee. The more joyous they became, the more sprightly did he dance.

Suddenly he stopped before little Eppie who had been trying to see him dance. Poor little Eppie's eyes were crossed, and it was difficult for her to see anything, even with her spectacles on. The kitten began to sway rhythmically from side to side. Eppie watched him without moving her eyes. She tried so hard to see him, and stared so much that he seemed only a blur of gold. She wanted to see him so badly, but the more she tried, the less she saw. Finally, Eppie could no longer keep back her tears. Seeing her tears, he danced over to her and gently touched her with his paw. As she bent over to pet him the magic kitten reached up and pulled off her glasses and let them fall to the ground. He stood up on his hind paws, grasped both of Eppie's hands and began to sway slowly from side to side.

He then dropped her hands and scampered off a short distance. Eppie followed him and looked down into his shining eyes. He kept blinking up at her, looking very wise. Eppie blinked back at him, and all at once she realized that she could see him perfectly. He turned three somersaults in the air, landing gracefully on his feet, and stood before her swinging his beautiful tail. Eppie watched the movement of his tail, swaying her body in rhythm with it.

The children all cried: "Oh, look at Eppie's eyes! How straight they are, and she hasn't her glasses on, either!" Then, they, too, started to sway from side to side, as they watched the swinging tail of the golden kitten.

By this time it had grown dusk and the children had to go home. They all wanted to take the kitten home, but he clung close to Eppie. When the other children tried to touch him, a tongue of golden flame shot from his mouth, and they quickly withdrew. Eppie held him tightly in her arms and ran home to tell her mother and father the glad news.

Before she had a chance to tell them all about her wonderful experience, they cried out in amazement at her changed appearance. Eppie told them breathlessly about the magic kitten, and what it had done for her. At the mention of him the kitten jumped out of her arms and began to swing his golden tail. With one accord, they all swayed in time with its motion. And so they became very jolly and happy.

The next morning, when Eppie awoke, the kitten had disappeared. Disappointed, she set out for school. Much to her surprise, there at the door of the school-house stood the golden kitten, waiting for Eppie. He ran ahead of her and jumped up on the teachers desk. He stood there swinging his tail to and fro.

The children, who were waiting in their seats for the arrival of the teacher, took great delight in the kitten's performance. They felt impelled by his mystic power to sway in time with the swing of his tail.

In the midst of their merriment, the teacher entered the room. The children stopped in fear, but the magic kitten became even more animated. The teacher approached her desk, and as she leaned over to see the kitten, her glasses dropped off her nose and broke in a thousand pieces upon the floor. She became angry and was about to throw the kitten from the desk, when she, too, felt the magic power of his swinging tail. In spite of herself, she swayed from side to side. Her anger left her, and she forgot her broken glasses.

The children looked at her in amazement, for they or anyone else had never seen her without glasses. The teacher was just as amazed as the children, for she suddenly became aware that she could see her class clearly. She was as joyous as the children had

been.

"Surely this must be the magic kitten we read about yesterday!" she exclaimed.

While she was speaking the kitten jumped down from the desk, flourished his tail and disappeared. The children were dismayed, but the teacher said: "Even though the magic kitten has gone, we shall always remember what he has taught us. We will set aside a time each day to practice the swinging movements of the magic kitten."

## Cases Benefited

By DR. CLARA C. INGHAM, Portland, Oregon

**CATARACT:** A lady sixty-five. Vision of right eye 20/200; left eye 20/100. Unable to do any reading. Six months treatment gives vision 20/20. Can read diamond type print.

**STRABISMUS:** Child of ten years. Vision 20/40. After eight months' treatment, vision is normal and eye straight. College student afflicted from childhood with extreme strabismus and oscillation. One of the most difficult cases for correction that ever entered my office. Sight in strabismic eye 2/200; in the straight eye 20/50. At the present time the oscillation has practically ceased while the strabismic eye is straight much of the time. Patient still comes about twice a week and while not yet normal, the vision of both eyes is greatly improved. This young man's mother is a teacher in the schools, and her son's restoration has done much to place Dr. Bates' Method before the schools.

**PAIN:** Patient a man of thirty-two. Vision 10/200. Severe pain in eyeballs and temples. Eye troubles from childhood. Says he was never conscious of absolute freedom from pain. After a year's treatment, is one of our greatest enthusiasts for good eyesight. He is an instructor in a college and will gladly spread the gospel.

**NEAR-SIGHTEDNESS:** Grammar school girl about fourteen, near-sighted from straining to see the blackboard. Vision in right eye 10/100; in left eye 10/70. After two months normal sight, and has learned how to protect herself against eye strain in school, so has no fear of a recurrence of the trouble.

**ACUTE GLAUCOMA** in right eye, the left eye having been completely lost its sight by the same disease more than a year previous. The right eye responded very readily to treatment, as has the left also, though seemingly past help when the patient first came.

## Eyestrain

By W. H. BATES, M.D.

EYESTRAIN is the cause of many serious diseases of the eye. It is always manifest when imperfect sight is present. The normal eye does not ordinarily have eyestrain. When it is acquired, the sight always becomes imperfect. When the sight is imperfect the eyes are under a strain. They are staring,—making an effort to see. This condition is not cured by glasses. The fact that wearing glasses always increases eyestrain can be demonstrated.

After treatment has been instituted, it is soon found that the use of eye-drops or drugs is of no avail. Bathing the eyes with a solution of boric acid or other similar remedies does not give the desired results. Attention to general health, physical exercise, and diet does not relieve symptoms of eyestrain. It is commonly a chronic condition. Patients who are suffering from this malady have usually acquired a habit of continually making an effort to see. One cannot correct this bad habit of strain without substituting in its place the beneficial habit of practicing relaxation continuously.

Good nutrition, exercise/movement, muscle massage (especially shoulders, neck), correct posture, correct use of the eyes (shifting, central fixation...), improves the clarity of vision, when combined with removal of eyestrain, mental strain.

The normal eye is always moving. To demonstrate eyestrain, one must first imagine the eyes stationary or actually force them to be stationary. This should prove to the patient that the eyes are under a strain when stationary, or when objects are imagined to be stationary. The normal eye maintains the habit of relaxation,—of always moving. When the eyes move, stationary objects are imagined to be moving in the direction opposite to the movement of the head and eyes. When the normal eye has normal vision, the head and eyes are continuously moving. This is a rest to the eyes, and a habit which can be more easily practiced than the habit of straining the eyes in an effort to keep them stationary.

Many people state that they have no time to practice the method which will bring about relaxation. This objection is answered by the fact that everyone has as much time to use his eyes correctly as he has to use them incorrectly. When the eyes are used correctly, the patient feels more comfortable, which should encourage him to use his eyes properly. When the eyes are not used correctly, discomfort is felt. Pain, fatigue and other nervous symptoms are produced.

Subjective conjunctivitis is a very painful symptom of eyestrain. The eyes burn and smart and the patient suffers from pain, fatigue, and many other disagreeable sensations. Later the eyelids become inflamed.

In the year 1884 I roomed with a young medical student who was suffering from this form of eyestrain. During the examination period he could not read more than five or ten minutes before his eyes became so sore and painful that he was unable to read at all. His physician prescribed a spray which had no apparent benefit. Another doctor prescribed flesh gloves (Misprint? Should be gloves...?) to be used in rubbing the skin all over the body. He derived temporary benefit from this treatment, but it had to be repeated at frequent intervals. It seemed to me at the time that the eyestrain was relieved by the massage, but a more thorough observation later proved that this was untrue. The relief was manifest when the massage was delayed or postponed, or when he had

rested his eyes.

One evening while I was reading he said to me: "Why do you blink so often?"

"Because it is an easy way to rest my eyes," I answered.

He practiced blinking and obtained complete relief. "My eyes are cool and comfortable, my sight is perfect, and best of all, I can remember what I read more easily," he stated.

We investigated the facts. He demonstrated many times that when he read without blinking the symptoms of eyestrain soon appeared, and his vision became worse. Other students tried it as well, and we all were positive that staring or trying to see without blinking always caused eyestrain. When the blinking was practiced relief was always obtained. There were no exceptions.

## Questions and Answers

Q—It is difficult for me to find time enough to gain perfect relaxation. What would you suggest?

A—You have just as much time to relax as you have to strain. Practice relaxation all day long. Whenever you move your head or eyes, notice that stationary objects move in the direction opposite to the movement of your head or eyes. When walking about the room or on the street, the floor or pavement appears to come toward you, while objects on either side of you move in the direction opposite to the movement of your body. Remember to blink frequently just as the normal eye does. Constantly shift your eyes from one point to another, seeing the point regarded more clearly than all other parts. When talking with anyone, do not stare. Look first at one eye and then the other, remembering to blink. Shift from the eyes to the nose, to one cheek and then to the other, then to the mouth, the chin, and back to the forehead.

Q—Why is it that I have perfect vision only in flashes? Can these flashes become permanent?

A—You have not yet lost your unconscious habit of straining. When relaxation methods are practiced faithfully at all times, the flashes of improved vision become more frequent and last longer until the vision becomes continuously good.

Q—What causes twitching eyelids?

A—Strain causes twitching eyelids and is relieved by rest and relaxation. Palming, sun treatment, swinging, blinking are very beneficial.

Q—Can you explain why I see yellow and blue spots after looking at the sun?

A—You are straining. Do not look directly at the sun until your eyes are more accustomed to it. Practice the sun treatment—sit in the sun with the eyes closed. Allow the sun to shine directly upon your closed eyelids, as you slowly move your head a short distance from side to side. Do this for half an hour or longer as often as possible whenever the sun is shining.

Q—Is working or reading under electric light harmful? Should a shade be worn?

A—It is not harmful to read by electric light if the eyes are used properly. Do not wear a shade or any other protection for the eyes. Practice sun treatment.

Q—When remembering a black period, I see a bright disk with a small black center. Is this seeing a period?

A—No, you are straining. The period that you imagine is very imperfect, because to remember the period, and at the same time a very bright disk, is an unconscious strain. You cannot strain and remember the bright disk, and simultaneously relax and remember a black period. When your bright disk is prominent, everything else is remembered under a strain. You cannot strain and relax at the same time.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND  
CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MARCH, 1926

Demonstrate

THAT **CENTRAL FIXATION** improves the vision. The normal eye is always at rest and always has central fixation. Central fixation cannot be obtained through any effort. When an effort is made by the normal eye, central fixation is always lost. In central fixation, one sees best the point regarded while all other points are seen less clearly.

Look at the upper left hand corner of the back of a chair. Note that all other parts of the chair are not seen so well. Look at the top of a letter at a distance at which it can be seen clearly. Then quickly look at the bottom of the letter. Alternate. When the eyes go up, the letter appears to move down. Then the eyes move down, the letter appears to move up. Coincident with this movement, you can observe that you see best the point regarded and all other points less clearly or less distinctly. When you can imagine the letter to be moving, it is possible for you to see best where you are looking.

The size of the letter or object seen, does not matter. Central fixation can be demonstrated with the smallest letters which are printed, or the smallest objects. Close the eyes and remember or imagine how the small letter would look if you imagined one part best. By shifting from one part of the letter to another, central fixation with the eyes closed may be made continuous for one-half minute or longer. Then with the eyes open, it is possible for one second or less to see, remember, or imagine the same small letter or other objects in the same way,—one part best.

### Central fixation and shifting

Look at the upper left corner of the chair. Shift on that part.

That part is in the center of the visual field and is clearest. Other parts of the chair are in the peripheral field and are less clear.

When the eyes move to a new part, the new part moves into the central field and is clearest.

Shift part to part on the chair and see one part at a time clearest.

The entire chair is seen clear.

Now practice on a letter.

Look at the top, then the bottom, then top, bottom, top...

See the letter move opposite the shift of the eyes. Shift left and right, any direction.

See one part best at a time.

Shift on a small letter and see one part best at a time.

Shift on a small part of the small letter and see one tiny part (small point) of the small part clearest at a time. See a small opposite movement as the eyes shift point to point.

The exact center, clearest area of the visual field is the size of the pointed end of a pin. The eyes, central field can shift point to point on a very small part of a object and still see one tiny point clearest at a time.

E

Note that when the letters are read easily and clearly, they are always seen by central fixation, and relaxation is felt. Central fixation is a rest to the nerves and when practiced continuously, it relieves strain and improves the vision to normal.

## Imagination

By W. H. BATES, M.D.

*Imagination is good. One may even see the white part of letters whiter than it really is, while the black is not altered by distance, illumination, size, nor form of the letters.*

**IMAGINATION** is good in normal sight. When the sight is normal, the imagination is normal. The converse is also true,—when the imagination is normal, the sight is normal. A cure is obtained when the imagination is improved to the normal. One may imagine a letter of the Snellen test card very well, while regarding it, with the eyes open. When the sight is normal, the imagination may be as good and usually much better with the eyes closed than with the eyes open. When the sight is perfect, one can imagine with the eyes open, objects of all sizes and forms, familiar or strange, just as well as he can with the eyes closed. Under favorable conditions of environment, namely, light, distance, and restful surroundings, the imagination is usually good. A perfect imagination can only be obtained when the memory is perfect. When the memory is perfect, the consciousness of the movement of all things remembered or imagined can always be demonstrated. The eyes are constantly shifting when the imagination is good. After the shifting stops, the perfect imagination is modified, or lost.

It is not possible to have a perfect imagination and an imperfect one at the same time. For example, one cannot remember a black color perfectly black, and a white color imperfectly white simultaneously. When a black letter with a white center is imagined perfectly, both the white and the black are perfect. It is impossible to imagine the letter with a perfect white center and an imperfect or gray-black outline. When the imagination is perfect for one thing, it is also perfect for all things. When a patient makes his first visit, the vision of each eye is tested for the Snellen test card at about fifteen feet. If the large letter of the Snellen test card cannot be distinguished at this distance, the card is brought closer until the letter is clear enough to be recognized. Experience has demonstrated that trying to improve the vision of such patients at fifteen feet or further is disappointing, but when they practice with the card at ten feet or nearer, the vision usually improves immediately. Some near-sighted patients have good sight at six inches, but not at twelve inches. By having them read as well as they can at six inches and then look at the card at twelve inches for a moment, the vision usually improves. Some patients can see very well at five feet for a short time. They are instructed to always close their eyes when their sight becomes imperfect, and when they open them, to keep them open for just a moment or a flash. This alternate resting the eyes by closing them and looking at the letters just for a second is a benefit to a great many. There are, however, a large number of patients who are not benefited at all by this method, because as soon as they open their eyes or even before that, they stare or strain and make an effort to see.

It helps very much to suggest to the patient that he use the word "imagination" and not the word "sight." To most people, to improve the imagination seems easier than to improve the sight, and quite a number believe that when they know what the letter is, although they may not see it, they can always imagine it. It is interesting to observe that when the imagination of a letter is improved by resting the eyes, other letters on the card not regarded become blacker and the whiteness of the card whiter. It is frequently demonstrated that one of the best ways of improving the sight is to improve the imagination of letters that are known. Often a patient says that he can imagine a known letter and sometimes thinks that he sees it, but he and his friends are usually very suspicious of the vision obtained when regarding a familiar card whose letters are known. It is necessary to demonstrate in various ways that when the imagination is improved, the vision is improved. This statement, however, does not convince the patient. The only test that is convincing is to test the patient with an unfamiliar card. It is oftentimes quite a shock to him to find that he can quite frequently read an unfamiliar card with much better vision than he is able to imagine or see the card that was familiar.

If a patient is unable to read fine print at twelve inches from the eyes or nearer, great benefit is derived from imagining the white spaces between the lines to be whiter than the rest of the card. When the white spaces are imagined perfectly white, the black letters are imagined perfectly black. When the imagination of the white is perfect enough, the imagination of the black letters is also sufficiently perfect, so that the letters are read easily without effort or strain, and without consciously looking at the letters. It is good practice to have a patient decide to imagine the white spaces perfectly white. If the letters improve, one should not try to read them. It is exceedingly difficult for most people to do this. With the slightest improvement in the white spaces coincident with a corresponding improvement in the blackness of the letters, the temptation to forget the white spaces and try to read the letters is very great. If one is unable to confine his attention to the white spaces, improvement in the ability to read may be very slow or impossible. To play the game, one must play it fairly and not be in a hurry to read the fine print when the imagination of the white spaces improves. In some cases it is well for the patient to close the eyes and remember the whitest white he has ever seen. This may be white snow, a white pillow, or whitewash. Then open the eyes and flash the white spaces, imagining them to be as white or whiter than the object remembered.

The imagination is not modified by the illumination. It is very interesting to find patients with good sight who can imagine things perfectly in a dim light. When this is accomplished, the clearness of all things seen, gives one the impression that the light has increased. For example, there are many people who, after the lights have been dimmed in the theatre, can read the program apparently as well as they can when the light is good. Patients with imperfect sight are troubled by the dim light more than are patients with normal vision.

Other environmental conditions affect the vision,—excitement of various kinds, unexpected noises and unusual occurrences. When some people go to a circus, they may become very near-sighted in a few minutes, although when attending a performance at the theatre, their eyes do not trouble them. Others cannot see well at the opera, because they are not accustomed to observing people's faces so far away, and yet on the street in all kinds of light they may have normal vision. When people with imperfect sight, try to find their way about in dark places, they strain their eyes to such an extent that they suffer pain, headache, and become exceedingly nervous. People with normal eyes and normal sight maintain a perfect imagination in strange as well as familiar places.

The normal eye is able to imagine the white centers of black letters whiter than they really are. Other people with imperfect sight

O  
e

Imagine a letter perfect -  
The white center pure  
white and the black ink  
dark black. Clear.  
When the letter is  
remembered, imagined,  
seen perfect, clear -  
all objects are  
remembered, imagined  
and seen perfect, clear.  
One of the first things a  
blind person regaining  
vision is taught, is to  
create, improve their  
mental pictures. The  
brain works with the  
eyes. Clear, familiar  
mental pictures of  
objects stored in the  
memory function with  
the brain to identify  
objects, create clear  
vision.

imagine the white center of a letter "O," for example, of the same shade of white, or less white than the rest of the card. The use of a screen helps such patients to improve their imagination. Use a card or piece of paper with an opening slightly smaller than the white center of the letter "O." Cover the black part of the letter with the card, exposing the white center. By alternately closing the eyes, resting them, the patient becomes able to see or imagine he sees the center of the "O" to be less white than it appears to be when the black part of the letter is exposed.

No patient is cured until he becomes able to imagine a letter at ten feet or further as well as he can see it at one foot or less. In this connection, it is well to emphasize the fact that the cure of imperfect sight can only be accomplished without effort. Too many patients believe that the cure of imperfect sight is very complicated, and that they have to make a great effort. It is only when they become convinced that the one way they can obtain perfect sight is by rest, or that when their sight is imperfect, a strain is necessary to keep it imperfect, that a permanent improvement, is obtained. A sufficient improvement of the imagination is a cure of imperfect sight. Patients with perfect sight have a perfect imagination of the things that they can remember. Patients with imperfect sight always have an imperfect imagination.

So many people look with contempt on the imagination, especially when it comes to treatment of the eyes. Most people do not associate imagination with perfect vision. They are of the opinion that they can imagine they see something without actually seeing it. This is not so. Perfect imagination and perfect vision are identical.

Of all the discoveries that I have made, there is none of so much practical value as the discovery of the importance of the imagination.

## Stories from the Clinic

### No. 73: MARGARET MARY

By EMILY C. LIERMAN

MARGARET MARY is not yet five years of age. Her mother told me that an eye specialist prescribed glasses for her when she was two years old to be worn constantly for the cure of **squint**, which she had contracted after an attack of whooping cough. The squint was alternate, sometimes the right eye turned in, at other times the left.

When I tested her sight at the first visit, October 24, 1925, the vision of each eye was one-fifth of the normal. She is an obedient child and did what I told her. At my request, she covered both eyes with her hands. I asked her to remember her dollie. She smiled and asked: "Which one?"

I answered: "Your best dollies"

I found that Mary had a good memory for colors. When I asked her what the color of her best dollie's dress was, she answered: "Pink." As she, herself, was wearing a blue dress, I tested her memory for colors by asking her if the dollie's dress were the same color as the dress she was wearing. She peeped between her fingers, looked at me and said: "No, my dress is blue." I asked her if the dollie had black shoes like hers. She answered: "No, she hasn't any shoes."

All these questions were necessary in order to encourage the child to imagine perfect mental pictures and obtain relaxation. After she had palmed five minutes, I told her to remove her hands from her eyes and look at the card. Her vision, when tested, had improved to one-half of the normal.

I taught the child how to sway her body from side to side, as I held her hands and moved with her. While we were doing this, Mary's mother looked on. She was amazed when the eyes became straight from the swaying. Then I told the mother how important it was to have the child practice the swaying several times every day. She has a victrola in her home, and I advised the mother to play a waltz, if possible, when the child was swaying.

When Mary returned a week later, I noticed that the squint was much better. She placed her arms about me and said she loved me, because I removed her glasses. I tested her sight and found that it had improved considerably. When she was reading the card for me, there were times when she sighed. This was a signal that she was tired. I would then lead her to the drawer in which some candy is kept. If parents do not object, I give my little patients some good candy, while they are practicing. In my experience, nothing has relieved eye fatigue in children so much as a little candy.

During a treatment, in which her eyes were perfectly straight, two boys came into the room. I watched Mary and noticed that her left eye turned in considerably. I immediately placed the boys in another room. When I returned and spoke kindly to Mary, her left eye became perfectly straight again. Her aunt, who had brought her, was amazed at the quick relief of the squint. It was very evident that the unexpected presence of the two boys had caused a strain which produced the squint.

Before she left me that day, her vision had improved to four-fifths of the normal. On January 16, 1926, her vision had improved to the normal with the eyes straight. Up to this time, we had been using the card with the letter E of different sizes pointing in various directions. As she did not know numbers, I taught them to her with the aid of a Snellen test card consisting of figures up to ten, while holding the card about one foot from her eyes. She was delighted with the change and her eyes remained straight all the time. Her joy was unbounded when I told her that she could take the card home with her.

One week later, she was able to tell every figure on the numeral card.

This case was interesting. The child had been wearing glasses prescribed by a competent doctor for two years without relief. The squint was not cured nor benefited by them, because it returned just as soon as the glasses were removed. Even while wearing them, the squint was usually evident, and the vision was not improved. A study of her treatment and the results, showed that the cause of the squint and the imperfect sight, was a nervous strain. Many children as well as adults can produce a temporary squint by a stare or strain.

Investigation has proved that this fact should be emphasized. For more than one hundred years, ophthalmologists have declared repeatedly that the imperfect sight of a squinting eye is usually incurable. Many writers make the statement that children are born with squint. In these cases, the blindness is usually more marked at the centre of sight, and yet, with the ophthalmoscope, the

Girl palms and remembers her doll, color of its dress... Opens the eyes and Echart letters are seen clear.

E

Perfect mental pictures, relaxation=clear vision.

Sway, dancing to music improves clarity of vision and straightens the eyes, gets them moving together.

centre of sight may look perfectly normal. One celebrated writer tried to explain the facts in a few words by stating that the blindness of squint was a condition in which neither the patient nor the doctor could see anything, meaning, as was stated above, that although the sight of the squinting eye may be very poor or entirely absent, the ophthalmoscope shows no evidence of disease of the retina. All cases of squint are cured by treatment which eliminates strain.

## Fundamentals

By W. H. BATES, M.D.

(Vision Impairment Caused by Eyeglasses, Sunglasses)

**1. Glasses must be discarded permanently** because it is a truth that one cannot be cured without glasses while wearing them, even occasionally. **Dark glasses** and other measures to protect the eyes from the strong light are also objectionable. **The eyes become more sensitive to light with a loss of vision.** Magnifying glasses lessen the clearness of all colors, including black and white. The size and form of objects are modified by all kinds of glasses. Glasses for the correction of far-sightedness may, and usually do, give the wearer the impression that objects are larger than they really are; while near-sighted patients when wearing glasses are impressed with the fact that objects look smaller than they actually are. Glasses for the correction of astigmatism may cause dizziness.

In wearing any glasses, it is necessary to look directly through the center of the glass in order to obtain maximum vision. If one regards an object by looking in a slanting direction through the glasses, its form and location are changed. Many people, when they first put on glasses, feel as though they were a long distance from the ground. With other glasses, they have the sensation of being shorter, or that the distance from their eyes to the ground has become lessened.

The discomfort of glasses is very great with a large percentage of people who wear them. Frequently, when they complain to their ophthalmologists, or to the opticians who supplied the glasses, they are advised that by perseverance their eyes will become fitted to the glasses. This does not seem quite satisfactory, because people feel that the glasses should fit their eyes, and not that they should struggle along with all kinds of discomforts in order to make their eyes fit the glasses.

**Tinted glasses, red, yellow, blue, green, or black**, when worn constantly, usually feel comfortable to the patient because the amount of light is lessened. At the seashore, when the reflection of light from the water affects the eyes badly, causing pain and discomfort of all kinds, the wearing of colored glasses is, for the time at least, often a great relief. However, constant wearing of such glasses is later followed by sensitiveness to the light and the necessity for stronger glasses to obtain a sufficient amount of relief. The protection of the eyes by dark glasses, shades, and other measures has caused inflammations of the eyeball and of the eyelids. Pure sunlight is necessary for the health of the normal eye, and when people live in dark rooms, they usually find their eyes are weakened.

The shape of the eyeball is changing frequently. Sometimes the eyes are focused for distant vision and other times for near vision. Glasses which correct the sight for reading, very seldom enable the patient to see at the distance as well as without them. On the other hand, near-sighted persons whose vision is poor for distance, when wearing glasses to enable them to see distant objects, find that their ability to read with maximum vision is impossible with such glasses. When the glasses do not correct the vision for all distances, the eyes strain and try to overcome the bad effect of the glasses. Without glasses, the eyes may strain, but the wearing of glasses increases the strain. Glasses correct the eye trouble to a certain degree, but when the eye trouble varies, or the strain varies, the glasses do not relieve the wrong focus of the eye at all times. For example, the glasses that correct the imperfect sight, or the strain of imperfect sight at ten feet, may not do it when the eye strains and is focused for a nearer point, or for a more distant point. Many people complain that they do not get relief from wearing glasses at all hours of the day, because strain and inflammation of the eyeball produced by the strain, is so variable. When the eye becomes normal, or when it becomes able, as the result of treatment, to change its focus without difficulty, the patient is comfortable and can only be comfortable without glasses.

**2. Central Fixation** is seeing best where you are looking, and at the same time seeing worse where you are not looking. The letters of the Snellen test card, when seen clearly, are always seen by central fixation. Diamond type, when read slowly, or when one letter is seen clearly, continuously, for part of a minute, requires central fixation.

Concentration is an effort to see where you are looking and not to see at all where you are not looking. This is impossible without a strain. An effort to concentrate always fails to improve the vision. All persons with imperfect sight try to concentrate. When the vision improves, the effort to concentrate becomes less. Persons with normal sight never try to concentrate. When thinking about something, it is normal for the mind to move from thought to thought: on the original subject, then to other thoughts, ideas connected to that subject, sometimes to other subjects, then back to the original subject. The mind uses mental pictures to think, a different picture for each thought. The eye does this; the eye looks at a object and shifts part to part on the object, then to other objects, then sometimes back to the original object. This is the normal function of the brain, eyes and produces relaxation (deep or active 'dynamic') and clear vision.

**3. Favorable Conditions:** Light may be bright or dim. Some persons are unable to see in a bright light. Their vision is usually improved by the sun treatment. They sit in the sun with the sun shining directly on their closed eyelids as they slowly move their heads a short distance from side to side. This is practiced for half an hour or longer whenever possible. The eyes are rested and strengthened, and gradually grow accustomed to the strong light of the sun. Individuals who cannot see so well in a dim light as in a bright light are benefited by the imagination of the halos, that is, the imagination of the centers of round letters to be whiter than the rest of the card. The memory of perfect sight also helps one to see in a dim light. By the memory of perfect sight is meant the ability to remember or imagine perfectly a letter or an object which has been seen perfectly.

The distance of the print from the eyes, where seen best, also varies with individuals. In some cases, the letter or object regarded and seen clearly, may be, as in near-sighted eyes, one foot or less from the face. To be able to see further off, requires practice. When things are not seen at a greater distance, two feet or further, the vision usually is improved by remembering one letter of the Snellen test card perfectly with the eyes closed. Then when the eyes are opened for a fraction of a second, it is possible to imagine (and see) the known letter at two feet or further.

Many middle-aged people can see well at twenty feet or further, but are unable to read the newspaper at two feet or nearer. The

same principle holds true in these cases, as in those of near-sightedness, except that the distance of the print from the eyes is gradually decreased until it is read without effort or strain at twelve inches.

**4. Shifting.** In normal sight the eyes are moving all the time. It is necessary when the eyes are at rest, that they keep moving, to avoid the stare. To stare, the eyes must be stationary. Shifting prevents the stare. When the sight is imperfect, the eyes strain or stare by regarding one point all the time. All patients with imperfect sight, when they look at a letter, see it stationary. They look at a part of the letter or the whole of the letter, and see it all alike. The vision always becomes imperfect when this is done.

Staring = eyes immobile, not shifting.

There are various ways of obtaining the habit of shifting. One has to first obtain the conscious habit. Shifting a long distance is readily accomplished, but when one shifts a very short distance, it is not always easy to be conscious that the eye really moves. One can be sure that the eye is moving when objects, not directly regarded, appear to move at the same time. No matter how great the strain of the eyes may be, it is always possible to shift a long distance, usually by turning the head in the same direction as the eyes move. The long shift is always some relief. When the shifting is shortened to one-quarter of an inch or less, when regarding small letters, the eye with imperfect sight may have difficulty in imagining the letter to be moving so short a distance. Near-sighted people who have good vision close to the eyes, at one foot or less, and can read the finest print, are able quite readily to imagine the eyes shifting as short a distance as the width of one of the small letters. The short shift is more difficult, but when it is successfully practiced, one obtains a greater amount of relaxation than can be obtained from the long shift. I wish I could emphasize the value of shifting.

About five years ago, a patient whom I had cured of near-sightedness some years before, called to see me. His vision was normal not only for a familiar card, but he could read with normal vision, letters of an unfamiliar card.

"Did you have a relapse?" I asked him.

He replied: "I have never had any relapse." "What do you think has cured you?"

His answer was: "Shifting."

**5. Swinging.** When the eyes move slowly or rapidly from side to side, stationary objects appear to move in the direction opposite to the movement of the head and eyes. Some people have a very painful and disagreeable time in becoming able to imagine that stationary objects appear to move when the eyes move. If one stares directly at a stationary object, it does not move. This suggests very strongly that one should not expect stationary objects to move when he looks directly at them. When one shifts a long distance from one point to another without effort or without strain, or without trying to see, it is possible to imagine stationary objects not regarded, to be moving. Some people tell me that when they look out of a car window of a railroad train, they do not imagine the telegraph poles to be moving opposite to the movement of the train. On the contrary, they feel that they are moving and do not like to imagine the illusion of the telegraph poles to be moving. One has to treat such patients with much ingenuity. One patient could imagine things moving while she was running, but not while she was walking. I had her run around the office one morning until she obtained considerable improvement in the swing, but the exercise produced blisters on both feet. Later, she became able to obtain the swing of stationary objects when she did not run so fast or so long. At first she practiced a fast walk, and then a slower walk until she became able to imagine stationary objects to be moving, by just moving her head and eyes.

See objects moving by doing the Long swing, Rock (Sway) - Long large oppositional movement.

Shorten the Sway to 4 - 1 inches and see shorter, smaller oppositional movement. See objects moving by shifting on small and tiny objects, fine print letter... - Short, small oppositional movement. Very clear vision!

Sunning - Face the sun, eyes closed and move the head slowly side to side.

Sunglass - Eyes closed. Head still. Sunglass with sunlight shining through the glass is moved quickly, 1-2 seconds on the eyelids.

Sunglass with eyes open - Head still. Eyes looking down, pupil under eyelid, away from the sun's light. Sunglass moves the sunlight quickly, 1-2 seconds on the sclera, upper white area of the eye.

Sunglass is used only in cases of blindness, by an experienced ophthalmologist, only when other methods have not helped restore the vision.

## Questions and Answers

QUESTION—When one uses electric light in place of sunlight—

- How strong a light is it proper to use?
- Because of the heat, how close to the light is it advisable to sit?
- How long is it advisable to sit at one time?
- How much time should be given to it in a day?

ANSWER—(a) One can use an electric light of 1000 watts with benefit.

- Sit five feet or further away from the light to avoid any discomfort from the heat.
- Practice for one-half hour or longer. The more light treatment taken, the better.
- Devote at least one-half hour a day to the sun or light treatment.

Q—Is the effect of the burning glass and that of sunshine falling on closed eyelids different, so that one needs both kinds each day?

Sunning and Sunglass Treatment

A—The sun treatment with the burning glass is more intensive than without it. At first, patients become accustomed to strong light by sitting in the sun and allowing the sun's rays to shine directly on the closed eyelids, as they slowly move their heads a short distance from side to side. Then, with the burning glass, the strong light of the sun is focused on the closed eyelids, and when the eyes are accustomed to that, one can consider the advisability of focusing the direct rays of the sun upon the eyeball, itself. This is done by lifting the upper lid while the patient looks down.

When the sun is focused upon the naked eyeball, one should keep moving the glass from side to side, and for a short time only, so as not to produce discomfort from the heat.

Q—If one practices reading fine print for a time each day, is it harmful to read print like that of the Forum (usual magazine type)?  
A—No, the more you read, the better, even though you read with imperfect sight. Large print can be read with a strain, but fine print can only be read when the eyes are relaxed. It is all right to read print of any size if one reads it with perfect sight. When read with imperfect sight, the eyes are under a strain. Imperfect sight is always caused by a stare or strain, and one can stare or strain when regarding a large letter, blurring it to a considerable degree, and yet be able to tell what the letter is. The same amount of strain, which produces as much of a blur, when looking at a small letter, may make it impossible for one to read the small letter perfectly, although he can still distinguish the large letters. **Any size type can be read without strain if blinking, shifting, and central fixation are practiced.**

Q—In viewing moving pictures is it not more beneficial to sit as far back as one may and not strain, than to sit farther forward?

A—Sit at a distance from the screen at which you are most comfortable, i.e., where you can see the picture with the least discomfort. One can strain the eyes when sitting at almost any distance from the screen. To avoid the stare and strain as much as possible, it is necessary to keep shifting the eyes from one part of the screen to another, or to look off into the darkened room from time to time to give the eyes a rest. Some people are benefited by palming for a few seconds or longer, and in this way prevent the strain.

Q—When palming and seeing mental pictures, I almost never think whether it is black before my eyes or not. If I turn my attention to it, it is usually dark, more or less, but not a black. Am I right not to think at all about it?

A—When palming, do not try to think of anything. Just think of something pleasant, something that you remember perfectly, and let your mind drift from one pleasant thought to another.

## RETARDATION NUMBER BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

APRIL, 1926

Demonstrate

**THAT the optical swing always improves the vision.**

Stand before an open window with the feet about one foot apart. Sway the whole body, including the head and eyes, from side to side. When the body moves to the right, the head and eyes also move to the right, while, at the same time, the window and other stationary objects are to the left of where you are looking. When the body sways to the left, the window and other stationary objects are to the right. Be sure that the head and eyes are moving from side to side with the whole body, slowly, without an effort to see. When the swaying is done rapidly, it is possible to imagine stationary objects are moving rapidly in the opposite direction. While the swinging is being practiced, notice that the window and other stationary objects which are nearer, appear to move in the opposite direction to the movement of the body, head and eyes. Objects (in distance) beyond the window may appear to move in the same direction as the body, head, and eyes move. (especially when there is a close object in front of the distant object)

Note that when the body is swaying rapidly, the window and other objects are not seen very clearly; but when the swaying is slowed down and shortened, so that parts of the window move one-quarter of an inch or less, the vision is improved for those parts of the window regarded. More distant objects, which move in the same direction as the movement of the body, head, and eyes, are also improved with the slow, short, easy swing.

After you have become able to imagine the window to be moving, practice on other objects. All day long, the head and eyes are moving. Notice that stationary objects are moving in the opposite direction to the movement of the head and eyes. To see stationary objects apparently stationary, is a strain which lowers the vision and may cause pain, fatigue, and other discomforts.

## Retardation

By W. H. BATES, M. D.

WHEN pupils in school fail to maintain the scholarship of other and normal children of the same age, their mental efficiency or their standing is said to be retarded. Such children may remain in the same low grade for several years with no apparent improvement in their scholarship, and are seldom promoted. The cause is rarely due to an impaired mentality. The fact that all of those observed have been benefited or cured by eye-mind education, is convincing evidence that retardation is functional.

Sway left and right in front of a open window. The window (close objects) move in the opposite direction the eyes, head, body move to. Distant objects move with the eyes, head, body in the same direction. Close and distant objects move against each other in opposite directions.

Sway shorter—1 foot or less; 1-2, 4 inches, move slower and see the close and distant objects move shorter and slower. When the sway is short the eyes can shift on a object, letter.

These illusions of stationary objects moving help the brain, eye, visual system determine: depth, distance, dimension, position, shape, size, time and other conditions of object as in the visual field. Helps distinguish between two or more objects, especially when the vision is blurry. This improves the vision and other brain, eye, body functions, movement, balance, coordination... Time = how long it takes to move to/from objects, speed of your movement...

If the eyes look at objects at a specific distance when moving left and right, the speed of the objects movement at different distances changes. Normally the eyes do not look at any objects when swaying long—the eyes just sweep across the visual field and let the objects swing, move.

### ***Imperfect Sight***

Imperfect sight is usually associated with retardation, which is very prevalent. When these cases improve, their vision always improves. One principal reported that all the school children in the rapid advancement classes under her jurisdiction had normal sight without glasses. In all the other classes the percentage of retardation was very high, and in some classes all the pupils were suffering with retardation. It was customary to separate the children whose retardation was extreme and put them all in one class under the control of one teacher. The teacher told me that after she had improved their vision, their scholarship advanced and they were transferred to the usual grades.

### ***Retardation Cure***

For many years, retardation has been studied by competent men; all sorts of causes have been ascribed to this condition, and remedial measures have been practiced which have heretofore not been of the slightest benefit. The method which I suggested was very simple. A Snellen test card was placed in the classroom in a place where it could be seen by all the children from their seats. Sometimes two or more cards were placed upon the wall. Every day for a short time under the supervision of the teacher, all the children read the card, first with one eye and then with the other, while one eye was covered with the palm of the hand in such a way as not to press upon the eyelids.

Modern left and right brain Hemisphere Activation and Integration methods and all Bates Method activities improve functions of the brain, left and right hemispheres; math, science, art, creativity, memory, imagination, sports, speech, social skills, clarity of vision.

### ***Benefits***

The teacher told me that the use of the cards in this way after a few weeks or months was followed by an improvement in the sight, when the retardation became less. One benefit of this practice was that it relieved or prevented headaches and other discomforts. The ability of the children to study was stimulated. The memory, imagination, judgment and other phenomena of the mind were very much benefited. It was also encouraging to note that, with the improvement in their retardation, a larger number of children continued in school than ever before. In the beginning, many of these children were so unhappy and so uncomfortable in school that they were usually anxious to stop school and go to work. After their retardation was improved and their vision benefited, they said that they could look at the writing on the blackboard and read it without discomfort. They also said that they could study without getting headaches. Furthermore, they seemed to become able to remember and understand what they read or what they studied.

### ***Truancy***

Truancy was very common among the children who were suffering from retardation. After the retardation was relieved or cured, truancy became very much less and the children volunteered the information that after they became able to read or study without discomfort, they could understand better the lessons that were assigned to them. Children who were very restless and mischievous, so-called bad boys or bad girls, became model pupils and very easy to handle.

### ***Stare***

The evils of retardation were numerous. The cause was always a stare, a strain, or an effort to see. The cure was accomplished by teaching the children how to use their eyes without staring or straining. While reading the Snellen test card in the way just described was a great benefit, there were other methods practiced by some children which were an added benefit. One teacher from the northern part of the State of New York was exceptionally good and was able to keep order in her classroom when other teachers failed. She wrote me that she always began the day by having the children palm, or cover both closed eyes with the palms of the hands in such a way as to exclude all light. This the children did for fifteen minutes and then they started in with their work, feeling rested and comfortable. When she noticed them becoming fatigued, she had them practice swinging, and the result was that they continued their work without becoming restless.

### ***Memory***

Another teacher, living in Chicago, found it an advantage to teach the children how to remember. This was accomplished in some cases by having the children remember their own signatures at first, as well as they could. They improved their memory by alternately looking at their signature and then closing their eyes while remembering it. The children were able to demonstrate that it was easier for them to remember one word of their signature than three or more words. They also found that they could remember one letter of their signature better than the whole word. By practice, they became able to remember a part of a letter better than the whole letter, and the smaller the part remembered, the more perfectly was it accomplished. Many of them became able to remember a small period perfectly black, as well with their eyes open, as they could with their eyes closed.

## Imagination

This teacher also improved the imagination of her pupils. Some one would read a story. Then all the children would palm and remember the story as well as they could. After opening their eyes, they would try to illustrate the story in various ways. The teacher sent me about forty illustrations, and I found them very interesting. They were unusual, but the teacher claimed that doing these unusual things was a great benefit to a large number of children who were suffering from retardation. Coincident with the improvement in the memory and the imagination, was a corresponding improvement in the sight. There were other benefits just as important in value.

## Adults

Adults also suffer from attacks of retardation. For example, a portrait painter may do good work for a longer or shorter period, but at intervals his work becomes decidedly poor, unsatisfactory, and a failure. Writers, financiers, inventors, teachers and professional people of all kinds, have attacks of retardation, when their mental efficiency is lost or impaired, usually suddenly, for longer or shorter periods of time.

## Automobile Drivers

It is an interesting fact that people who drive motor cars suffer greatly from eyestrain. Taxi drivers are under more or less of a nervous strain. I am very fond of talking to these people about their work, because, being very observant, they teach me a lot. Many of them have told me that when they had an accident, it was difficult for them to believe that it was their fault. At one time a taxi-driver ran into another, broadside on. There was quite a smash-up and a number of people were injured. The taxi-driver was not detained very long, and later he came to see me about his eyes. Among other things he said: "Doctor, I never saw the automobile that I ran into. I never knew it was there until after the smash. Do you think there is anything wrong with my sight?"

I tested him very carefully and found that his vision was 20/20 with each eye. I examined his eyes very carefully with the ophthalmoscope and finally I said to him: "You have perfect eyes, but you don't always see with them."

"What do you mean?" he asked.

"I mean this,—that while your sight is perfectly good usually, there are times when you become totally blind. Everybody with perfect sight does not have perfect sight all the time."

"Well," he asked, "what am I to do?"

After talking to him for a while and explaining what I meant by the stare, the strain, or trying to see, and how one always stared when one had imperfect sight, I told him that the remedy was to use his eyes in such a way that he did not stare. Riding all day long in a moving car, he should notice that the road in front of him comes toward him, while objects on either side of him, move in the opposite direction. In this way he would not stare so much and the attacks of imperfect sight would be eliminated.

Shift, notice oppositional movement to avoid staring, effort to see, strain, unclear vision, and to see other vehicles, objects when driving, sailing.

## Sailors

A sea captain called on me one day with a history of imperfect sight at irregular intervals. When his sight was tested with the Snellen test card at twenty feet, his vision was normal. I told him that he had perfect sight. I examined him with the ophthalmoscope and told him that he had perfect eyes. "Well," he asked, "why do I have those attacks of blindness when I cannot even see a big lighthouse, when I cannot see a large vessel coming towards me sufficiently clearly to avoid a collision?" I talked to him the same way I had to the taxi-driver and he, very grateful, left the office.

## Stories from the Clinic

### No. 74: RETARDATION

By EMILY C. LIERMAN

ABOUT seven years ago, a girl aged sixteen, was treated for a severe inflammatory trouble with her eyes. She was brought to me by her father. Her eyes were paining her continuously and her vision was very poor. To protect her eyes from the light, she was wearing glasses which were so thick that her vision was lowered to a great extent by them. The suffering of the girl was pitiable. It was impossible for her to do any reading whatever, and she had been compelled to stop school two years previously.

The first thing we did for her, was to give her the sun treatment with the aid of the sun-glass. Before she was placed in the sun, she was instructed to close her eyes and keep them closed until she was told to open them. She was then placed in a chair where the sun shone directly on her closed lids, while she moved her head continuously, a short distance from side to side. After ten minutes, her eyes had become somewhat accustomed to the sunlight. With a little encouragement, she succeeded in opening her eyes while looking far down. The upper lid of each eye was gently raised sufficiently to expose the white of the eye to the direct rays of the sun. Her eyes rapidly became more and more accustomed to the strong light, until she was able to stand the light focused in flashes on the white part of the eye with the sun glass. Her vision at times was 20/200. Best of all, she was able to open her eyes without discomfort. It seemed like a miracle. For the first time in two years, she was free from pain. Both she and her father were

very happy. Whereas, at the beginning, her father had led her in the room, she led him laughingly out, without the thick dark glasses on. Being of a nervous temperament she would, at times become hysterical as her vision improved, but after she was entirely cured, she seemed like a different person. Her nervousness disappeared and her manner was calm. As she became more accustomed to the strong light, her vision gradually improved to the normal.

Palming helped her very much. Imagining stationary objects to be moving whenever she moved her head and eyes, relieved or prevented the stare or trying to see. The memory or imagination of perfect sight enabled her, at the same time, to read the Snellen test card with normal vision, at first in flashes and later more continuously. The greatest benefit she obtained from the eye treatment, was that her mind became able to do things with much greater efficiency and her memory was decidedly improved. She became able to remember a small black object, or a small black period, as well with her eyes open, as she could with her eyes closed. Formally, when she read a page of history, she had to reread it half a dozen times before she could understand any page that she read. In three months time, her trouble had entirely disappeared; she returned to school and her friends and teachers were amazed at the great change in her. After her eyes were cured, she read the pages in her history book only once, and not only grasped the meaning but also was able to remember it for six months or longer without having to read it again just before examination time. At one examination, the questions were written on the blackboard and, after she read them, she was shocked to find that she could not answer a single question. Fortunately, she remembered her eye treatment and the little black period. With the help of palming, swinging, and the memory of perfect sight, she remembered the answers to all the questions.

This experience that she had, is very valuable because she was cured of an attack of retardation by simple methods which could be employed in all schools, colleges or elsewhere in the business world.

The principal of this school visited Dr. Bates to learn more about our method of treatment and also placed herself under his care until she was cured without glasses. She had been wearing them for presbyopia.

Some years ago I wrote about a group of children who were suffering from retardation. Their teachers could not understand so many failures. After it was discovered that they had imperfect sight, the school nurse sent them to the optician to be fitted for glasses. Later, it was noticed that even though they were wearing glasses, the retardation still continued. A little girl from the same school, who wore glasses, came to our clinic and was cured without them. She encouraged other children to come to us. Part of this large group of children who came were the "Wild Indians," I wrote about in my book, "Stories from the Clinic." The little girl who encouraged them to come, was a very good assistant for she knew exactly how to start each one with the treatment. With her help, all of them were cured without their glasses.

This happened in the Spring when the thought of being promoted was uppermost in their minds. Through one of their teachers, who was cured of her myopia by Dr. Bates, I learned that all were promoted with the exception of one little boy. Not one mother of any of those dear children was any happier than I, when they brought the joyful news to me. I was proud of my work and proud to tell it, too.

During that vacation, two public school graduates, who were under treatment for their imperfect sight during the previous Spring and had obtained normal vision, told me how they had successfully passed all their tests. One of them said, "If it had not been for the memory of a little swinging black period which I never forgot, I am sure that I would have failed." The other graduate said, "I did not need to remember anything in particular when the tests were easy, but you bet I never forgot the movement of a small black period when the test was difficult."

I believe retardation will no longer exist when imperfect sight is avoided and eye-glasses are a thing of the past.

## Retardation

By M. F. HUSTED

Superintendent of Schools, North Bergen, N. J.

It has been found by educational experts that certain norms for the Age-Grade location of pupils should exist. Pupils above this age for the grade are classed as Over-Age for their grade and pupils of this age are classed as Normal Age and pupils below this age are classed as Under-Age. Classes, schools and school systems are considered in good condition when the number of over-age pupils does not exceed the number of under-age pupils. It is considered by administration experts that this standard test of a school system affords the best single test of the value of the school work done. The normal ages are determined by expert educational authority to be used as follows:

Grade	I	II	III	IV	V	VI	VII	VIII
Normal Ages	6-7	7-8	8-9	9-10	10-11	11-12	12-13	13-14

Pupils who are over this age are known as "Retarded" or as "Repeaters."

### REASONS FOR RETARDATION

1. All experience shows that "All men are" not "created equal."
2. Parents change places of residence and pupils change schools. These pupils are not promoted at the end of the term, as are pupils who have spent the entire year in one school.
3. Ill health of a pupil or in a family, irregular attendance, prevents the receiving of the usual amount of instruction.
4. Entering school so late as to produce over-age.
5. Misfits for a grade for a time—those who do not speak English.
6. Changes of teachers are too frequent.

7. The quality of teaching is too low because teacher-training is too little.

#### NATIONAL EDUCATIONAL ASSOCIATION MEETINGS

The Boston National Educational Association Meeting in July, 1910, which the writer attended, contributed the following: "Children who make rapid progress (underage) through the grades shall at least equal in number those who make slow progress (over-age). At the present time this condition does not exist commonly, if indeed it does anywhere. It is probably a most conservative statement to say that in the average city there are at least ten times as many children making slow progress as there are making rapid progress. *To change this condition is the great school problem.*

"Develop and perfect measures:

1. For conserving and increasing the physical soundness of pupils.
2. For discovering and excluding cases of contagious disease.
3. For finding and having remedied physical defects.
4. For making the entire school and its surroundings happier, healthier and more wholesome.
5. For that sort of record-keeping that shall enable the school to keep track of each individual child from the time he enters school until he leaves and to tell *when he fails and why he fails and guide in preventing him from failure.*
6. For changing our courses of study or our methods of grading and promotions so that the children who make rapid progress through the grade, shall be at least equal in number to those who make slow progress."

One of the important remedial measures in solving this great problem is not emphasized, namely: *better and more efficient methods of teaching, this is what North Bergen has relied on to produce its progressive betterments in age-grade conditions.*

Because "Retardation" means a below normal standard of attainment for pupils, and a higher standard of cost for communities, North Bergen, N. J. has, since 1907, given this problem special attention.

#### EDUCATIONAL WASTE

The factors used in reducing this educational waste of time and money, and waste in community progress, are:

1. Better methods of teaching.
2. Closer supervision of school work.
3. Better cooperation of parents.
4. Better school attendance.
5. More of the play spirit in class work.

(TABLE A)  
PERCENTAGE OF RETARDATION DIMINISHES

	1913	1916	1917	1918	1919
Under-Age	19	23	28	29	29
Retarded	27	19	16	13	13
	1920	1921	1922	1923	1924
Under-Age	29	30	30	30	29
Retarded	14	13	14	13	14

According to Dr. Ayres, the founder of the age-grade

According to Dr. Ayres, the founder of the age-grade method of measuring school progress, the table A, above, indicates a high standard of school attainment. Under-ageness of 19% in 1913 was gradually increased until in 1921 the table shows a 30% distribution. Retardation of 27% shown in 1913, is gradually further reduced and shows only 13% in 1918.

The excellence of these conditions is also seen from a comparison of North Bergen with other systems.

(TABLE B)  
COMPARATIVE DATA FOR 9 CITY SCHOOL SYSTEMS  
(American Ed. Digest, May, 1924)

City	Per cent Under-age	Per cent Normal	Total Under-age Plus Normal	Per cent Retarded
New York City...	14.0	46.0	(60.0)	40.0
Seattle, Wash. ....	10.3	47.6	(58.1)	41.9
Newark, N. J. ....	14.3	40.7	(55.0)	45.0
St. Paul, Minn. ....	6.7	45.9	(52.6)	47.4
Reading, Pa. ....	7.2	44.9	(52.1)	47.9
Grand Rapids, Mich. ....	9.0	43.0	(52.0)	48.0
Omaha, Neb. ....	8.0	37.0	(45.0)	58.0
Portland, Ore. ....	4.0	31.0	(35.0)	65.0
Birmingham, Ala. ....	1.3	19.0	(20.3)	79.7
North Bergen, N. J. ....	29.0	37.0	(66.0)	14.0

Nine cities are ranked in the order of highest efficiency as shown by the combined number of under-age and normal pupils (column 3).

Nine cities are ranked in the order of highest efficiency as shown by the combined number of under-age and normal pupils (column 3).

The excellence of these conditions is also found in the fact that Americans exploited the efficiency of German schools—exploited by Germans to American pedagogues visiting the German Empire and they in turn to American Educators. Their schools contained 50% of retardation but this was not revealed until statistics leaked out after the war.

### EYE-MIND EDUCATION

After working ten years upon the solution of the problem of Retardation, I found that we had about reached its maximum reduction for several reasons:

Teacher and pupil morale waned and effort accordingly, because:

1. Retardation problem was no longer a stimulation.
2. Because of the disorganization due to influenza epidemic.
3. Because of emphasis given to well known differences in pupils.
4. Because of emphasis given to intelligence testing.
5. Because of unsatisfactory salary conditions.

In the midst of these perplexities, salaries were raised and Eye-Mind Education was practiced for the purpose of maintaining the high standards we had attained. After careful analysis, observation, and personal tests, I became convinced of its great educational values. After seven years' experience with Eye-Mind Education, I class it as one of the marvelous discoveries of the present age, second only to that of radio waves and their control. The Bates' method of Educating the Eye-Mind, to prevent and remove eye and mental strains, to prevent and lessen Retardation in schools, is soundly established. Its contributions to the happiness of mankind is unspeakable.

Since 1920 our records of progress in Eye-Mind education have been carefully made.

*Not only does eye-mind education place no additional burden upon the teachers, but by improving the eyesight, health, disposition and mentality of their pupils, it surely lightens their labors and furnishes an additional means of preventing retardation.*

In 1924, out of 129 pupils wearing glasses, 18 were found with normal vision and 111 with vision below 20/20. Out of 4,026 pupils without glasses 1,133, or 28.1% had below-normal vision. The total below-normal vision was 1,244 out of 4,155 pupils or 29.9%.

In this year out of 118 below-normal pupils wearing glasses, 89 or 75.4% improved and of 1,072 pupils not wearing glasses but having below-normal vision, 693 have improved, or 64.5%. Out of a total of 1,190 pupils with below 20/20 vision, 782 improved, or 65.8%. Of those who improved 342 even attained normal vision, or 43.7%. This is indicative of what may be attained by this educative process under more systematic and persistent procedure.

Dr. William M. Carhart says in the Medical Times: "Not all retarded children are so retarded from eye strain, but the effects of eye strain are one of the main causes of such retardation."

The vision tests of 1925 showed that 17% of pupils with glasses had normal vision and 64% without glasses had normal vision. The year's work produced wonderful effects in Eye-Mind Education. The records show 70% of those wearing glasses were improved, that 87% of those not wearing glasses improved, and that of those improving, 56% attained normal vision.

### PERSONAL EXPERIENCE

The writer had 24 years' personal experience in wearing glasses, most of the time with bifocals. After this 24 years' knowledge of the advantages and disadvantages of glasses, they were laid aside on August 15, 1924, and have not been worn since.

Owing to attained age and 24 years of Eye and Mind strains being physically recorded, Eye-Mind improvement was slow but marvelous and my visual difficulties are now confined to poor print, poor type and poor light. I have attained wonderful improvement in this one and a half years of Eye-Mind practice. On many occasions truly miraculous conditions prevailed. They were periods of reflective, very free thinking, when thought flowed, was created as fast as pen could write. There was ease, relaxation of eye and mind. A noted experience of this occurred on the morning of November 3, 1925, after I had read some article upon school work. I was seeing thoughts with my mind's eye. Near and distant vision was wonderfully free and clear. These experiences and phenomena have occurred many times during the past six months. The thrill of ecstasy, and feeling of freedom during these periods, arising from

a complete emancipation from the thralldom of wearing glasses and their effects, are indescribable. They indicate an intimacy of relationship between the mind and matter never fathomed, and they also indicate that man is still a free agent to search out truth and happiness, and if he wills to use and uses his intelligence and available scientific data, he may carve out a new birth of freedom and progress for the human race. Man creates his own destiny.

Eye Education as an ally of mind development, of eye and physical health conditions and of human efficiency and happiness, should be practiced in every American school. Excepting radio, it is the miraculous wonder of the great age in which we live.

## Questions and Answers

Q—At intervals, sometimes months apart, I find my eyes twitching but it is hardly noticeable to an observer. What is the cause and how can I overcome it?

A—This is caused by mental tension which has a direct effect on the eye. Practice relaxation methods, palming and swinging.

Q—Why does eating ice cream hurt my eyes?

A—**Because the nerves of the eye are in direct relationship with the roof of the mouth**, and the sudden chill makes the nerves sensitive.

Q—If I am worried at night and lie awake, my eyes burn and pain, and I have a feeling that a magnet is drawing my eyes through my head. What causes this and what is the cure?

A—This is caused by the tension of the mind. Just before retiring and the first thing in the morning, practice the long swing.

Q—If I am sitting in the sun reading, I can see the print perfectly and my eyes do not trouble me, but if I raise my eyes and look at any other object, everything seems blurred and there are colored spots before my eyes. Is this caused by the sun or the manner in which I read?

A—The sun is beneficial to the eyes but the glare of light on the white page produces a tension of the nerves. The sun treatment should help you to become accustomed to the strong light. Sit in the sun with the eyes closed, allowing the sun's rays to shine directly upon the closed eyelids as you slowly move your head a short distance from side to side. Practice this daily for half an hour or longer.

## PRESBYOPIA NUMBER BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MAY, 1926

### Demonstrate

THAT the **long swing** not only improves the vision, but also relieves or cures pain, discomfort and fatigue.

Stand with the feet about one foot apart, facing squarely one side of the room. Lift the left heel a short distance from the floor while turning the shoulders, head, and eyes to the right, until the line of the shoulders is parallel with the wall. Now turn the body to the left after placing the left heel upon the floor and raising the right heel. Alternate looking from the right wall to the left wall, being careful to move the head and eyes with the movement of the shoulders. When practiced easily, continuously, without effort and without paying any attention to moving objects, one soon becomes conscious that the long swing relaxes the tension of the muscles and nerves.

Stationary objects move with varying degrees of rapidity. Objects located almost directly in front of you appear to move with express train speed and should be very much blurred. It is very important to make no attempt to see clearly objects which seem to be moving very rapidly.

The long swing seems to help patients who suffer from eyestrain during sleep. By practicing the long swing fifty times or more just before retiring and just after rising in the morning, eyestrain during sleep has been prevented or relieved. It is remarkable how quickly the long swing relieves or prevents pain. I know of no other procedure which can compare with it. The long swing has relieved the pain of facial neuralgia after operative measures had failed. Some patients who have suffered from continuous pain in various parts of the body have been relieved by the long swing, at first temporarily, but by repetition the relief has become more permanent. Hay fever, asthma, sea-sickness, palpitation of the heart, coughs, acute and chronic colds are all promptly cured by the long swing.

Read fine print with relaxation for clear close and distant vision.

## Presbyopia

By W. H. BATES, M.D.

**PRESBYOPIA**, or old age sight, occurs in people after the age of forty. Although the sight may be good for distant vision, it is always poor at a near point. While, in most cases, it occurs after middle age, there are exceptions in which it appears before the age of forty and even in young children.

## **Generally Accepted Cause**

The cause is said to be due to a hardening of the lens, and the belief is that with advancing years the ability to read at the near point becomes much less, because with increased hardening of the lens, accommodation is difficult or impossible. The lens, I believe, is not a factor in accommodation. In my book, "Perfect Sight Without Glasses," I have described the evidence which proves that the change in the focus of the eye is not brought about by a change in the form of the lens.

## **True Cause**

The true cause of presbyopia is a strain or an effort to see. When a person with presbyopia tries to read without glasses and fails, the patient feels that an effort or strain has been made. When this effort to see is increased, the vision, instead of being improved, becomes much worse. One can demonstrate that it is not possible to improve the ability to read fine print by any kind of an effort. When a patient with presbyopia rests the eyes by closing them, or by looking away from the page and then looking back at the reading matter, the vision is temporarily improved. Some people have been cured by resting their eyes at frequent intervals during the day without trying to see. After resting the eyes, the vision is usually momentarily improved. In other cases, it can be demonstrated that the patient is trying to concentrate. Let me suggest that the reader look at the upper left hand corner of a letter F, which is of sufficient size to be distinguished. Try to imagine a small area of this corner to be the blackest part of the F. Without shifting your eyes or closing them, keep on concentrating or trying to concentrate on this one point. Note that for a few seconds it is readily done, but very soon one feels a strain, and that to keep the eyes fixed on this one point becomes more and more difficult. The eyes feel uncomfortable and every once in a while the eyes shift and the upper left hand corner of the letter becomes blurred and is frequently lost altogether. The whole letter, in fact, becomes imperfect and blurred while trying to concentrate on the upper left hand corner. It is usually a relief to look away from the F and think of something else. It can be demonstrated that trying to concentrate on one point can only be accomplished for a short time. In other words, concentration for any length of time is impossible. This experiment is of great importance because persons suffering with presbyopia fail to read because they try to concentrate. Concentration may be all right on numerous occasions, but it is of no value in improving the sight. There are people who are able to help themselves when they find out what is wrong. Knowledge of the true cause suggests the cure. For this reason, some people have cured themselves of presbyopia by just resting their eyes without trying to concentrate.

## **Treatment**

When a patient with normal sight reads fine print, it can be demonstrated that while the letters are blacker and clearer, the white spaces between the lines appear whiter than they really are. If one looks at the letters, the eyes seem to become tired and the vision fails. If, on the other hand, one looks at the white spaces between the lines from one side of the page to the other, it is possible to imagine the white spaces much whiter than they really are without discomfort, fatigue, or loss of vision. Whenever one fails to read at the near point, the attention is not attracted to the white spaces between the lines, but an effort is being made to look directly at the letters. When one regards the white spaces, the whiteness may be improved by closing the eyes and remembering something else that is much whiter, such as white snow, white starch, whitewash. Now, when the eyes are open, the first glance at the white spaces enables one to imagine them whiter than before, but only for a short time, a second or a fraction of a second. Then close the eyes and remember the white as before. When the memory has become perfect with the eyes closed, again regard the white spaces with the eyes open, and note that there are times when the white spaces become intensely white. When the imagination of the white spaces improves, the imagination of the black letters also improves. By continuing to look at a white space, shifting from one side of the page to the other, after the imagination of the white space becomes more nearly perfect, the black letters are read correctly, easily, without any effort or fatigue.

When the black letters become clear: use central fixation - look directly at the letters to read them.

## **The Thin White Line**

When the imagination of the white spaces has improved, it often happens that one can see or imagine he sees a **thin white line** much whiter than the white spaces, a line which extends from one side of the page to the other, which is **located between the bottom of the letters and the upper part of the white space between the lines**. The consciousness of this thin, white line is a wonderful help. Most people are cured of presbyopia when they become able to imagine they see this white line. It is bright, clear, and distinct. It gives a restful, pleasant feeling in all the nerves of the body when the thin, white line is seen, remembered, or imagined. In cases of inflammation, when one is able to imagine the thin, white line, pain in the eyes, head or other parts of the body disappears as though by magic.

A thin white, glowing, bright line can also be seen along the outer edge of a white piece of paper.

## **Failures**

There are a number of causes of failures, and this number is oftentimes multiplied when different individuals become able by some ingenious method to bring about a failure. The most common cause of failure is to look at the black letters and to pay no attention to the white spaces between the lines. Regarding the black letters always lowers the vision and requires an effort, a strain which the patient can always realize. Sometimes, the white spaces may be improved sufficiently so that one begins to read the fine print, and almost immediately the vision is lost because of the great temptation to look at the letters.

Modern teachers state to look at the spaces, relax, imagine, see the spaces clear, then; look at/read the letters. If the eyes feel strain, return to the spaces or look to the distance. When the eyes are relaxed; read the letters again. Reading through the center

of the words also prevents strain, blur. When looking at the white spaces: shift on the space. Do not stare at it.

The thin, white line has been observed by many people who failed to read. In all cases, the white line was forgotten and an effort was made to read by looking at the letters. It seems to be a reaction of the human mind while using the eyes properly for people to at once stop using their eyes properly when their vision improves. They seem to think that they get a glimpse of good vision by the memory of the thin, white line, and all that they need is a start and that they can then get along without the thin, white line. It is the thin, white line that helps people to read and although I may get the habit of cautioning them about looking at the letters, and have them demonstrate immediately that looking at the letters is a bad thing, they find it exceedingly difficult to confine their attention to it. One elderly patient complained that she could see the white between the lines until the letters came out. The improvement in her sight was a distraction and prevented her from imagining the thin, white line. It required some weeks or longer before this patient was able to avoid the strain caused by an improvement in her vision.

When the vision flashes clear – keep shifting, blinking. Avoid freezing up with the body, eyes rigid, immobile in an attempt to hold onto the clarity.

Keep shifting, blinking, allow movement, relax.

Some patients keep their eyes open continuously without blinking. When resting the eyes by closing them, it is not always easy to help the patient to keep the eyes closed a sufficient length of time, or until one becomes able to remember a perfect white. When the memory is perfect, the eyes, mind, and all the nerves of the body are at rest. Rest of the eyes and mind increases their efficiency. When the eyes are open, and the white spaces between the lines are imagined, it is absolutely necessary that they be closed in about a second. Too many patients close their eyes for too short a time, and when they open them they are very apt to keep them open too long a time. It is really remarkable how difficult it is for some people to close their eyes for part of a minute and then to open them for just a second. They seem to forget everything they know as soon as they test their sight. Over and over again, I have had them prove that **testing the sight causes a strain which always lowers the vision**. Testing the imagination is different and is less apt to cause a strain. A patient with presbyopia can look up at the ceiling or a white cloud in the sky, and remember or imagine a mental picture of a perfect white color, and do it without any conscious strain or effort. Just as soon as they look at the fine print, they forget their imagination and fail by making an effort to see. One might suggest that in the cure of presbyopia, one should first find the principal cause of failure. It is necessary to be on the lookout for more than one cause. Some patients can produce many causes of failure in a short time. The ingenuity they exhibit is often times very remarkable.

After some of my tests, the patients ask questions or make statements which convince me that they pay no attention whatever to my directions for avoiding the strain. Many patients' minds seem to be bewildered by the numerous thoughts that they have about presbyopia, which have been told to them by other people. They have a bad habit of outlining their own plan of treatment, which they may practice unsuccessfully.

### **A Presbyopia Cure**

A patient over sixty years of age came to me recently wearing convex 3.50 D. S. in each eye for distant vision and convex 6.50 D. S. in each eye for reading. Although these glasses enabled him to read fine print, they caused him continuous pain, discomfort and fatigue. His eyes were so bad that looking at the Snellen test card even at a distance gave him pain. Without his glasses, his vision was about 10/40 in each eye.

By looking at the spaces between the lines of black type of the Snellen test card at ten feet or further, he felt no pain; but when he looked at the letters, he very soon was able to demonstrate a strain which blurred the letters, produced double vision and caused him much discomfort. By practicing for several hours, his vision improved until he became able to read the bottom line in flashes at one foot and the twenty line of the Snellen test card at ten feet.

When looking at the white area, spaces, there is nothing to see, so the person avoids effort, strain to see. The mind, eyes stay relaxed. When this relaxation, no effort is continued when looking at the letters, the letters are seen clear. When the vision is clear, the eyes can see the tiny details of the white paper, the small wood fibers the paper is composed of. Bring the paper close to the eyes and experience microscopic vision. Shift point to point on the tiny fibers. (Keep the edge of the paper away from the eye to avoid a paper cut to the eye.)

He was given a Snellen test card to hold in his hand at about one foot and was advised to regard the figure 2 in flashes, alternately closing his eyes and resting them. In about half an hour, he became able to flash the 2 at every trial. At first he could see it only for a fraction of a second, but finally became able to see it almost continuously for part of a minute. A card with fine print was fastened to the Snellen test card just below the figure 2 at about one foot from his eyes. By alternately seeing the figure 2 quite perfectly and flashing the fine print for about a second, he became able to see some of the words of the fine print without losing the figure 2.

There have been other patients who have been cured of presbyopia by similar methods.

### **Stories from the Clinic**

#### **NO. 75: PRESBYOPIA**

**By EMILY C. LIERMAN**

FOR some time I have been treating a woman, aged eighty, for presbyopia. She also has imperfect sight for distance which cannot be improved by glasses. This condition has been described by eye doctors as very difficult or impossible to cure. The retina, optic nerve, and all other parts of the eye, are seen to be normal when the ophthalmoscope is used. Recent observations have demonstrated that the cause is due to eyestrain. When the strain is relieved, the vision always improves and the sight may become normal.

Two years ago, when this patient's vision was first tested with the Snellen test card, she read 10/100 with the right eye and 10/70 with the left. She was unable to read fine print with either eye, at any distance. After resting her eyes during treatment, by just keeping them closed, she read 15/30, but some of the letters on the 30 line appeared double. Palming relieved the double vision.

Double vision is, of course, only an illusion and is caused by strain. The quickest cure for this is to cover the closed eyes with the palm of one hand, and only uncover the eyes to open them long enough to see one letter of the test card at a time. After doing this,

quickly close the eyes and cover them again with the palm of one hand. In this way, the patient does not keep the eyes open long enough to strain or produce double vision.

Later, this patient had a relapse and was discouraged to find that she could not read the test card so well. I soon learned that, although the patient had practiced many times a day, she had been making an effort to see better, and had made her sight worse. At a subsequent visit, she became able to read small print by rereading large familiar letters. Her vision for the test card also improved to 12/30 after closing her eyes for ten minutes or longer. This time she read the letters without seeing them double. From the beginning of her treatment up to the present time, her visits have been irregular and, because of this, it has taken her much longer to be cured.

When most patients grow older, they are very apt to strain more than when younger, and they are not conscious of the strain produced while reading, sewing, or seeing at a distance.

The sunlight helped this patient tremendously. Whenever possible she was placed in the sun, and the sunlight was focused on her closed eyelids with the sunglass. This always improved her vision. When there was no sun, I placed her close to a strong electric light for a half hour or longer. She liked this treatment because the sunlight was so restful to her, and she could read the test card at ten feet.

I have been treating another patient, a **man aged sixty-four, with presbyopia**. The vision of both his eyes was the same, namely 15/30. He could not read newspaper nor magazine type at all without glasses. When he looked down, he had double vision in the left eye.

Very little could be done for him in the beginning of the treatment, because he had a bad habit of unconsciously staring. He also made a great effort to concentrate while reading or while otherwise occupied. What a surprise it was to him, when he learned that when he tried to concentrate, his vision was lowered. This also produced a great deal of pain and discomfort in his eyes and head, causing a general depression for hours afterward.

I advised him to close his eyes in order to rest them, and to remember something he had seen perfectly. At first he could only remember his pain and discomfort, but by showing him the Snellen test card, illuminated by a strong light and held about one foot from his eyes, he became able to see or imagine the whiteness of some of the halos. Then, when he closed his eyes, he remembered the halo for a moment. By alternately looking at the halo, closing his eyes and remembering it, he became able to flash the halo or to see it for a few moments. By practice, the white halo was imagined more frequently until his memory became almost continuously perfect.

The pain was soon relieved. It was an easy matter to treat him after that. Blinking became a habit, and he learned to shift quickly and easily. I find that some patients stare even though they do blink often. They keep their eyes fixed in one direction or on one thing. In this way they do not get any relief and the vision does not improve. The normal eye shifts about a quarter of an inch or less while blinking, but it is not noticeable. People who wear glasses seldom shift their eyes. That is the reason why eye-glasses become tiresome to so many people.

At a recent visit, my patient became able to read 10/20 with the test card, and he was no longer troubled with double vision. Closing his eyes often to rest them helped. Now that his distant vision had improved so much, I was anxious to help him to read fine print or diamond type. During one of his previous treatments, I helped him to read newspaper and magazine type, which was an encouragement to him. When the fine print was placed about eight inches from his eyes, he asked: "You don't think I will ever be able to read such fine type as that, do you?" This question amused me, because most patients with presbyopia ask the same question. I answered: "Yes, I know you will."

With a great deal of doubt in his mind, he followed my advice. He was given a booklet, which contains microscopic print, and told to hold it about eight inches from his eyes. Then directly above this print was placed the small diamond type card, which describes the Seven Truths of Normal Sight. Then above this was placed another, a little larger in size, describing the fundamentals of treatment by W. H. Bates, M.D. This card is made up of different sized type, which starts rather large at the top and graduates down to fine reading type at the very bottom of the card. The patient was directed to look at the white spaces between the microscopic type; then blink and shift his eyes to the white spaces of the diamond type; then blink and shift again to the larger white spaces of the Fundamental card. In this way, my patient read sentence after sentence of the Fundamentals until he had read the very small print at the bottom of the card. The patient is grateful for learning how to use his eyes normally.

← HALO  
WHITE  
GLOW

Halo - White glow - The white paper closest to the edge of the black ink of a black letter appears whiter than other areas of the page, a bright, glowing, pure white. The glow also appears around colored letters, objects.

Fig. 3. The Eye As a Camera

The photographic apparatus: D, diaphragm made of circular overlapping plates of metal by means of which the opening through which the rays of light enter the chamber can be enlarged or contracted; L, lens; K, sensitive plate (the retina of the eye); A, B, object to be photographed; ab, image on the sensitive plate.

The eye: C, cornea where the rays of light undergo a first refraction; D, iris (the diaphragm of the camera); L, lens, where the light rays are again refracted; R, retina of the normal eye; A, B, object of vision; ab, image in the normal or emmetropic eye; a', b', image in the hypermetropic eye; a'', b'', image in the myopic eye. Note that in a' b' and a'' b'', the rays are spread out upon the retina instead of being brought to a focus as in ab, the result being the formation of a blurred image.

Fig. 4. Diagram of the Hypermetropic, Emmetropic and Myopic Eyeballs

H, hypermetropia; E, emmetropia; M, myopia; Ax, optic axis. Note that in hypermetropia and myopia the rays, instead of coming to a focus, form a round spot upon the retina.

Editor's Note: The little poem below by James Russell Lowell called "The Fountain" applies to the normal eye. The eye at rest is constantly moving just as the water in the fountain.

### The Fountain

Into the Sunshine,  
Full of the light,  
Leaping and flashing  
From morn till night;

Into the moonlight,  
Whiter than snow.  
Waving so flower-like  
When the winds blow;

Into the starlight  
Rushing in spray,  
Happy at midnight,  
Happy by day;

Ever in motion,  
Blithesome and cheery,  
Still climbing heavenward.  
Never weary;

Glad of all weathers,  
Still seeming best,  
Upward or downward,  
*Motion thy rest;*

Full of a nature  
Nothing can tame.  
Changed every moment,  
Ever the same;

Ceaseless aspiring,  
Ceaseless content,  
Darkness or sunshine  
Thy element;

Glorious fountain,  
Let my heart be  
Fresh, changeful, constant;  
Upward, like thee!

—JAMES RUSSELL LOWELL

This poem is written with the words placed in different areas of the page in order to get the eyes moving, shifting in a variety of directions.  
Move the head with the eyes.  
Shifting, movement = relaxation,  
clear vision.

### The Blind Man

WE are sure that many of our readers will be interested to read about Edith Collins. Edith is a pupil of Miss Elizabeth Hansen, a teacher in Chicago, who cures imperfect sight by Dr. Bates' method.

One day Edith and her little girl friend passed a blind beggar on the street and feeling very sorry for him, she stopped and talked with him. Edith had been treated and cured of imperfect sight by Miss Hansen, and had become very adept in applying the method herself, so she began teaching it to the old man. She and her little girl friend visited him twice each week in his hovel, and taught him to palm and use the sun treatment.

He was so ill that much of his time was spent in bed, but Edith told them to move his bed so that the sun would shine directly on his eyes. Little by little his sunken eyes came forward and he began to feel better. He followed the little girl's rules faithfully, even though a visiting nurse laughed and called the method "bunk." After three months, even the nurse must have changed her opinion, as the little girl rushed to Miss Hansen and told her that the old man was cured. She had met him on the street and he could see! He told little Edith he could read the headlines of the newspapers and smaller words in spots and that he was going out of town to look for work.

Miss Hansen wrote us about what Edith had accomplished, but to make it more authentic, we received the following misspelled

Two little girls that heard the blind man's story,  
Told him that they would teach him the Bates method  
to a blind man's eyes when they found him  
sitting under a bench.

They cure the blindness, his eyesight and  
health in a natural  
Treatment. Sunlight, looking, shifting  
and well doing on better a lot of optical chokes and  
different exercises, emerging, spiritual freedom.  
Children in a room the best Natural Vision  
improvement therapy.

We blind man cured, the new  
eyes, the newspaper, which  
the old man has seen, looks for  
a job and concludes his  
practice the Bates method

letter sent to Edith by the old man himself.

Dear edith:

i am in clear water florida i am traveling and you don't know how tickled it made me feel when i could see but when i reached my sister out here she nearly fainted when she saw me, and at first she wouldn't beleave that i could see so she took an apple and held it up to see if i really coud see now we are traveling and want to go California i hope you are well and thank you again and again for helping me.

i remain  
your patient who was once a blind man.

### Big and Little

This is a fact that is sad to tell;  
It's the empty head that is bound to swell;  
It's the light-weight fellow who soars to the skies.  
And burst like a bubble before your eyes.  
A big man is humbled by honest praise,  
And tries to think of all the ways  
To improve his work and do it well;—  
But a little man starts of himself to yell!

—Joseph Morris.

---

Reading is to the mind what exercise is to the body. As by the one, health is preserved, strengthened and invigorated; by the other, sight, imagination and mental efficiency are enormously improved.

---

Do a little good every day. Tell your friend to blink more often!

---

STARING: 1 Kings XIV-4,

"But Ahijah could not see; for his eyes were set."

### Effects of Presbyopia

By W. H. BATES, M.D.

PATIENTS who have been cured of presbyopia, which is caused by eyestrain, are able to do more satisfactory work than those who have imperfect sight and wear glasses. We receive many reports from patients who have had difficulties in their special line of work and have found that they accomplished more and were more accurate after their presbyopia was cured. Frequently, people of fifty years or more, lose their positions because of mistakes made in figures or whatever their work may be. They are not always told the reason for their dismissal. They are simply discharged and a younger man put in their place.

One of my patients, sixty-four years old, told me that, after having worked faithfully and steadily for forty years in one place, he had been informed that he could no longer figure accurately. It was a shock to him when he was placed on half pay and sent to another department. He was presbyopic, but was cured by treatment without glasses. During the absence of the younger man, he was temporarily placed in his former position. His work was so accurate and efficient that he was reinstated permanently.

Artists have the same experience with colors. It can be demonstrated that colors, when seen under a magnifying glass, become less distinct. White becomes a shade of gray; black becomes a lighter shade of black. It can also be shown that objects seen through glasses do not appear to be of the same size as the same objects viewed with the naked eye. Many artists are disappointed with their work because for some good reason they feel that it is not appreciated. The great mistake they make is that, like other people suffering from presbyopia, they believe that because their ability to read is improved with glasses, their perception of colors and form is also benefited. It is not always easy to convince artists that glasses actually lower their vision not only for colors, but also for form.

### Questions and Answers

Q—Why do animals' eyes shine, and why do they see better at night?

A—It is the reflection of the light from the front part of the eye which makes them shine. It is not known why some animals see better at night than they do in the daytime.

Q—Why do Albinos always have poor eyesight?

A—On account of the absence of pigment, Albinos' eyes are not protected from the light. However, they do not all have imperfect sight. It is because their mental equipment is imperfect that some have imperfect vision. When the memory or imagination is improved, the vision also improves.

Q—What color eyes are the strongest? I have been told that color matters, why?

A—The color of the eyes has no effect upon the strength.

Q—Doesn't it hurt to wear eye-glasses for near-work during the interval of eye practice?

A—You should use your eyes correctly all day long, no matter what you may be doing. Practice blinking, shifting, central fixation, and imagining stationary objects to be moving opposite to the movement of your head and eyes. Wearing glasses for any purpose whatever retards your progress and lowers your vision.

### Thumb, Finger Movement

Q—What is the movement of the thumb and forefinger, and how does it help?

A—Let the ball of the thumb rest on the ball of the forefinger. Move the thumb in a circle, about one-quarter of an inch in diameter. When the thumb is moving continuously, one can imagine that all the nerves of the body are moving with the thumb. This prevents the stare and strain. This movement of the thumb can be practiced when inside a room at home, office... or on the street. When the right foot moves forward let the thumb move in the same direction. Then, when the left foot moves forward, let the thumb move backward. Alternate.

Example;

Right foot forward > Thumb moves forward >

Left foot forward > Thumb moves backward <

Alternate:

Right foot forward > Thumb moves backward <

Left foot forward > Thumb moves forward >

Then, practice alternating with the left and right hands.

This exercise also activates a form of oppositional movement as the thumb moves forward and backward on the finger and as the thumb moves with and opposite to the movement of the feet. This exercise relaxes the mind, body, eyes, improves eye movement and activates and integrates the left and right brain hemispheres.

When practicing the long swing, the movement of the thumb is a help. When you turn your body to the right, move your thumb in the same direction. When you turn your body to the left, move your thumb to the left. Let the movement of the thumb be a continuous movement.

When you practice the short swing, the slow, short, easy, circular, continuous movement of your thumb in the same direction as the movement of your head and eyes, it helps you to see better, to remember better, and to imagine better.

See larger picture of thumb movement in November 1921 issue.

Q—I am forty-five years of age and have worn glasses for eighteen years. As my eyes have pained me for so long, is it too late to expect help or to discard my glasses?

A—It is certainly not too late to discard your glasses and improve your vision. When relaxation methods are employed, the pain disappears and the vision improves. I suggest that you palm for five minutes ten times daily, or more often if possible. Practice the sun treatment for one-half hour, one hour, or longer, every day that you have sunshine. The circular movement of the thumb, as described above, relieves pain almost immediately.

## CATARACT NUMMBER BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JUNE, 1926

### Demonstrate

1. Demonstrate that when the eyes are stationary, they are under a tremendous strain. Stand before the Snellen test card at a distance of fifteen or twenty feet. Look directly at one small area of a large letter, which can be seen clearly. Stare at that part of the letter without closing the eyes and without shifting the eyes to some other point. The vision becomes worse and the letter blurs. Stare continuously, and note that the longer you stare, the more difficult it is to keep the eyes focused on that one point or part of the letter. Not only does the stare become more difficult, but the eyes become tired; and by making a greater effort, the eyes pain, or a headache is produced. The stare can cause fatigue of the whole body when the effort is sufficiently strong and prolonged.

2. Demonstrate that when the eyes are moving from one point to another, frequently, easily and continuously, the stare, the strain, or the effort to see is prevented and the eyes feel rested. In fact, the eyes are not at rest except when they are moving. Note that when you look at a letter on the Snellen test card and alternately shift from the top to the bottom of it, the vision remains good or is improved. When the letter is seen perfectly, the eyes are shifting; and when seen imperfectly, the shifting stops.

3. Close your eyes and remember your signature. This can usually be done quite perfectly. Try to remember the first and the last letter of your name simultaneously. This is an impossible thing to do and requires a strain. If you shift from one letter to another, you can remember your signature, one letter at a time; but if you make an effort to remember it, the memory and the imagination of your signature disappears.

## Cataract

By W. H. BATES, M.D.

### Defined

**CATARACT** is an opacity of the lens of the eye. The lens of the eye is located in the pupil just behind the colored part of the eye, the iris. The lens is about the size of an ordinary pea. It is curved more on the front part than on the back. It is suspended in the eye by a bag-shaped structure, called the capsule. The capsule is a thin membrane. Covering the inside of the front part of the capsule is a layer of cells resembling in form and structure some of the layers of the skin of the body. The cells of the front part of the capsule are believed by some authorities to cause a secondary cataract after the lens has been extracted. Some years ago, I demonstrated by a long series of experiments that secondary cataract is not caused by these epithelial cells, but by scar tissue. The lens, itself, is composed of a number of layers of transparent tissue, which lie parallel to each other. When one places a number of sheets of plane window glass in a pile, with each pane of glass parallel to all the others, the pile of glass is transparent, but if one sheet or more is at an angle, that is, not parallel, the pile of sheet glass is clouded. This is a simple description of what takes place in the lens of the eye when it becomes opaque. When the lens is clear, its layers are parallel to each other. When the lens is opaque, one or more of the layers is at an angle to the rest. **Some patients with normal eyes are able by means of an effort to consciously produce a cataract.** When the cataract is beginning to show, it can be increased consciously by the memory of imperfect sight, which requires an effort with a resultant contraction of the muscles on the outside of the eyeball. When one group of eye muscles contract, the eyeball is lengthened and myopia is produced. When another group of muscles contract, the eyeball is shortened with a production of hypermetropia. When all the muscles of the eye contract sufficiently, the eyeball is squeezed in such a way as to change the parallelism of the layers of the lens with a consequent loss of its transparency.

### Occurrence

**SENILE CATARACT.** There are various kinds of cataracts. The most common form is called senile cataract, because it usually occurs in elderly people after the age of fifty. Exceptions, however, are found in which the cataract may occur at a much earlier period. In the senile cataract at the beginning of the cloudiness of the lens, one sees opacities extending in nearly straight lines from the periphery, or the outside margin of the lens, to the center. Later on, the parts of the lens between these lines of opacities become clouded until the whole lens becomes totally opaque. A lens is said to be ripe when its whole structure becomes opaque, when the patient's vision becomes so poor that he is unable to count his fingers held about a foot from the eyes.

**CONGENITAL CATARACT.** When a child is born with an opacity of the lens, such a cataract is called congenital.

**TRAUMATIC CATARACT.** A traumatic cataract is caused by some mechanical injury like a blow or the puncturing of the lens by a sharp object. Being struck by a baseball or having a sharp object, such as a stick or a toy, thrust in the eye, is a common cause of traumatic cataract.

**COMPLICATED CATARACT.** When in addition to cataract, the patient has some disease of the eye, glaucoma, atrophy of the optic nerve, or serious inflammation of the interior of the eyeball, he has what is called complicated cataract. In these cases, the patient is usually unable to distinguish light in some parts of the field.

There are other kinds of cataract which occur less frequently.

### Symptoms

Occasionally, a cataract may be sufficiently prominent to be recognized with the naked eye. In most cases, however, one cannot discover the cataract without the aid of the ophthalmoscope. When cataract is far advanced or the lens becomes totally opaque, the red reflex of the normal eye is not seen in the area of the pupil. If the cataract is only partially developed, one sees a red reflex shining through a clear part of the lens while other parts of the lens are more or less opaque.

### Demonstrations

Some years ago, when I was attending lectures at a medical college, an experiment was performed which was so convincing that I have always remembered the details. A professor was talking about the eye. He showed us an enucleated eyeball of a cow, and called our attention to the fact that when he held the eyeball loosely in his fingers, the pupil was perfectly black. Then, when he squeezed the eyeball, almost immediately the pupil of the cow's eye became distinctly white from the pressure exerted upon the lens. Then, when the lecturer relaxed the pressure of his fingers, the pupil at once became perfectly black as it was before, and the cataract disappeared. The experiment was repeated a number of times. The pressure on the eyeball always produced cataract; relaxation of the pressure was always followed by the disappearance of the cataract.

Some years ago, I performed an experiment on a rabbit which had just been killed by chloroform. By dragging upon the muscles on the outside of the eyeball, it was possible to obtain pressure on the lens and produce a temporary cataract. When pressure on the eyeball was released, the cataract disappeared. By advancing the muscles and fastening them permanently to the back part of the eyeball with the aid of sutures, the cataract which appeared in the pupil was permanent so long as the pressure was maintained by the advancement of the muscles. The facts demonstrated very conclusively that cataract in the rabbit's eye can be produced by pressure on the eyeball with the aid of the muscles on the outside of the globe.

## Treatment (Cures for Cataract)

If cataract can be produced in a rabbit's eye experimentally, one would expect the same thing to occur in the human eye. Treatment which relieves pressure on the eyeball is always beneficial. It is very interesting to discover that all cases of uncomplicated senile cataract have been benefited by relaxation or rest, at first temporarily, later more continuously or permanently.

There are a great many methods of treatment which bring about relaxation in the cure of cataract. The measures employed are not injurious. In fact, there is no possibility of making the condition of the eye worse. It is well to emphasize the fact that the same method of treatment to obtain relaxation is not a benefit in all cases. Patients need to be treated as individuals.

**1. REST.** Closing the eyes and resting them, or covering the closed eyelids with the palm of one or both hands, without exerting any pressure on the eyelids, has improved the majority of my patients. In my book, I report a case of **cataract which was cured permanently by palming for a long period of time, twenty hours continuously.** Palming for five minutes hourly is usually beneficial. With the eyes closed and covered, it is well that the patient allow his thoughts to drift from one thing to another without trying to remember one thing in particular all the time. By thinking of pleasant things, it is often possible for the patient to forget that he has eyes and in this way a larger amount of relaxation is attained.

**2. SWINGING.** Swinging is very helpful in the cure of cataract. This swinging of the body can be done with the patient standing or sitting. Some patients have practiced the swing while sitting in a chair for many hours during the day. When tired, they would alternate with palming. When the swinging is done correctly, it is restful and a benefit not only to cataract, but to other conditions of the eye. In swinging, one moves the body, head and eyes from side to side. When the body sways to the right, the head and eyes move in the same direction. When the body moves to the left, the head and eyes also move to the left. When the eyes move to the right, all objects not regarded are to the left of where the eyes are looking. When the eyes move to the left, all objects not regarded are to the right. By practicing the swinging exercise, many patients soon become able to imagine stationary objects to be moving in the opposite direction to the movement of the head and eyes. The great benefit derived from the sway is that the stare, the strain, and concentration are prevented. One cannot sway, move the eyes, and at the same time hold the eyes stationary in order to stare or concentrate.

The normal eye with normal sight never sees anything with perfect sight continuously, unless it can become able to imagine it to be moving. This movement is usually about one-quarter of an inch from side to side. Things imagined to be stationary soon become imperfect.

**3. MEMORY, IMAGINATION.** It is not possible to remember a letter of the Snellen test card perfectly unless it is seen perfectly. It is not possible to imagine a mental picture of the letter perfectly unless it is remembered perfectly. **Furthermore, it is not possible to see the letter perfectly unless one has a perfect imagination of a known letter or other object as well with the eyes open as with the eyes closed.** One of my patients had normal sight with the right eye, but only perception of light with the left eye which had a ripe cataract, or a cataract in which the whole lens was opaque. With the right eye, she could remember or imagine perfectly the letters that she was able to see perfectly. When she covered the good eye with a screen, she told me that she could imagine the small letter on the Snellen test card as perfectly with her left eye as she, could with her right. She was told that because of her poor sight in the left eye, she was unable to imagine perfectly at the same time with her left eye open. She remonstrated with me and was very positive that she could imagine as well with her left eye open as with her right. Finally, I asked her how much she could see on the strange card, and much to my surprise she read it with normal vision. When the eye was examined with the ophthalmoscope at the same time that she said her vision was normal, the cataract had disappeared. She was right and had demonstrated the truth that when her imagination was perfect, her sight was also perfect and in order to have perfect sight, it was necessary for the cataract to disappear, which it did. This case was one of the strongest evidences that imagination treatment is one of the best methods that can be employed to cure cataract. It interested me so much and emphasized the value of the imagination so greatly that it has become a routine treatment for my other cases. While it is beneficial in most cases, it is seldom curative because very few patients have so perfect an imagination.

When using one eye at a time - notice the memory, imagination is best when using the eye with the clearest vision. Using, improving the memory and imagination when working with the eye with less clear vision improves the clarity of vision in that eye. Improving the vision in that eye, both eyes, improves the memory and imagination.

I treated a woman, aged fifty-six for the first time on November 7, 1923. The right eye had incipient cataract with a vision of 15/70. The left eye had a ripe cataract with a vision of only perception of light. The numerous eye doctors, whom she consulted all advised an operation for the removal of the cataract of the left eye, and told her that no other treatment would be of any help. The

Palm and think of pleasant things, let the mind drift from one happy thought to another. Even when the mind stays on one subject it will move to different parts, objects, ideas... connected to the subject, then the mind may drift on to a new subject, then back to the original one with new ideas.

Long swing and see oppositional movement - 'the swing' - objects move in the opposite direction that the eyes, body move to.

Perfect memory, imagination of a object with the eyes closed and open - Shift on the object - Clear vision.

patient was benefited by palming, by swinging, and most of all by the use of her imagination. When her imagination, with the right eye open, improved, her vision improved to the normal. With her left eye open, her imagination was not so good, but even with an imperfect imagination her vision at once improved to 15/200. After two weeks of treatment, there were days in which her imagination became, with the left eye open, as good as with her right eye open, with normal vision in each eye. After some months of treatment without my supervision, the vision of the right eye became permanently normal and the cataract disappeared. By continuing the treatment at home, the left eye obtained normal vision for short periods of time only. Since she obtained normal vision with the left eye, although temporarily, it is possible for the temporary improvement to become permanent.

The memory of perfect sight is a rest to the eye, with a coincident relaxation of all tension or strain of the muscles of the eye.

**4. FINE PRINT.** Cataract patients become able to read fine print at six inches or nearer to their eyes more quickly than do patients with imperfect sight from other causes. By reading fine print frequently, or for long periods of time, the cataract becomes less.

People that have unclear close vision and wear stronger and stronger close vision eyeglasses develop increased eye muscle tension, abnormal eye shape, pressure, tension on/in the eye, blur at all distances, cataracts and other eye problems. Bifocals further increase the vision impairment and cataracts... Strong glasses for distant vision also causes this condition. Removing the glasses and improving the diet, avoiding drugs often reverses, removes the cataract.

Reading fine print often, close to the eyes, cures cataracts.

Sunning. Face the sun, eyes closed, move the head side to side. Relax, think happy thoughts.

**5. SUN TREATMENT.** The eyes need sunlight. People who work in mines, where there is no sun, sooner or later develop inflammations of the interior of the eyes. The cloudiness of the lens from cataract is lessened by exposing the eye to the direct rays of the sun. When using the sun treatment, it is best to let the eyes become accustomed to the sun by mild treatment at first. Have the patient sit in a chair with his eyes closed and his face turned toward the sun. He should slowly move his head a short distance from side to side. **The movement of the head prevents concentration of the sun's rays on one part of the eye.** After some days of treatment, or when the patient becomes more accustomed to the light, one may use the sun-glass with added benefit. Direct the patient to look far down and while he does this, lift the upper lid gently, exposing to view the sclera or white part of the eye. Now, with the aid of the sun-glass focus the sunlight on the forehead or on the cheek, and then rapidly pass the concentrated light over various parts of the sclera. This requires less than a minute of time. It is not well to be in a hurry. One should wait until the patient becomes sufficiently accustomed to the sun to permit the upper eyelid to be raised while he looks far down, **exposing the sclera only. It is important that the patient be cautioned not to look directly at the sun.**

## Prognosis

The cure of cataract is usually accomplished more quickly than the cure of some other diseases of the eye. My assistant, Emily C. Lierman, has had unusual success in treating cataract cases, as she adapts my methods to each individual case. In her book, "Stories from the Clinic," the treatment is described in detail.

## Stories from the Clinic

### NO. 76: CATARACT

By EMILY C. LIERMAN

MANY patients, after being cured of imperfect sight, go their way and we never see them again. However, many come back, even after a period of five years or more, to report, or to show their gratitude. If a patient is cured quickly, he is very apt to forget that he ever had eyestrain. Normal vision helps him to forget, and he is able to go on with things that interest him without tension or strain. There is nothing that affects the whole nervous system more than eye strain.

I have deep sympathy for patients suffering from cataract. Some of these have told me that, when they first discovered, or were told that they had acquired cataract, the shock was so great it sometimes made them very ill. I have often wished that I could broadcast to every human being troubled with cataract, that they need not worry about an operation, nor fear blindness.

While treating patients at the Harlem Hospital Clinic, Dr. Bates placed under my care many patients with cataract. Some of them were children who were born with it, while others acquired it from an injury of some sort. If they faithfully practiced the daily treatment for their particular case, they always improved. There were no exceptions, although in all cases where the patient did not practice enough, it took much longer for a cure. Adults were also cured quickly when the directions for home treatment were faithfully carried out. Age made no difference.

A colored mammy, who was a faithful servant of one of our private patients, came regularly, three days a week for many months, and was treated for cataract. I have described her case in my book, "Stories from the Clinic." In the beginning of her treatment, she could not see the letters of the test card at five feet. As she explained it in her dialect: "Do you know, ma'am, ah can see nothin', no ma'am, nothin' at all at dis distance!"

Long periods of palming, early in the morning and late in the afternoon, when her work was done, helped her sight. In the clinic she was taught to sway her body slightly from side to side and to blink all the time. The swaying helped her to see things about the room moving opposite to the movement of her body. **The blinking prevented the stare, which is usually the cause of cataract.** The quickest way to obtain a cure is by palming, and I advise my private patients to practice it for several hours or many times each day. It would be impractical, however, to advise a clinic patient to use the same method, because they cannot spare the time from their work, nor can the employer spare them. If such advice were given them, their answer would surely be: "This treatment is only for those who can afford the time." Dr. Bates often tells them that it takes less time to use their eyes correctly than it does to use them incorrectly.

Clinic patients, as well as private ones, are advised to relax all day long. Mammy was to see things moving all day by watching

her broom as she swept the floors; the washboard as she washed the clothes; the clothes-wringer as she turned the handle; and the dishes as she dried them and put them in the cupboard. We treated her many times, but occasionally she had a relapse. These were sad times for mammy, when she had tears in her eyes and a heavy heart. Frequently she would say: "Ma'am ah knows der is no hope for me. Ah has displeased de good Lord." A kind word or two always helped her, and I made sure that she received many of them.

As time went on, she obtained normal vision with the use of the test card, and became able to read very fine print and to thread a needle. We left the Harlem Hospital Clinic, never thinking that we would hear from her again. Six years had passed, and new patients were coming and going from our own clinic, when one day about three months ago, we received a letter from mammy. All through the letter were words of gratitude and praise for what we had done for her. **She is now seventy-eight years old, and can still read her newspaper and thread a needle.** She asked for permission to come to see us. She wanted the Doctor to look at her eyes to prove that her cataract had entirely disappeared. We, of course, were anxious to see her. When she came both of her eyes were examined and no sign of cataract was found in either eye. Her vision with various test cards was 10/10, and she read fine print without any difficulty, because she did as she was told. She was cured. It was not always easy for her as her work at times required good eyes. Her madam had patience with her for she, also, was under treatment. During mammy's last visit, she said: "Ah jest knowed dat ah was cured 'cause ah could see de crumbs on de carpet to brush up, an' ah could see de dust all ober de furniture an' ah cleans better. De sun is clear now an' not in de mist no mo'."

About a month ago, another patient came with a report of good vision. She is **over eighty years old**, and has a disposition just as cheery as she had when I first knew her, about eight or nine years ago. Perhaps our readers will remember an article I wrote about her. She is the patient who was employed in an orphanage. Her duties there were to see that all the buttons were sewed on the clothes of little ones at the Home. She said she was the only daisy in the country while she was there. From the very beginning she had infinite faith that Dr. Bates could cure her without an operation. During one of her early treatments, when she noticed a decided improvement in her sight while palming, she could not resist the temptation to peep through her fingers at me and say: "I'll fool them yet." I asked her what she meant and she answered: "Oh! The other doctors who want to operate on my eyes." Well, she kept her word. She fooled them and was entirely cured. She has never worn glasses since her first treatment and the only reason for her being cured is, that she practiced faithfully the methods of treatment that helped her most. When she looks at you, her young, blue eyes twinkle and she wears a smile that won't come off.

### A Radio Talk (Military and Aviation)

The following lecture was delivered at Station WMSG, Madison Square Garden, on Tuesday, May 18th, by W. H. Bates, M.D.

FOR a few minutes this evening, I wish to talk to you about your eyesight. So many people are troubled with their eyes that I feel that anything that is a benefit to them should be broadcasted. In the first place, it is an error to believe that perfect sight requires hard work or an effort. Perfect sight comes without an effort. This is very easily tested. All you have to do is to look at a small letter in a book or a newspaper and note that when seen perfectly, it is seen easily. If you do something that is wrong, by trying to see this letter better or making an effort to improve it, your vision fails. If the efforts are continued and you concentrate on just one point of the letter, the vision not only fails, but your eyes begin to feel uncomfortable. Pain and headaches often occur when the eyesight is imperfect. People who have perfect sight are usually more comfortable than people who have imperfect sight.

It is generally believed that the normal eye has perfect sight all the time. A scientific study of the facts has convinced me that this impression so generally believed and taken for granted is far from the truth. **After forty years' special study of the eye under different conditions, I am convinced that the normal eye has imperfect sight most of the time.** Age is no exception, young and old are equally affected. (Perfect vision is clearer than 20/20. A person with 20/5 vision considers 20/20 imperfect.)

There is but one cause of functional imperfect sight, and that is, a strain or effort to see. The strain may be an unconscious one or it may be conscious and manifest itself by pain, fatigue, or other discomforts.

Light has a very important effect on the vision of the normal eye. The vision of all persons is imperfect when the eyes are first exposed to the strong light of the sun or the strong artificial light, but people who are super-sensitive to the light of the sun, should not dodge it, but should gradually accustom the eyes to the sunlight.

Moving pictures usually produce temporary defective vision. Some people have complained that they always suffered with pain and had poor sight whenever they regarded the screen with its flickering light. I believe that some years ago, when photography was less perfect than it is now, the pictures produced a great deal of eyestrain, much greater than at the present time. I always advise my patients under treatment for the cure of defective vision, to go to the movies frequently and gradually become accustomed to the flickering light. After this is accomplished, no other lights seem to bother them.

Noise is a frequent cause of defective vision of the normal eye. All persons see imperfectly when they hear an unexpected loud sound. Familiar noises do not lower the vision usually, but unfamiliar, new, or strange noises always do, at least temporarily.

#### Military

Artists, bookkeepers, lawyers, physicians, writers, mechanics, and others found their mental ability or efficiency increased many times with the aid of eye training. Many recruits for the army and navy were found to have imperfect sight and were rejected, although their eyes were normal. Eye training improved their sight.

The **cadets at West Point** and the **midshipmen at Annapolis** have been well trained to obey orders, and any method that was employed to improve the sight of the soldiers and sailors was grasped and practiced with unusual intelligence. One great difficulty, if not the greatest difficulty in helping the sight of the soldiers and sailors, was that those who had inquiring minds wanted to know the whys and wherefores of everything. They were slow in obeying orders and were, on the whole, difficult to cure, but those who were benefited usually had no questions to ask, no arguments to offer. They were sure to be benefited; they were sure to do as they were told, and because they did as they were told without any discussion, they obtained normal vision as a general rule at the first visit. The soldiers and sailors who were treated successfully, improved at the very beginning and improved so rapidly that most of them were cured in about an hour of eye education. Those who were cured became able to cure others.

The most important method employed was to have the patient sit with his eyes closed and rest them for half an hour or longer. Then, when he first opened his eyes, the vision was usually improved temporarily. It had a good effect when the patient was taught that a stare, a strain, or trying to see always lowered the vision, and often produced pain, headache, fatigue; or other nervous troubles. The demonstration that staring lowered the vision, helped the patient to avoid the stare. When he knew what was wrong with him, it made it possible for him to practice in such a way as to avoid the stare.

Blinking was a great help. The normal eye blinks, or opens and closes, unconsciously very often. It has been demonstrated that blinking consciously gives one temporary improvement in the sight.

A young man came to me soon after war was declared, begging me to help him, if possible, so that he could enlist in the **marines**. He told me that he had tried to enlist a number of times, but he was always rejected because of his poor eyesight. In order to be accepted, it was necessary for him to have perfect sight in each eye without the use of glasses. He proved to be an apt pupil, and by using his eyes without effort or trying to see, his vision soon became normal. The next time he applied for enlisting, he was at once accepted, because he had perfect sight. He wrote me a letter while he was in France, in which he reported that he went on the rifle range and made a score of 251 out of a possible 300 points. He was the second highest qualified man in his company, and was awarded a sharpshooter's medal. His best ranges on record day were the 600 yard slow fire and the 200 and 300 rapid. On the 600 yard range, he made six bull's eyes and four four's. The bull's eye for the 600 yard range was twenty inches in diameter. He had not been in Brest, France very long before a call came for fifty men from each company who had high rifle range records to go at once for quick preparation to enter the lines as machine gunners. He was among those selected.

The **aviation branch of the army requires very good sight**. It is interesting to note that while aviators may have normal sight when they first enlist, in the course of a few weeks their vision will begin to fail. They complain that at irregular intervals they suffer from attacks of blindness. At first these attacks are not severe, but later on they become worse. During one of these attacks of blindness, the pilot will lose control and the machine will fall to the ground unless the aviator can recover his vision before it is too late. A number of aviators have told me that they did not know of one man whose sight was continuously normal. For this reason, the death rate among aviators has been so high.

During the war, an officer in this branch of the service had a long talk with me in which he described his personal experiences. He said that if he were not feeling very well or were more or less nervous, he would have an attack of temporary blindness, in which he would lose control of his machine for some seconds or part of a minute. He believed that if the attacks lasted much longer, he would not survive. I told him that the cause of these attacks of blindness was due to eyestrain. By having him practice in the office staring, straining, or trying to see, his vision was very soon lowered. By making still greater efforts, his vision became so poor that he was unable to distinguish ordinary objects and everything became black. **He was convinced that the stare, concentration, or an effort to see, when sufficiently strong, could cause an attack of blindness.** He also readily understood that to prevent these attacks of blindness, it was necessary for him to stop staring or trying to see. I advised him to look at his compass frequently and see it perfectly without straining his eyes. By consciously remembering a mental picture of the compass, his memory improved. With the improvement in his memory, there followed an improvement in his sight which not only became better, but improved continuously. The attacks of temporary blindness became less frequent until they disappeared altogether, but it was necessary for him to keep practicing and looking at his compass in order to prevent a relapse.

These facts have led me to the following conclusions:

- + **First: All persons with normal eyes and perfect sight do not have normal eyes and perfect sight continuously.**
- + **Second: The cause is always an effort or strain to see.**
- + **Third: That treatment by eye training is successful when distant, small, familiar letters are read a few moments at least every day, and**
- + **Fourth and last: The good results obtained, justify the use of this method in all schools, the army, navy, merchant marine, and on all railroads—in short, by everybody who desires or needs continuous perfect sight.**

If any of you are interested in the preservation of your eyesight for yourself, your family, or your children, I shall consider it a privilege to answer any question sent to me at this station.

Natural Eyesight Improvement Improves Marines target score on rifle range.

Army Pilot during the war learns to avoid staring, strain, effort to see. He shifts on his compass, remembers a clear mental picture of the compass and his vision remains clear.

**Shift, Palm, Daydream Pleasant Thoughts. Remember, Imagine objects clear, in color, motion. Listen to a Johnny Cash song and imagine, visualize the story, objects (Trains...) he is sings about.**

### **Another Radio Talk Through WMSG**

On June 8th, about 8 P. M. (see exact time in Radio section of Daily Newspapers), Emily C. Lierman, Dr. Bates' assistant, will give an interesting and instructive talk on Eye Education.

Your comments will be appreciated.

MYOPIA NUMBER  
**BETTER EYESIGHT**

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JULY, 1926

**Demonstrate**

**I.** That the smaller the object regarded, the easier it is to remember. One can, with time and trouble, become able to remember all the words of one page of a book. It is easier to remember one word than all the words of a page. It is still easier to remember one letter of a word better than all the letters. Regard a capital letter. Demonstrate that it is easier to see or remember the top of the letter best, and the bottom of it less clearly than to remember the top and bottom perfectly and simultaneously. Now look directly at the upper right hand corner and imagine one-fourth of the letter best. Then cover the remaining three-quarters of the letter with a piece of paper. It is possible to look directly at the exposed part of the letter and imagine half of it best. Cover the part that is not seen distinctly, and demonstrate that half of the exposed part of the letter can be seen or imagined best, while the rest of it is not seen so clearly. With the aid of the screen, an area as small as an ordinary period, may finally be imagined. Demonstrate that the imagination of a perfectly black small period, forming part of a small letter at fifteen feet, enables one to distinguish that letter.

**II.** That, with the eyes closed, a small black period can be imagined blacker than one three inches in diameter. If this fact cannot be readily demonstrated with the eyes closed:

**1.** Stand close to a wall of a room, three feet or less, and regard a small black spot on the wall six feet from the floor. Note that you cannot see a small black spot near the bottom of the wall at the same time.

**2.** Place your hand on the wall six feet from the floor, and note that you cannot see your hand clearly when you look at the bottom of the wall.

**Myopia**

By W. H. BATES, M.D.

**Definition**

**MYOPIA** has been called near-sightedness, because the vision is usually very good for objects which are seen at a near point, while very dim or blurred for objects at ten feet or farther. In myopia, the eyeball is elongated. The normal eye, when reading fine print, becomes elongated, or myopic, during the time that the eye is focused for reading.

**Acute myopia:** When myopia is acquired, it is called acute myopia in the early stages. When treated at this time, it is readily curable without glasses. The practice of prescribing glasses in these cases, leads to a permanent use of them.

**Progressive myopia:** In these cases, the myopia increases quite rapidly, and may be accompanied by much discomfort, pain, fatigue, and loss of vision. In advanced cases, many become unable to see as well with very strong glasses as they can without them.

**Complicated myopia:** Many authorities have stated that the myopic eye is usually a diseased eye. It may be complicated with cataract or other eye diseases, or it may not. The exceptions are so numerous, that it can usually be demonstrated that diseases of the eye have nothing whatever to do with the cause of uncomplicated myopia.

**Occurrence**

Myopia usually occurs at about twelve years of age. It is rarely congenital. Some become myopic at the age of four, fifteen, seventy, or any age, earlier or later. Some children with normal vision may go through life without becoming myopic. Risley, after a careful study of the eyes of school children, believed that myopia was only acquired by children with astigmatism or with hypermetropia (far-sightedness). At one time, statistics were quoted that children living in large cities had myopia to a greater extent than those who lived in the country. I believe statistics are uncertain, because one can generally obtain statistics which prove the contrary.

It is a popular belief that habitual use of the eyes for reading, sewing, or for any other use at a near point, promotes the increase of myopia. Simultaneous retinoscopy always demonstrates that near use of the eyes—even under a strain in a poor light—instead of producing myopia, always lessens it or corrects it altogether.

Myopia – Distant Blur = abnormally elongated eyeball. 

Clear distant vision = Eye shape is round. 

Reading, looking at close objects, close distance with relaxation = The eye lengthens, elongates slightly and is almost round. This brings the abnormally elongated eye closer to the normal round shape necessary for clear distant vision. When the eye then looks to the distance, if relaxation is maintained, the eye tends to change to the correct round shape for distance and avoids the incorrect elongated shape that causes distant blur.

Another theory, that individuals who use their eyes repeatedly for distant vision suffer less from myopia, has also been disproved by simultaneous retinoscopy. A strain to see at the distance always produces myopia. During the late war, it was unusual to find sailors or aviators with normal vision, or normal eyes without eye-strain. In order to obtain recruits for these branches of the service, because of the general prevalence of myopia, the standard of the requirements for admission had to be repeatedly lowered.

## Symptoms

Myopia is always accompanied by a strained look of the eyes, when regarding objects. Partly closing the eyelids, a form of squinting, is often observed in myopia. When the sight is imperfect, this practice may improve distant vision for a few seconds; but at a near point when the sight is good, about five inches from the face, squinting always lowers the vision, especially when one eye is covered. The habit of squinting at any distance lowers the vision at all distances.

## Cause

Staring can always be demonstrated to be the principal cause, if not the only cause of myopia. There are no exceptions. We may say: "It is a truth that the cause of myopia is the stare." Contributing causes are numerous. Any child with normal eyes and normal sight, will at once become temporarily myopic if you scold him severely. Teachers with normal sight and normal eyes are usually relaxed, and do not stare or strain. On the other hand, teachers who wear glasses for myopia, are under a strain. This strain is contagious, and children under their care are more apt to acquire myopia than those who are under the care of teachers with normal eyes and normal sight.

## Treatment

The cause suggests the cure. Since the stare or strain produces myopia, the cure would naturally be rest or relaxation. This is obtained by palming, swaying, and improving the memory and imagination.

**1. Palming** ; Close your eyes and rest them for at least half an hour. Some receive more relaxation by covering the closed eyelids with the palm of one or both hands thus excluding all light. By thinking of pleasant things, rest your mind as well as your eyes. Some mild cases have been cured, at first temporarily, and later more continuously by faithfully following this practice.

Palm and think about pleasant things. Shift on objects, see them clear, in color. Imagine seeing oppositional movement of objects as the eyes shift on the imaginary objects and as you imagine walking into the scene and moving about.

**2. Swaying** ; Stand with the feet about one foot apart, facing the Snellen test card at a distance of fifteen feet. Sway from side to side, while moving the head and eyes in the same direction. It is a benefit to the sight to alternately open and close the eyes while swaying slowly, easily, and continuously a short distance from side to side. It is a help to imagine the Snellen test card, or one or more letters on the card, to be moving opposite to the movement of the body, head, and eyes. If the card, or a letter of the card, does not appear to move, the vision soon becomes imperfect.

While swaying from side to side, and observing that one or more letters appear to move in the opposite direction, it is possible for one with normal vision to imagine that the letters are seen with central fixation. By this is meant, seeing best the point regarded, and other points not so clearly. With normal sight, the point regarded shifts constantly. The vision is always imperfect if the letters are not seen, one part best. When regarding the letter "C," notice that when you look at the top of it, you see that part best, and the rest not so clearly. Then, notice that when you look at the bottom of the letter, you see that part best, and the top not so clearly. This can be done with any object. When regarding a chair, notice that when you look at the back of it, you see the back more clearly than the rest of the chair. Then, when you look at the legs, they are seen more clearly than the back is seen.

When practiced properly, without effort, the sway enables one to imagine each of the smaller letters to be as black as the largest letter on the card. The white part of all letters is also imagined to be whiter than other parts of the test card, where there are no letters.

**3. Memory and Imagination:** Improving the memory and imagination, is one of the quickest methods of curing myopia. This can be done by practicing with two Snellen test cards. Place one on the wall of the room, and hold the other close enough to the eyes to enable you to read the smallest letters with good or perfect sight. Now, step back one inch from the card on the wall, and read one of the smallest letters on the card in your hand. Then quickly close your eyes for one second, and remember the letter as well as you have seen it. Open your eyes and flash the same letter on the wall-card. Quickly close your eyes, whether there is an improvement in the vision or not, in order to avoid the stare or strain. Alternate, until the imagination of a letter on the wall-card at seven inches, becomes equal to the vision of the same

Sway left and right facing the eye chart and see the chart move opposite the movement of the body. Practice with the eyes open, closed, open.

Shift on the letter C and see one part best, clearest at a time in the center of the visual field.

Look at the top; the top is in the center of the visual field and is clearest.

Look at the bottom. The bottom is now in the center of the visual field and is clearest.

Shift part to part (dot to dot) and see one part (dot) clearest at a time in the central field. The central field moves with the eyes, part to part on objects and from object to object.

Practice on a chair. Shift part to part on the chair and see one part clearest at a time in the center of the visual field.

**Two Identical Familiar Eye charts.** Distant chart onto a wall. Close chart at a clear distance. Shift on identical letters on the distant and close charts with the eyes open, closed, open and remember, imagine the letters perfectly clear. Read complete directions on the left.

**letter on the hand-card at six inches.** When this is accomplished, increase the distance to eight inches from the wall-card. When the known letter can be imagined on the wall-card at eight inches for a second or fees, in flashes, as well as it can be seen at six inches for a longer period of time, increase the distance to nine or ten inches. Continue to increase the distance by gradually stepping back, as long as you can flesh the known letter on the wall-card, as well as, you can see it at six inches on the hand-card. When your ability to imagine or flash a known letter fails at five feet or farther, it is usually best to move closer,—close enough to flash successfully without effort.

One patient with myopia of 7.00 D. S., vision 4/200, obtained more benefit from "flashing" than from any other method. In half an hour, she became able to flash the letters at fifteen feet, as well as she could see them at six inches. When this was accomplished, her myopia disappeared, and she read a strange card 'with normal vision at fifteen feet, almost as well as she could see it at six inches.

## Prevention

In order to prevent, as well as to cure myopia, it is necessary that you use your eyes correctly all day long.

- 1. Blink frequently, just as the normal eye does. Staring is a strain, and always lowers the vision.**
  - 2. Shift constantly from one point to another, seeing best the part you are looking at, and other parts not so clearly.**
  - 3. All day long, your head and eyes are moving. It is important that you notice stationary objects to be moving in the opposite direction to the movement of your head and eyes. When you walk around the room or on the street, notice that the floor or pavement appears to come toward you, while objects on either side of you, appear to move in the opposite direction to the movement of your body.**
  - 4. Practice daily with the Snellen test card for five minutes or longer.**
- Shifting, blinking, and imagining stationary objects to be moving, can be practiced at all times and in all places, . no matter what you may be doing.

## Stories from the Clinic

### No. 77: MYOPIA

By EMILY C. LIERMAN

MANY times I have been called upon to answer the question: "How do you treat or cure myopic cases?" This has been asked not only by laymen, but also by physicians. It is not an easy question to answer, because myopic cases vary in their response to treatment, and each requires an individual application of the method. Some patients with a high degree of myopia improve or recover in a reasonable length of time, while others with only a slight degree become despondent, because it takes so long to be cured. These patients fail, because they are unable to retrain from making an effort to see. Myopic cases are cured quickly when they do exactly as they are told, instead of straining their eyes by trying to see.

Progressive myopia is generally believed to be incurable, and to my knowledge there is no method of benefiting or curing it other than the bates method.

A man, seventy years of age, called on me recently to learn what he could about the method. He said that he had been myopic since birth. Several eye-specialists had told him that he could never be cured. Opticians had also told him the same thing. His eyeglasses were changed every two or three years, and each time he was given stronger ones. When he was examined with the ophthalmoscope, it was found that he had incipient cataract in both eyes, in addition to myopia. When I told him about the cataracts, he said that other doctors had also informed him of them. He asked if I could help him, when so many others had attempted to do so by fitting him with glasses, and had failed. I told him glasses were not necessary, and suggested that he try the Bates method. With much hesitation, he finally consented. He said that he would believe in the treatment if I could improve the vision of either eye, for the distance, in one visit. At ten feet from the test card, he could see only the two hundred line, or the letter "C," but he said even that looked very much blurred.

I taught him to palm, and while he was resting his eyes in this way, asked him if he could remember a favorite chair in his home, or the title of a book he had read. I reminded him of a sunset, and a white cloud in a blue sky. He visualized the mental pictures described, and nodded his head as I mentioned one thing and then another. I continued this method for half an hour, and then asked him to remove his hands from his eyes, but not to open them. I told him to stand with eyes closed, and sway his body a short distance from side to side, just as an elephant does. This made him smile, but he did as I told him. He was than directed to open his eyes, and to blink frequently as he swayed. While moving his body from left to right, he was able to flash the letters of the test card, and without stopping, he read 10/50 with both eyes.

His face expressed his pleasure, and his eyes twinkled as he remarked: "I'm coming back for more treatment and will prove to those, who gave me no hope, that I am cured!"

Another patient, a woman, thirty-five years of age, was cured of myopia in two months' time. Her vision of the test card was 5/40 in each eye. During her first treatment, she made very little progress, because she strained so hard to see beyond two feet from her eyes. Palming seemed to tire, instead of helping her. She frequently removed her hands from her eyes, although she still kept them closed. I decided to have her try swaying her body from side to side, first while sitting in a chair, and later while standing. To help her to sway rhythmically, I practiced with her, and reminded her to blink all the time. When she became able to imagine things about the room to be moving in a direction opposite to the movement of her body, I told her to Flash one letter of the test card at a time. When she saw things moving in an opposite direction about the room, her eyes remained open in a natural way. Just as soon as she glanced at the letters of the test card, she squeezed her eyes, practically closing them, and the muscles of her face became tense. When she was again seated in her chair and had closed her eyes, I placed three large test cards, all similar, at different distances from where she was seated. I placed the nearest about one foot away, the second three feet, and the third, five feet from her eyes. We again started the standing sway and, while blinking, she was directed to look at a letter on the card nearest her, then to flash the same letter on the next card, and to repeat this with the distant card. This method was successful, and she was overcome with joy as she flashed each letter in turn on the cards.

Eight weeks later, she read 10/10 on different test cards. The retinoscope showed no more eyestrain, and the patient has not had a relapse since.

**FAR**  
5 FT.

3 - Shift quickly on the C on the 5 ft. card. Repeat.

**MIDDLE**  
3 FT.

2 - Shift quickly on the C on the 3 ft. card.

**CLOSE**  
1 FT.

1 - Shift quickly on the C on the 1 ft. card.

Sway (rock the body) left and right, see oppositional movement, blink and 'Flash' (shift quickly, fraction of a second) on one letter at a time on the same letter on 3 identical eye charts placed at 3 different distances.

## The Great Delusion

**"Wearing Glasses to Strengthen the Eyes"**  
**A Billion Dollar Industry Based on an Error!**

**By DR. WENDELL A. DIEBOLD**

TENS of thousands make their living in a profession whose basis is founded on a misconception! Strong statements I grant you, yet the saddest part is that they are only too true.

Fitting of glasses to aid our vision on the theory that the lens of the eye is a factor in accommodation, is the present practice. It is true that glasses do enable some people to see better—for a time—just as any crutch may help a lame man to get about, but when his lameness is gone or his broken leg has mended, he can throw away his crutch. Not so with the crutches of the eye. The longer, in most cases at least, glasses are worn, the poorer becomes the vision and the stronger must the lens be. In other words, the eyesight gradually becomes less acute—its keenness diminishes.

If glasses really strengthened the eyes, why should stronger and stronger lenses, ever so often, be required? If the theory that we are born with defective organs of sight (a rare condition), were correct, there might be some justification for the enormous number of folks with glasses, but all errors of refraction are functional, therefore, curable by the proper methods.

The general teaching regarding the eye has been that it is more or less of a fixed organ. It is supposed that some are born with short eyes and therefore they are apt to have various degrees of far-sightedness, and astigmatism—while others are supposedly born with long eyeballs, and therefore they are doomed to short or near-sight, technically known as myopia.

### Helmholtz Lens Theory

Experiments, made over a hundred years ago by Helmholtz and others in photographing a candle light's reflection from the front of the lens, are supposed to have demonstrated that the curvature of the lens changes during accommodation. Helmholtz's conclusion from his experiments was that the lens contracted and expanded. This supposed contraction and expansion of the lens was thought to be the factor that enabled the eye to accommodate for the near and distant point in reading. I say, it seemed so to them, although Helmholtz was never entirely satisfied himself, but his followers "more loyal than the king," for over a hundred years have accepted what he considered as the probable cause of the fact without further question, or attempt to prove or disprove the idea. All our present practice has been and is based upon this theory. If the theory can be shown to be wrong, then the whole present practice of the eye glass fitting fraternity, based on that theory, will have been proven to be wrong. A correct practice cannot be founded on an incorrect or untrue premise.

Now, while the rank and file of the eye glass fraternity have blindly accepted the teaching handed down to them in their colleges and schools, there have been many experiences in their actual application that have not coincided with their theory. A classical example is the cases of people who have had their lenses removed through a cataract operation and still have been able to acquire the ability to accommodate without a lens. This could never have occurred if the lens were the factor of accommodation. Again, tens of thousands of cases of near-sight, far-sightedness and astigmatism have been corrected and normal vision secured. It is evident that these results could not have been secured if the error of refraction were a fixed thing—something people were supposed to have been born with, and not a functional condition as first maintained by Dr. W. H. Bates of New York City.

## Dr. Bates Experiments

Dr. Bates, as long ago as 1886, cured cases of myopia by a simple method based on a principle that he later demonstrated scientifically. He was one of the few who was not satisfied with the usual explanations and when he found that he could by some simple methods secure correction of "errors of refraction," he realized that the old theory must be wrong. What did he do? He tried to prove, by reenacting the same experiment that Helmholtz performed, that the lens accommodation theory was correct. He worked almost continuously for two years and every experiment made proved that the theory was wrong, due to a mistaken interpretation of certain facts. Then he had to prove his own theory, which is, that the extrinsic muscles that move the eyeball also control its shape. The oblique muscles in contracting elongate the eyeball, producing myopia, and the recti muscles in contracting shorten the eyeball and produce hypermetropia. He made many thousands of experiments on animals of all kinds. He found that by cutting the superior oblique muscle that the retinoscope would not show any focusing of the eye. When it was sewed together again, the eye focused normally as before. This proves that the tension of the extrinsic muscles determines the shape of the eye, therefore, its focusing. So, on this basis, **Dr. Bates says that the bad habit of staring and straining (and squinting) to see (and other conditions of mental and bodily strain), causes an undue tension on the extrinsic muscles, which does not allow the eyeball to accommodate through shortening or lengthening at will, as it should, and therefore give us perfect vision.** Now the proof of the pudding is in the eating; not only has Dr. Bates, for many years, corrected all kinds of defective vision in tens of thousand of cases, but many other physicians all over this country and England, by using his methods, are securing the correction of far-sight, short-sight, "old age sight," astigmatism, cross-eyes, and even cases of cataract and glaucoma.

Dr. Bates' work and researches are undoubtedly one of the greatest boons of this century that has come to suffering mankind. Generations unborn will do homage to him. He at last has made it possible for nearly everyone to regain normal sight. The practice of a few of his simple rules will positively prevent children from ever developing defective vision. From a lifetime of study and practice, he asserts with the conviction of one who knows whereof he speaks, that to put glasses on children is a crime. My own experience convinces me that children and young people can regain perfect vision if they have lost it, or maintain it if they are now blest with it. The results in at least seventy-five per cent of adult cases have been more than gratifying in that their vision has been restored to normal. Even the cases where restoration could be only partially accomplished, because of the great degree of degeneration that had taken place, have been much improved.

All cases can secure improvement by these methods. Most cases can secure good sight without glasses, and young people and children can secure perfect vision without glasses.

In the year 2009 there are different theories, facts concerning what causes/cures unclear vision, how accommodation (eye looking at close distances) occurs.

Dr Bates proved that the outer eye muscles can produce accommodation.

Dr. Bates experiments proved that outer eye muscle tension disrupts the shape, function of the eye, cornea, lens, eye muscle function, focus of light rays in the eye, circulation, pressure on/in the eye resulting in unclear vision at close and far distances, astigmatism, strabismus, cataracts, conical cornea, detached retina, glaucoma, macula degeneration and other eye problems.

Dr. Bates proved that relaxation of the eye muscles returns the eye, cornea, lens to normal shape, function, eye muscles to correct function, correct focus of light rays in the eye, normal eye pressure and circulation resulting in clear vision and removal, prevention of astigmatism, strabismus, cataracts, conical cornea, detached retina, glaucoma, macula degeneration and other eye problems. Tension is also removed from the optic nerve enabling it to return to normal health, function.

The old Helmholtz theory, (now being stated as fact by most modern ophthalmologists) states that the lens changes shape due to action of the ciliary muscle to produce accommodation. Some eye doctors state that both the lens and eye change shape, others theorize the lens moves forward and backward as in a camera to focus on close and distant objects.

The size of the pupil, (controlled by the iris muscles) also changes and affects clarity of vision when looking at different distances, in different levels of light. The pupil constricts, becomes smaller in low light and when looking at close distances.

Accommodation and pupil constriction occur together. The ciliary and iris muscles may function together.

Mood, thoughts, emotions, pain, drugs, alcohol, caffeine, aspartame sweetener, some herbs affect pupil size, function.

A negative mood, fear, worry, tension, drugs... can cause abnormal pupil size in light, dark and affect the clarity of vision and may affect accommodation, un-accommodation.

Since accommodation, un-accommodation occurs/functions with convergence, divergence, these functions can also be affected.

**The Bates method relaxes and activates correct function of all the eye muscles;** outer - oblique, recti, muscle for tears, blinking... and the inner eye muscles - ciliary, iris... - resulting in clear vision.

The state of the mind, emotions, brain function also effects vision. Tension, strain in the mind can cause unclear vision and other eye problems even when the muscles are working normally, relaxed and the eye shape is correct.

The Bates method also improves the clarity of vision, eye health by relaxing the mind, improving brain function, left and right brain hemispheres, memory, imagination...emotions, thoughts.

The old theory of accommodation states that because the lens becomes hard with age (40 and up) the ciliary muscle can no longer change the shape of the lens to produce accommodation for clear close vision.

Many people 40 years and older, senior citizens, persons that have had cataract surgery, full removal of the lens see clear at close and far distances. People that have experienced unclear close vision at any age; young, 40, older have improved their close vision to normal with the Bates Method. This occurs due to the outer eye muscles changing the shape of the eye or the lens never becoming hard or the lens becoming flexible again, or the ciliary muscle relaxing, being freed from tension, strain, dysfunction, improved diet, circulation to/in the eye, lens or all of these conditions.

The lens and cornea refract/bend, focus light rays entering the eye, onto the retina. **Cornea 80%, lens 20%.**

The cornea and lens also control the amount of sunlight entering the eyes, acting as natural protection from overexposure to sunlight.

The size of the lens continues to grow into old age. The cornea can rebuild/heal itself, repairing injury, ulcers, scars.

The Bates Method helps activate this natural healing.

## A Radio Talk on "Better Eyesight"

By EMILY C. LIERMAN

I BELIEVE that most people are interested in knowing how to prevent eyestrain. Strain is the cause of much discomfort, pain, and fatigue. I want to reach those who must use their eyes all day long, those who are employed in offices, factories, stores, shops, and, in fact, wherever good eyesight is required.

I would like to say a few words to the business man who really needs good sight for the work he does. If he can accomplish his work without the aid of eye-glasses, it is done with less fatigue and in less time than when glasses are worn. Reports which have been received from those who have been treated, verify this fact.

When glasses are worn, the eyes and the mind are not at rest. When the eyes and mind are under a strain, it is difficult to work efficiently. When the business man or woman is arranging a business deal, unless the mind and body are relaxed, mistakes are made which may mean a great loss.

Eyestrain is contagious. This is particularly obvious in the department stores. While waiting at a sales counter to be served, I have watched the person ahead of me, straining her eyes as she explained to the saleslady just what she wanted. Unconsciously, the saleslady feels the strain of the customer and, not realizing the cause, suffers throughout the rest of the day, unless she knows how to relax. The saleslady, in attempting to please, tries so hard that she often fails to make a sale, because of the tension of all the nerves in her body. She does not know that this is caused by eyestrain. In five minutes' time she can be relaxed if she knows what to do. If she will remember to blink her eyes frequently, just as the normal eye does, all day long, she will feel relaxed and rested. When she talks to a customer, she should shift her eyes from one part of the customer's face to the other remembering to blink as she shifts from one eye to the other, to the nose, from one cheek to the other, the chin, the mouth, and back to the forehead. In this way she feels no fatigue whatever. I am not thinking so much of her sales ability, as I am of the restful feeling she desires to have when her working hours are over.

This applies not only to those who work in department stores and shops, but also to office workers. The stenographer who has to listen sometimes for hours at a time, taking dictation from the nervous employer who perhaps finds it hard to be pleasant, also needs all the pleasure and recreation that she can get. While she is taking the dictation, she must be careful not to be affected by the strain in the sound of the voice dictating to her. If she is not careful, she will make mistakes or be in a much strained condition of mind and body, when she leaves the office. Her strain can be relieved by watching her pencil move as she writes, being sure to blink frequently. Her employer appreciates her efficiency much more when she is able to take dictation without tension or strain.

Most people **strain their eyes while they are asleep**. Indications of strain are swollen eyelids upon rising in the morning, a feeling of heaviness and of not having had enough sleep. Early morning headaches are usually caused by eyestrain during sleep. This strain can ordinarily be relieved or prevented by palming. By this, I mean to close the eyes and cover them with the palms of both hands in such a way as to exclude all light, without exerting any pressure on the closed eyelids. If this is practiced before retiring and immediately upon rising in the morning, the eyes become relaxed sometimes within a period of five minutes.

Avoid twisting the neck when sleeping. Do not sleep on the stomach. Sleeping on the back is best to remove all pressure on nerves, muscles, vertebrae, joints. Some people prefer to sleep on their side. If its not causing tension, its ok.

Have you ever noticed an elephant as he sways his body from side to side? Sometimes he is looking straight ahead of him, or he is watching his trunk, as he sways his body. It means everything to the comfort of the elephant to keep swaying from side to side. This gives him a feeling of rest and relaxation and prevents him from becoming discontented and ugly.

The lion and tiger in captivity are always pacing up and down their cages. They are contented knowing that sometime or other the keeper will satisfy their appetites. They keep moving all the time they are awake, because in this way they obtain rest and relaxation. As the animal receives rest and relaxation, so may the human being, by swaying from side to side without effort or strain.

The **long swing** is particularly beneficial in improving the vision, and invariably helps those who do not sleep well. Stand with the feet about one foot apart, facing squarely one side of the room. Lift the left heel a short distance from the floor, while turning the shoulders, head, and eyes to the right, until the line of the shoulders is parallel with the wall. Now, turn the body to the left, after placing the left heel upon the floor and raising the right heel. Alternate looking from the right wall to the left wall, being careful to move the head and eyes with the movement of the shoulders. When practiced easily, continuously, without effort and without paying any attention to moving objects, one soon becomes conscious that the long swing relaxes the tension of the muscles and nerves.

(in the body and eyes.)

Stationary objects move with varying degrees of rapidity. Objects located almost directly in front of you appear to move with express train speed and should be very much blurred. It is very important to make no attempt to see clearly objects which seem to be moving very rapidly. By practicing the long swing fifty times or more just before retiring and immediately after rising in the morning, eyestrain during sleep has been prevented or relieved.

I would like to encourage the tired mother who stands on her feet most of the day, performing duties of the household which are seemingly endless. It is not always the small baby that tires her most; but the strain and tension caused by her concern for the comfort of her husband and other members of the family. Her desire to attend to all of her duties sometimes causes a great deal of eyestrain. This is more noticeable to her when she is called upon to thread a needle or to sew. Before she tries to thread a needle, she should close her eyes and rest them for just a second or two, holding the needle in place so that when she opens her eyes, she

may see the eye of the needle. By blinking, she will soon become able to thread the needle without her glasses. She should remember, while attending to other duties in the household, to blink her eyes and sway her body slightly from side to side. She can do this all day long, no matter what she may be doing, whether cooking or sweeping the floor, washing dishes, or anything else, and she will feel relaxed and happy.

It is a wise mother who keeps a rocking chair handy to rock her baby to sleep. The swaying back and forth gives rest to the baby and peace of mind to the mother. If she has children who attend school, she can easily teach them to relax by palming and swaying for a very short time before school. The mother can remind her child to blink the eyes often and not to stare at the blackboard or at the teacher. The child will soon notice that his vision becomes better.

For the benefit of those who desire to improve their eyesight and to work without the aid of eyeglasses, I shall be glad to answer any question addressed to me at this station, WMSG.

### WMCA Radio Talks

Perhaps it may interest our readers and their friends to know that each day, between four and four-thirty P. M., a short book-review on the works of Dr. Bates and Mrs. Lierman will be broadcasted from the Hotel McAlpin Station, WMCA. Any criticisms or suggestions will be appreciated.

### SCHOOL NUMBER BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

AUGUST, 1926

### Demonstrate

That vision is always imagination, either perfect or imperfect. What we see is only what we think or imagine we see. The white center of the letter "O", when seen perfectly, appears to be whiter than it really is, or whiter than the rest of the card. That part of the center of the "O" which is in contact with the black appears to be the whitest part of the white center. By covering the black part of the "O" with a screen, which has an opening in the center, the whiteness of the center of the "O" appears to be the same shade of white as the rest of the card. Now, remove the screen, and at the first glance, the center of the "O" appears for a short time to be much whiter than it really is. In other words, one sees something which is not really seen, but only imagined. When some people enter a room which is totally dark, they often imagine that they see a white ghost. They don't really see it; they only imagine it, but their imagination may be so vivid that no amount of argument will convince them that they did not see the ghost.

When one looks at the upper right hand corner of a large letter of the Snellen test card, it is possible to see that point best, and all the rest of the letter not so black. The part seen best appears blacker than it really is. The part seen worse appears less black than it really is. Things seen more perfectly than they really are, are not seen, but imagined. Things seen less perfectly than they really are, are not seen imperfectly, but are imagined imperfectly.

### School Children

By W. H. BATES, M.D.

MOST children have normal eyes when they enter school. In a few years, their sight may become imperfect. Acute cases are usually benefited or cured by prompt treatment without glasses.

### CAUSES

I have frequently called attention to the fact that in all cases of imperfect sight, **STARING** is present, and can usually be demonstrated. It is the cause of imperfect sight. When treatment corrects the habit of staring or trying to see with an effort, the vision becomes normal.

The surroundings have an important effect upon the vision. It is possible to lower the vision of any child by an unexpected noise or by punishment, either physical or mental. The vision is usually affected by the temperament of the people with whom the child comes in contact. When a child is comfortable, the sight is good. When a child is nervous, the vision is lowered.

The following case illustrates these facts. One-half hour after birth, a child was observed to squeeze its eyelids, wrinkle up its forehead and, in fact contract the muscles of its whole body. The child's eyes were examined with the retinoscope, and when it was straining so terribly, it had a high degree of near-sightedness. A drop of strong atropine solution was put into both eyes. Atropine is supposed to lessen the eyestrain which causes myopia. This child, however, was not benefited in the slightest,—the pupil dilated, but the near-sightedness continued. The remarkable fact was repeatedly observed that in spite of the atropine, the child produced at about fifteen minute intervals, or more often, all the errors of refraction known, for which glasses are prescribed. Sometimes it was far-sight in both eyes; sometimes far-sight in one eye and near-sight in the other. Astigmatism would come and go, and the degree, as well as the axis, was variable within short periods of time. Sometimes the retinoscope demonstrated that the eye had mixed astigmatism, that is, it was flatter than normal in one meridian, while the one at right angles to it was more convex than in the normal eye.

The nurse, who was not a graduate of any hospital, took the child in her arms, and began to rock it from side to side. Watching the child's face, one could see the muscles begin to relax, the wrinkles become less, the contraction of the muscles of the arms, limbs, and of the whole body, become relaxed. The little one opened its eyes and smiled; at this moment both eyes were normal.

Then it turned its face to the nurse's breast and promptly went to sleep.

The child was examined daily for about a week, then less frequently, about twice a week for several months, and then only occasionally. When she was four years of age, her eyes were normal. She was sent to kindergarten, and after being there for about a month, the retinoscope showed that she had myopia in both eyes, which strong atropine drops did not correct. I asked the teacher to encourage this child to dance and run as much as possible while at school. After two weeks, the child was examined again with the retinoscope and the eyes were found to be normal, with no myopia nor astigmatism whatever. At this time, the eyes were straight. A month later, the child was again examined. The right eye was normal, but the left eye was very far-sighted and turned in toward the nose. With the right eye open, the child could distinguish her parents, relatives, and some of her playmates across the street, at a distance of more than fifty feet. With the right eye covered and looking with the left eye, she could not recognize her acquaintances further off than fifteen feet. It was very evident that the sight of the left eye was imperfect.

Not long afterwards, I visited the kindergarten and was much shocked to find that the child was wearing glasses for the correction of the squint. It annoyed me so much that I at once called on the parents, and had a heart to heart talk with them. The father was a friend of mine and teased me a little for taking the matter so seriously. The mother remembered how much time I had spent on the child previously, and was willing to have me treat the child. The child's glasses were removed permanently and she practiced shifting, swinging, and palming. Reading a Snellen test card (the card with "E's" pointing in different directions) for about five minutes each day, was a benefit. In a short time, the eyes became straight and the vision of both eyes became normal at the same time.

Later, the child had a relapse which was evidently caused by being annoyed by a girl who had joined the kindergarten class during the previous month. It so happened that the child who annoyed the patient went away for a visit, and while she was gone, the patient's eyes became straight and remained straight. When the irritating child returned to the school, the patient again had a relapse. I recommended that the patient be taken out of the kindergarten and kept in agreeable surroundings with children and others who did not make her nervous. The child outgrew this nervousness and ten years later there had been no return of the squint.

## TREATMENT

**AGE**—One of the first questions that people ask is "How old should a child be before it can be treated?" The answer is that the younger the child, the more successful is the treatment.

**FREQUENCY**—Another question frequently asked is "How long does the child have to be treated before good results are obtained?" My habit is to ask the parents to wait and see the results of the first treatment. I am then usually able to tell them that the child has a temporary cure and does not necessarily need to come to see me again. If the child is only partially cured, however, it may be advisable to have him come for a few days, a week or longer, until he becomes able to improve his sight without my supervision. Then he may continue to practice at home until cured. If the cure is delayed, it may be necessary to take more treatments under my personal supervision.

**PALMING**—When palming, the patient closes the eyes and covers them with the palm of one or both hands, (Modern = both hands—see picture last page this book) in such a way as to avoid pressure on the eyelids. Babies, three years old or younger, have been taught to palm. When they find that the discomfort in their eyes or head is relieved by the mother covering their closed eyelids with the palms of her hands, the children may acquire the habit of doing it themselves. I have had cases of whooping cough, in which children three years old have stopped the cough by palming, after they had obtained benefit from palming done for them by an older person.

While nursing her baby, whose sight was imperfect and eyes inflamed, one mother was observed to cover its eyes with her hand. She said that the palming relieved the pain in the eyes, improved the sight, quieted the child, and promoted sleep.

**SWINGING**—One of the best methods for preventing staring is to practice the swing. We often see babies laugh or scream with delight when someone swings them sideways or up and down. They open their eyes wider, breathe more deeply, and the muscles of their arms, limbs, and whole bodies relax with pleasure and happiness. It is not conceivable that a baby so happy could have pain, poor sight, or be cross-eyed. Children and babies are forced to wear large tortoise-shell rimmed glasses, which invariably kills the joy in their hearts. They seldom smile, the eyelids contract, wrinkles appear on their faces, and the world becomes a place in which to be sad. Let us bring back the rocking chair, the swing, the cradle, and encourage mothers to swing their babies in their arms as they love and pet them.

**REST**—Children of all ages are benefited by resting their eyes and minds for a few minutes, several times a day. Teachers realize the benefit of rest in the school-room, and books are laid aside, windows opened, and a few exercises with deep breathing, are practiced. I am not aware that the school authorities have ever been criticized for devoting this daily amount of time to rest.

A more effective method for obtaining relaxation of the mind is as follows: A **Snellen test card** is permanently placed on the wall in front of the children, where it can be read by all of them from their seats. Twice each day or more often, the children read the card with each eye separately as well as they can. When practiced properly, reading the Snellen test card with both eyes open, or alternately with each eye, the other being covered, has improved the vision in all cases. In some cases, the vision became normal in two weeks or less, while other required a longer time to obtain this result. Practically all of the children were temporarily cured in three months.

It rests the eyes to read the Snellen test card with good vision. To fail to read it perfectly, requires a strain or an effort. When these facts are demonstrated and the child realizes the cause of its imperfect sight, much good may follow. When children do not know the cause, they have more trouble in obtaining relief.

Read a Familiar Eyechart twice+ per day with:

Both eyes together, one eye at a time, both eyes together again.

Use all correct vision habits: shifting, central fixation, blinking, shifting on a letter and remembering, imagining it clear, moving (the swing) with the eyes open, closed, open. Practice with the chart at a variety of close, middle, far distances. Practice with 3 identical eyecharts placed at 3 different distances in the sunlight.

### The Swing

Swing the child around by the hands clockwise, counter-clockwise, clockwise. Child looks up into parents eyes and also sees oppositional movement of objects in the visual field moving by in the opposite direction the body is spinning toward. Improves clarity of vision, gets the eyes relaxed, moving normal, straightens crossed, wandering eyes, activates, integrates left and right brain hemispheres, relaxes body, mind, eyes in a active, dynamic, fun state of mind.

**Rocking Chair.**  
See oppositional movement; Rock up - objects move down. Rock down - objects move up. Rock under a tree, sunlight shifting through the branches for saccadic sunning/eye movement. Daydream and sleep.

**Tree swing.**  
See oppositional movement when swinging. Occasional lean the body back and forward when swinging.

**Rocking Cradle** for baby. Good for the developing eyes, brain, body. Keeps baby feeling relaxed, safe and secure.

All forms of 'The Swing' gets the eyes shifting, moving, produces appearance of oppositional movement, keeps the body, muscles, joints mobile, active, relaxed, improves blood, lymph, energy flow, relaxes and soothes the mind, body, eyes, and keeps the eyesight clear.

Movement is natural, healthy!

Different types of The Swing are:

The Long Swing, Rock/Sway, Eye Shifting, Swinging a child by the hands, or in your arms, Rocking a child in your arms, Rocking Chair, Rope Swing, Cradle, See Saw, Merry Go Round, Dancing...

## Stories from the Clinic

### No. 78: SCHOOL CHILDREN

By EMILY C. LIERMAN

DURING the last year, I have had more **squint** cases under treatment than any previous year. My records show that all of these cases also had imperfect sight. All, with the exception of two little boys who were in the second and third grade, were too young to attend school. At the close of the Clinic in June, it was not necessary to send them to kindergarten, as every one of them was ready for the first grade.

I am very sure that parents who have children with squint or cross-eyes went to know what to do to correct the trouble.

Many of them, who visited us, were unwilling to have their girls or boys operated upon for the cure of squint. If the patients are faithful in the daily practice, we can assure them of a cure. In some cases where the sight of one eye is imperfect, while that of the other eye is normal, we advise a black patch to be worn over the good eye, especially during practice. This is done only when the eye with imperfect sight turns in or out.

It is always encouraging to the patient if he can see the eyes improve, or become straight, while under treatment. If I notice a decided improvement while treating such a case, I place my patient before a large mirror, and direct him to closely follow my instructions. I then quickly draw his attention to his eyes, and before he has a chance to strain, he notices the improvement. This usually encourages them to continue their practice until they have a permanent cure. Other patients who are not troubled with squint but have imperfect sight, are treated in a different way.

When children are too young to read the alphabet or figures, we use a test card with the letter "E" pointing in various directions. This card is placed at five or ten feet from the patient, and he is requested to tell in which way the letters are pointing. When the letters become smaller, they begin to look blurred. Then it is best to advise palming for five minutes or even less. When the patient again reads the test card, the vision is usually improved for one or more lines of letters. The child is then shown how to sway by standing and gently moving the whole body with the head from side to side. Most patients must be reminded to blink, so the child is frequently encouraged to blink, while swaying, just flashing the card and seeing one letter at a time. When children understand the great benefit derived from the sway of the body, there is no difficulty in curing their imperfect sight or squint. Most of the patients have some kind of music at home, and children as well as adults, enjoy keeping time with it, as they practice the sway which helps the patient to relax. Relaxation being the only way to improve the sight, the patient is thus benefited by the sway.

I am always able to teach my tiny tots their letters and figures by playing a game with each one. If he has squint, I place the card close to the eyes and point to the largest letter, and ask what it is. He may say, "I don't know," and then I mention whatever the letter is. After this, he is directed to play peek-a-boo, which means to look quickly, repeat the letter after me, and then close the eyes. This is exactly the same method used for adults, only it is not a game of peek-a-boo. When a child is instructed in this way, the second treatment becomes more interesting, and each time he is taught a few more letters.

I never forget to praise my little patients after each treatment, as it makes them more anxious to help me when treating them. The little fundamental cards play an important part in the treatment and cure. They help grown-ups, as well as children.

Mothers may at first find it a task to devote the necessary time and care to their children with imperfect sight, but the result is worth the effort. Children can practice the sway at home for five minutes before they go to school. When they read letters or words written on the blackboard, their vision always improves, providing they do not stare at the letters. Blinking frequently, while looking slightly below the line of letters they are reading, relieves all tension and strain. When no effort is made, children can read from their books, feeling relaxed and rested, both in mind and body. Boys and girls from the high schools, who have been treated and cured, appreciate this fact. Many school children whose defective vision has been cured, have interested their teachers in the matter. As a result, they came to Dr. Bates for treatment and were also cured. Dr. Bates and I realize the strain under which teachers of the Public Schools work. Many of them do not know how to relax, and their anxiety to instill knowledge in the minds of the children, keeps them constantly tense.

A young man who was just about to enter Columbia College, recently told me that every morning for one whole year after he was cured, he never missed an hour's practice with his eyes. He said it helped him to keep relaxed during school hours, and that he noticed that his mind was benefited. He could think easier and his memory, which was very poor while he was wearing eyeglasses, was so much improved that he found no difficulty in studying his mathematics and history. More boys than girls seem anxious to cure their imperfect sight. I believe this is because boys and young men are interested in more strenuous sports. Eyeglasses are useless to the oarsmen, football and baseball players and, for the sake of these sports, they are willing to practice faithfully to bring about a cure.

Eye patch helps improve the vision and movement of a crossed/wandering eye, gets the eye moving correct.

Alternate a palming and reading the test card. Sway, blink, flash (shift, fraction of a second) on one letter at a time. Relax.

Sway left and right. Relax, blink.

Long Sway. Sway and turn left and right. See oppositional movement.

## What the Bates Method Did for One School Boy

By MAY SECOR

Special Teacher of Speech Improvement, New York City  
Public Schools and Pupil of Dr. Bates

JOHN was **cross-eyed**; the taunts of his schoolmates kept him well aware of this. When he looked at an object directly in front of him, the pupil of his "lazy eye" was only partly visible; with this eye he could see the large "C" of the Snellen chart, only when he was within sixteen inches of the chart. John was nearly seven years old; he was retarded at school, having been obliged to repeat Grade 1A. He was a neurotic child,—extremely erratic in his behavior at school and at home.

During the latter part of his second term in 1A we began to instruct him in Dr. Bates' method of Eye Education. We aimed to keep John relaxed and happy; to present each exercise as a game; to suggest each game in such a way that he would be anxious "to try it"; to foresee an outburst of passion when it was brewing, and ward it off; in general, we aimed to instruct John in methods of relaxation, keeping him busy with happy, healthful thoughts and activities, thus avoiding correction and possible outbursts of passion. We admit that the case was difficult, and required much time and study. We used the following methods:

**1. INSTRUCTION TO PARENTS AND TEACHERS:** Teach the child's parents and teachers the principles underlying the Bates Method, and gain their sympathy and co-operation.

**2. REST PERIODS:** Enjoy two rest periods each day,—after lunch and after school or work. Go to your bedroom, open the window, remove your shoes and other tight clothing, and lie down and sleep.

**3. BLINKING:** Notice how gently and often a tiny baby blinks. Close your eyes and remember a baby blinking, and gently blink as a baby does. Blink as you read an eye chart or a book, play cards and other games, watch automobiles pass, or enjoy physical exercises.

**4. SWAYING:** Watch the moving pendulum of a large clock. Close your eyes and remember the pendulum moving. Gently sway as the pendulum does, and see things moving in the opposite direction, as you blink. Vary your position. Stand with your feet slightly apart as you sway your body. Sit in a comfortable chair and sway. Sit in a comfortable chair and gently sway the head from side to side.

**5. SWINGING:** Enjoy the long swing, the memory swing, and the variable swing fully described on the fundamental cards. As you shift, see letters and objects swing.

**6. PALMING:** Lie down or sit in a comfortable chair, and rest your feet and legs on a stool, which is as high as the seat of your chair, and tuck a pillow under each elbow. Gently close your eyes; cup your hands, and place them gently over your eyes, and enjoy the following: See something which is very black (a black cat, a black overcoat, or black velvet). Practice the memory swing as you make believe that you are swaying, reading the chart, looking at a certain picture, watching automobiles pass or playing a game.

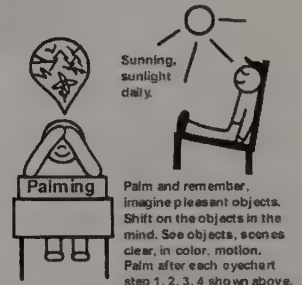

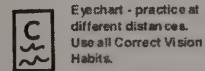

**7. READING TEST CARDS:** Stand and sway, or sit in a comfortable chair, and rest your legs and feet on a stool which is as high as the seat of your chair. Read the Snellen card lazily, comfortably, and gently blink as you read. Read the test card with your better eye and then palm. Read the test card with your worse eye and then palm. Read the test card with both eyes together and then palm. Practice with the pot-hooks chart as follows: Name or indicate with the hand the direction in which the letter points. Copy the chart, using white paper and black crayon. Read it with the "lazy eye" (eye pad on other eye). Copy a line at a time with black Kindergarten splints which have been cut in corresponding lengths.

**8. MEMORY:** While you palm, practice the memory swing. Recall the face of a friend, a certain picture, the odor of a rose, or the tune of some song you like.

**9. IMAGINATION:** While you palm, imagine you are taking a trip to the country or that you are drawing a small picture of a house or a dog.

**10. SUN TREATMENT:** Learn how to sway and blink with relaxation before using the sun treatment. Enjoy the sunshine; walk, play, or lie in it. Stand or sit in the sunshine, and gently blink, sway, and see things moving. Enjoy the long swing.

**11. READING BOOKS:** Read any book which is "easy for you to read" with fairly small print. Sit in a comfortable chair with legs and feet on a stool, and gently blink and read. Occasionally palm for a few minutes. Let the mind drift and visualize some episode in the story. Comic books, adventure, mystery, interesting stories.

Reading Comic Books improves the clarity of vision by activating many correct vision habits, natural eye functions;

+Relaxation, positive thoughts; as the person reads the interesting, entertaining story.

+Memory and imagination; as the person looks at the pictures and also visualizes his own pictures, remembers/imagines the story, things the pictures, story describe.

+Color treatment; as the person looks at the variety of colored pictures.

+Shifting; the eyes move in a variety of directions as the eyes shift from picture to picture and from one 'bubble' of printed words to another.

I know of three children that have improved their vision to clear, close and distant, by reading comic books in the sunlight and at night, in dim light under a blanket with a flashlight.

Their mind, body, eyes are perfectly relaxed when reading the comics = the mind, eyes do not strain = the vision is clear.

Remember when you were a child and would sit in your favorite chair and go off into a fantasy world reading your favorite comic book collection. My Favorite Comic book hero is Dr. Strange. Reading his stories of 'Ghost Flying' - Traveling in his Sprit, Astral Energy Body to combat evil in the Universe!

The mind, eyes can experience strain when being pressured to hurry, memorize quickly when reading school lessons, worrying about getting good grades... and when reading boring, uninteresting subjects at school, work.

The comics and other interesting stories, with pictures keeps the mind entertained, positive, relaxed in a deep and/or active 'dynamic' state, and this prevents strain, blur. It is easy to remember a story, picture you enjoy.

Dr. Bates cured unclear vision by getting the patient to think about, fantasize, remember, imagine pleasant, happy things, subjects the person enjoys.

**12. LEARNING NEW EXERCISES:** Begin by learning how to relax, blink, and sway, and then very gradually add other exercises.

**13. USE OF EYE PAD:** Wear an eye pad (patch) over the better eye at first for one-half hour, and then gradually increase the length of time.

**14. ENVIRONMENT:** Enjoy your lesson at patient's home, indoors or on porch, at instructor's studio, on a pier (if fond of boats), or in a park. **Select cheerful, pleasant people as companions.**

**15. SLEEP:** Before retiring: sway, blink, palm, and read the chart. Open bedroom windows, and if possible, retire at eight thirty, and remain in bed until six thirty or seven A. M. If wakeful during the night, palm and practice the memory swing.

In this way, we applied Dr. Bates' method of Eye Education to John's case. We treated John for seven weeks. He then spent two months in the country without treatment. Upon his return, we again took up the work.

The muscular control in the crossed eye improved from the second lesson on. The vision improved greatly, and the crossed eye gained the ability to fixate. But this was not all. In the fall, John's mother reported that he was "made over." At home John was pleasant and obedient; and whereas he had formerly been retarded at school, his record is as follows since he has been under our care:—

June 1925—Promoted to 1B

Oct. 1925—Advanced to 2A

Feb. 1926—Promoted to 2B

John has been re-educated—from the standpoint of vision, of nervous make-up, of behavior, and of intelligence. Since Dr. Bates' method has accomplished this for John, may we not apply it with equal success to other cases?

Dr. Bates will resume his lectures to patients, at 383 Madison Avenue beginning the first week of September. Invitations will be issued to patients.

### Announcement

Our readers may be interested to know that of November first, Miss S. I. Paisley, formerly of Washington, D. C., will be in Los Angeles as a representative of Dr. Bates.

Other representatives who have just completed Dr. Bates' Course on the "Cure of Imperfect Sight Treatment Without Glasses" are:

DR. J. B. CLAVERIE,  
1467 East 53rd Street,  
CHICAGO, ILLINOIS,  
and

DR ST. GEORGE FECHTIG,  
97 Madison Avenue,  
NEW YORK CITY,  
and  
PALM HARBOR,  
Pinellas County, Florida.

### HE WON'T STAY DOWN

This old world is sometimes jealous of the chap  
who means to rise;  
It sneers at what he's doing or it bats him 'twixt  
the eyes;  
It trips him when he's careless, and it makes his way  
so hard  
What's left of him is sinew, not a walking tub of  
lard;  
But it's only wasting effort, for by George, the guy  
keeps on  
When his hopes have crumbled round him and  
you'd think his faith was gone,  
Till the world at last knocks under and it passes him  
a crown:  
Once, twice, thrice it has upset him,  
but  
he  
won't  
stay  
down.

What cares he when out he's flattened by the cruel  
blow it deals?  
He has rubber in his shoulders and a mainspring  
in his heels.  
Let the world uncork its buffets till he's bruised from  
toe to crown;  
Let it thump him, bump him, dump him, but he  
won't stay down.

Sinew = solid resilient strength

My opinion of this poem is: That it describes Dr. Bates lifelong struggle against the optical industry. Dr. Bates determination to keep Natural Vision Improvement available to the public. To cure eye problems without eyeglasses, surgery, drugs.

## Questions and Answers

Q—My sight is good, but I am suffering from eyestrain caused by muscle imbalance. No oculist has been able to help me. I have had to become a cook from being a typist and dressmaker. If I focus my eyes on my fingers for more than a moment, terrific pain shoots through my eyes. I cannot stand light and have to cover the kitchen tables with a dark cloth. Please tell me what to do. Is it possible for me to discard the dark glasses I wear?

A—It is evident that when you look at your fingers for more than a minute, you stare, strain, and make an effort to see. Practice the variable swing. Hold the forefinger of one hand six inches from the right eye and about the same distance to the right. Look straight ahead and move the head a short distance from side to side. The finger appears to move, and the stare is prevented.

In order to overcome your sensitiveness to light, I suggest that you obtain as much sun treatment as possible. Sit in the sun with your eyes closed, and the sun shining directly on the closed eyelids. Slowly move your head from side to side in order to avoid discomfort from the heat. This should be practiced for half an hour or longer daily, whenever possible. When your eyes become more accustomed to the strong light, the sun should be focused on the closed eyelids by moving the sun-glass rapidly from side to side above the eyelids. Later this can be done with the eyes open as you look far down, exposing the white part of the eye by lifting the upper eyelids. (Directions for use of the sun-glass can be obtained from the Central Fixation Publishing Company).

The sun is focused and moved on the white part of the eye, not the pupil or iris.

Q—Often, when I am trying to see a thing, it will come to me, but my eyes will commence to smart, and then I blink and lose it. What shall I do to overcome that?

A—Blinking can be done correctly, and it can be done incorrectly. You strain while you blink. The normal eye blinks easily and frequently. Strain is always accompanied by the stare. By standing and swaying from side to side so that your whole body, head and eyes move together, the stare is lessened. The swing and the movement of the eyes lessens the tendency to stare.

Q—What does "seeing things moving all day long" mean?

A—Your head and eyes are moving all day long. Notice that stationary objects appear to move in the opposite direction to the movement of your head and eyes. When you walk around the room or on the street, observe that the floor or pavement appears to come toward you, while objects on either side of you, appear to move in the opposite direction to the movement of your body.

Q—My trouble is cataract. Shall I cover up the good eye while practicing?

A—Practice with both eyes together until your vision is normal. Then, cover the good eye and improve the vision of the poor one.

Q—Could cataract be caused by diseased teeth?

A—While it is possible for abscesses of the teeth to cause cataract, most cases are caused by eyestrain, and are curable.

## REST NUMBER BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

SEPTEMBER, 1926

### Demonstrate

#### 1. That the sway improves the vision because it prevents the stare.

Stand with the feet about one foot apart, facing a Snellen test card about fifteen feet away. Sway the body from side to side, at first with a rapid, wide swing. When the body, head and eyes sway to the right, observe that the Snellen test card is to the left of where you are looking. Then sway the body, head and eyes to the left. The test card is now to the right of where you are looking. Practice this sway for a few minutes and, without looking at the Snellen test card directly, observe that the whiteness of the card becomes whiter and the black spots on the card become a darker shade of black. The test card appears to move in the direction opposite to the movement of the eyes, while objects beyond the card may move in the same direction as the eyes move.

2. That when the forefinger of one hand is held about six inches in front and to one side of the face, the finger appears to move from side to side in the direction opposite to the movement of the head and eyes. (Move the head side to side, left and right.) Close the eyes and let the hand rest in the lap and remember the swing of the finger. Imagine that the hand, which is fastened to the finger, moves with it. Realize that when the hand moves, the wrist, the arm, the elbow and other parts of the body, being joined together, all move with the finger. Now try to imagine the elbow is stationary, while the finger is moving. It is impossible to do this. When the finger moves, you can imagine not only your body, but also the chair on which you are sitting, the floor on which the chair rests, the walls of the room, the whole building with its foundation, in fact, the universe to be moving with the finger. This is called the universal swing and is possible only when the memory, imagination, or the sight is good.

15 Ft.

Sway left and right in front of the Test Card. See it move opposite the movement of the body.

Variable Swing - finger to side of face. Move the head side to side and see the finger move in the opposite direction.

Variable Swing - finger in front of face. Move the head side to side and see the finger move in the opposite direction. Practice seeing this in the imagination with the eyes closed.

### Rest

By W. H. BATES, M.D.

REST and relaxation of the eye and mind is perfect when the vision is perfect, and can always be demonstrated.

When the eye is at rest, it is always moving. To demonstrate this, instruct the patient to close his eyes and imagine that he is looking fast over his right shoulder, then over his left shoulder. By alternating quite vigorously, the eyeballs can be seen to move from side to side. While the eyes are still closed, one can place the fingers on the closed eyelids and feel this movement. Now instruct the patient to imagine a shorter movement of the eyes from side to side, that is, look a shorter distance from right to left while the eyes are closed. The movement can usually be felt, but it is not so manifest to the observer as it is when the wide movement of the eyes is made. However, after a little practice, five minutes or more, when the patient is imagining the eyes are moving, one can feel the movement even though it may be very short, one-quarter of an inch or less. If the patient stares at a part of an imaginary letter with the eyes closed, the memory or the imagination of the letter becomes blurred and the movement of the eyeball is not continuous. On the other hand, if the patient remembers a letter perfectly, and shifts on it in the mind, the eyeball appears to move continuously a short distance in various directions.

When central fixation is practiced, that is, when one remembers or imagines one part of a letter best, the eyeballs move. If one tries to remember or imagine a letter, all parts equally well, the movement of the eyeballs cannot be seen or felt, and the eyeballs appear stationary. One can demonstrate the movement of the eyeballs very well with the aid of the ophthalmoscope. When the optic nerve is regarded with this instrument, one can always see the movement of the pigment of the eye or of the blood vessels of the retina when the sight, memory, or imagination is normal. This movement is slow, short, easy and continuous. When the sight, memory, or imagination is imperfect, the eyeball may move very irregularly, with frequent periods when it is stationary.

Eye immobility, impaired shifting = unclear vision.

In **nystagmus**, the eyeballs move from side to side, usually continuously, a distance so great that it is conspicuous. The rapidity of this movement may vary. It is always stopped after closing the eyes and resting them a sufficient length of time, several minutes or longer, or by practicing the slow, short, easy swing.

Nystagmus is generally believed to be difficult to cure. In fact, it is so difficult that very few cases have ever been reported as benefited by orthodox methods of treatment. It has usually been considered an incurable symptom of disease of the eye. Nystagmus is, however, to a greater or less degree, under the control of the mind of the patient. Some people are able to stop the movement at will. These cases, however, are rare. Some

From Dr. Bates Better Eyesight Magazine.

Eyes closed. Imagine looking over the left and right shoulders. First do this without moving the head. Then, imagine looking left and right and move the head with the eyes. Move relaxed, easy - look left, then right, left, right... no hurry. Notice the eyes move under the closed eyelids when imagining looking left and right. The brain, memory, imagination, left and right hemispheres... control eye movement. This activity relaxes the eyes, eye muscles, brain, head, neck, activates easy eye movement/shifting and activates, integrates the left and right brain hemispheres.

Eyes closed - imagine looking back and forth over the left and right shoulders and lightly touch the fingers onto the upper closed eyelids and feel the eyes move left and right.

Next - imagine shifting left and right on a small letter and feel the eyes movement become smaller, shorter. The eyes, eye muscles and brain, mental pictures work together.

children acquire the ability to practice nystagmus just as they learn to look cross-eyed. Nystagmus requires a strain. When practiced either consciously or unconsciously, the vision is always lowered. When the nystagmic movements are lessened or stopped altogether, the vision improves and has frequently become normal, either temporarily or permanently.

Some years ago I treated a boy, aged ten, for the cure of nystagmus. His mother told me that she had visited many physicians and had sacrificed a great deal financially in order to obtain a cure for her son. I tested his vision and found it normal at times, when the nystagmus would stop. Repeated tests demonstrated the fact that his vision was always worse when he had the nystagmus. While he was reading with almost normal vision, I said to him: "Stop the movement of your eyes!" Much to my surprise, he did what I told him and then read the card with normal vision. Then I said to him: "Start it up again and read the card." This he did very promptly, but he was unable to obtain normal sight. Again I asked him to stop the nystagmus and his vision became normal and remained normal as long as he had no nystagmus.

The mother paid close attention to the conversation. She realized that the boy was able to produce or stop the nystagmus at will. He seemed to be pleased by the attention he received when he showed off his control of it. The mother asked me no questions. There was no need of questions after the convincing demonstration that the boy gave of his ability to control the movement. There was a grim determination in her face when she left the office, and she grasped the arm of her boy with a great deal more force than was perhaps necessary. She spoke to the boy with considerable emphasis: "Just you wait until I get you home!" I am sorry that I cannot report what happened later, but I can guess. I hope that she was able to stop this bad habit without much severity.

It can be demonstrated that when the eyes are not at rest, the vision is always imperfect. When the memory or imagination is perfect with the eyes closed, the vision is improved when the eyes are opened. Usually the improvement of the vision is only temporary, and may last for only a second, or in flashes. In these cases, the memory soon becomes imperfect with the eyes open. By alternating perfect memory with the eyes closed, the memory with the eyes open usually improves. By practice, many patients become able to remember or imagine with their eyes open a small area of black or white, as well as they can imagine it with their eyes closed. When such patients look at a blank wall, where there is nothing in particular to see, no effort may be made to see and the vision improves. One can practice with the Snellen test card and remember for a moment one known letter of the card, with the eyes open, as well as one can for a longer time with the eyes closed. When one letter of the Snellen test card is improved, all the letters and other objects are also improved. The perfect memory of a known letter with the eyes closed is perfect rest, while an imperfect memory or imagination with the eyes closed or open is always a strain. It is a great help to many people with imperfect sight to demonstrate that rest improves the vision, while the stare or strain always lowers it.

To fail to see requires an effort. When the patient regards the letters which are so blurred and indistinct that he cannot tell what they are, he is always straining, trying to see, either consciously or unconsciously. People are cured of their imperfect sight when they cease to strain, stare, or make an effort to see. When I explained this to one of my patients, she said that I was wrong, that the only way she could see was by means of an effort. I had her test the facts. When she looked at the Snellen test card at ten feet, she could not read it with normal vision. At five feet her vision was better, but when she made an effort, her vision became much worse. The same was true when she regarded letters at a nearer point, three feet, two feet, or even one foot. An effort to see always made her sight worse. She had to demonstrate the facts repeatedly before she was finally convinced that her vision was good only when her eyes were at rest and no effort was made.

### Blinking

Blinking, when practiced properly, promotes relaxation or rest. The normal eye blinks continuously all day long when the patient is awake. **At night, when the patient is asleep, a movement of the eyeballs can be seen which resembles the movement of the eyeballs when the eye blinks.** When the eye blinks slowly and the upper eyelid is slowly closed, distant objects appear to move up. When the eyelids slowly open, objects appear to move down. This movement is usually accompanied by an improvement in the vision. Blinking is absolutely necessary in order to obtain continuous normal vision. The normal eye blinks unconsciously, easily, sometimes with great rapidity and at other times rather slowly. It is impossible to stop the blinking of the normal eye. Any effort to do so is a strain, which lowers the vision and, if kept up for some minutes or longer, produces pain, fatigue, dizziness, and other nervous symptoms.

The normal eye is shifting or looking from one point to another continuously, not only when one is awake, but also when one is asleep. **This continuous movement of the eyes brings about a condition of perfect rest.** To stare at one point for a few seconds or part of a minute is a difficult or painful thing to do. It requires a great effort which lowers the vision. It is not possible to see two black periods perfectly black at the same time. The only way that they can be seen perfectly black is to shift from one to the other alternately. It is not possible to see a large letter or a small letter perfectly without shifting or looking from one part of the letter to another part. It is well to realize that the human mind is not made to see more than one thing perfectly at a time. To see two or more things perfectly at the same time is impossible, but one can shift from one thing to another and alternately see each perfectly for a short time.

When regarding a person's face, it is impossible to see the whole face perfectly at once. It is necessary to shift from one part of the face to another to see those parts perfectly. If the shifting is more or less rapid, one gets the impression of seeing the whole of the face at once, when, as a matter of fact, only a small area is seen at a time.

Fig. 33. Demonstrating That the Back of the Lens Does Not Change During Accommodation

Fig. 4. The Usual Method of Using the Retinoscope. The observer is at one end of the subject that the latter is stable nervous, and this changes the refraction.

Shift left and right from one period to the other. One period at a time is seen clear in the center of the visual field. When looking at a period: shift on it: tiny part to tiny part to see it clear. Blink.

One of my patients had normal sight in one eye and one-half normal vision in the other. He was very positive that he could see every letter of the Snellen test card perfectly at the same time. He was not aware that he shifted from one letter to the other, or that he shifted from one part to another of large and even small letters in order to see them clearly, or to be able to distinguish them at all. When he covered his good eye and looked with the poor one, he could read only one letter at a time. He was quite conscious that he did not see even the large letters perfectly; but when he practiced shifting with his poor eye, his vision improved not only for the large letters, but also for the small letters. It required considerable time and much patience to convince him that it was impossible for him to see all parts of any letter perfectly at the same time. When he demonstrated that staring lowered his vision, and that shifting improved it, he obtained normal vision in each eye.

### Palming

When palming is done correctly, the vision, memory, and imagination always improve. By palming is meant to close the eyes and cover them with the palm of one or **both hands** without exerting any pressure the closed eyelids. Think of something pleasant, something that you can remember perfectly. Then let your mind drift from one pleasant thought to another. This should be practiced for five minutes ten times daily, or more often when convenient. Some people obtain more benefit by palming for one-half hour, an hour or longer.

There are patients who have difficulty in palming, that is, they strain and make hard work of it. For them it is easier to simply close their eyes and in this way rest them. Other patients obtain relaxation by closing their eyes for part of a minute, then opening them for part of a second, and quickly closing them again. This is called flashing, and usually improves the vision immediately.

It is true that when the eye is perfectly at rest, the sight, memory, and imagination are always normal. Conversely, it is impossible for the sight to be imperfect when the eyes are perfectly at rest. Not only are all errors of refraction benefited and cured by rest, but also organic diseases of the eye,—**glaucoma, cataract, opacity of the cornea, disease of the retina, choroid, or optic nerve are cured by rest and relaxation.**

## Stories from the Clinic

### No. 79: RELAXATION EFFECTIVE

By EMILY C. LIERMAN

WHEN some of my patients are told upon their first visit that glasses will not be prescribed, they wonder what kind of treatment they will receive and they become very much frightened. During my first year of study in clinic work, I noticed that adults, especially, were so frightened that it was difficult to test their sight. Under these trying conditions, a fair test could not be made. Each time the patient was told to read the test card, the retinoscope showed a change in the shape of the eyeball. As I studied each case under treatment, I became convinced that **mind strain had a great deal to do with eyestrain.** I planned a way to approach such patients and put them at ease, and found it effective with adults and children.

I have had many school children under my care who, for no apparent reason, became nervous as soon as they entered school. When I questioned them about their teachers, the answer was usually a favorable one. Sometimes they would complain about some boy or girl whom they feared, and I was able to help them solve the problem. I would find out sooner or later that my patient was suffering from mind strain and fear. It was necessary to convince the patient, after an eye test with the Snellen test card, that it was eyestrain and undue effort to improve in school studies, that caused the trouble. After the vision was improved, there were no more complaints from either the patient or the school officials.

An interesting case was that of a house-painter who spent most of his working-hours on a scaffold, painting the outside of high buildings. He would become so dizzy that he was finally compelled to give up his work. Other jobs were not so easily obtained, and he began to worry because there was no income for his wife and family. He called on a doctor about the dizzy spells and was advised to go to our clinic to have his eyes examined. With the ophthalmoscope, Dr. Bates could find nothing organically wrong with either eye. Dr. Bates said that apparently the man was in general good health. I questioned the patient about his former position as a painter. He told me that his fellow-workman on the scaffold had lost control of himself, had fallen to the ground and been killed. Since that time, the patient had had attacks of dizziness.

Palming seemed to give him relief almost instantly, even though he had his eyes covered for a very short time, a period of five minutes or less. At fifteen feet from the test card, he easily read down to the forty line, but beyond that line the letters were blurred and the dizziness returned. He was instructed to palm again, and while doing this, I told him to remember moving objects. He said it was easy for him to remember an automobile moving slowly, or a street car stopping at a corner, letting off passengers and taking on others. He could imagine boats moving up and down the Hudson River. In this way, we passed on from one thing to another, and after a few minutes of palming, he read the whole card without stopping and without a mistake. I placed my forefinger on the card to guide him in seeing the white spaces between each letter and reminded him to blink as he flashed each letter. The dizziness disappeared and he said that he felt as though a great load had been removed from the top of his head.

During each treatment, I was careful not to mention the scaffold or the accident, but we did talk about paints and colors as he sat with his eyes closed. He seemed eager to explain and I encouraged him to do so. It was interesting to hear him tell how colors were mixed to produce the correct shades desired. His mind became free from strain and his dizziness disappeared entirely. Test card practice was continued both in the clinic and at his home. Later, I added the swing to be practiced with eyes open and with them closed.

One day he came with an interesting story of how he had treated and cured his little son, nine years of age, who was nervous and destructive. Punishing him seemed to make him worse. When his father first practiced the swing, the boy imitated him in fun. Later, it became a natural thing to see both of them swaying and keeping time with the victrola music. Other practices of the Bates Method also became a daily habit to the boy. He especially enjoyed keeping his eyes closed while his father told him of a farm out west where he had lived as a boy.

## Sailors

Faithful practice has given the father normal vision and a relaxed mind, and he has returned to the scaffold and painting with no more attacks of dizziness.

Recently, while crossing the river on a ferry-boat, I stood where I could see the pilot at the wheel and watched him carefully. He was a man about the age of fifty, and did not wear glasses. As we started out of the ferry-slip, we moved slowly. The pilot looked straight ahead and I observed that he blinked his eyes frequently. At first I counted five blinks to the second; then he blinked so often and so irregularly that I could not keep count. I continued to watch him, however, as we crossed the river, and noticed that his head moved about half an inch from side to side and that he blinked his eyes all the time. It particularly interested me to note that when he changed his position a little, perhaps to stand more comfortably, he kept on swaying his body and blinking. The ferry-boat went into the slip as though it were sliding on ice, and there was not the slightest jar as the boat touched the sides of the ferry slip. The pilot had good vision.

Near our office building there is a traffic policeman who manages a steady flow of traffic. He sees things moving all day long. Sometimes his right hand is raised and other times the left, as he halts traffic. He turns his body to the right or to the left, whichever way the traffic is going. His eyes serve him well because he keeps them moving. His whole body appears to be perfectly relaxed, and he demonstrates the efficiency of a relaxed mind.

*The following radio talk was broadcasted from Station WMCA, Hotel McAlpin, on Thursday, July 8th, at 4:15 p.m.*

## "Eye Education"—Blinking

By MAY SECOR

HAVE you a tiny baby in your home? If so, he will teach you how to use your eyes with relaxation. Notice how gently he blinks his eyes—and how often! If you have no baby in your home go to the park tomorrow, and learn your lesson from a baby there. You will notice that when Baby blinks, his eyelids simply drop. He blinks very, very gently.

A new born baby's eyes shift less often than a older baby. The baby's brain, eyes become familiar with each new object it sees, and the eyes shift on the object, eyes, brain become **familiar** with the object, stores a **clear mental picture of the object in the memory**. The next time the baby sees the object it is recognized, remembered, imagined clear, the eyes shift easy, quick on the object and it is seen clear.

Adults also do this; when seeing an object for the first time, it may not be perfectly clear until the eyes shift part to part on the object, figure out what the object is, store a clear memory picture of the object in the brain. Then when the object is seen again, the brain activates fast, perfect eye shifting for that object and it is immediately seen clear.

Now, will you please sit in a very comfortable chair. Rest your feet and the calves of your legs, on a stool which is as high as the seat of your chair.

Let us all palm. Gently close the eyes. Cup the hands, and place them gently over the eyes.

Think of something that is very, very black.

Now imagine that you are watching a tiny baby as he lies in his carriage. See how gently he blinks! And how often!

Now place your hands lazily in your lap. Gently blink, slowly turn your head to the right, as you—

Blink, blink, gently blink, slowly turn your head to the left, as you blink, blink, gently blink; very, very gently blink.

Slowly turn your head to the right, and blink, blink, gently blink; very, very gently blink.

Slowly turn your head to the front, and blink, blink, gently blink; very, very gently blink.

We hope that you have enjoyed this little lesson in Eye Education. Other exercises which will improve your sight are described in Dr. Bates' book entitled "Perfect Sight Without Glasses."

## The Original Nut

By GEORGE M. GUILD

JIMMY was ten years of age and much interested in fairies. One day he was walking along a country road when he saw a great many bees flying among the flowers, looking for honey. Every once in awhile, a bee would rest upon a flower and then almost instantly the flower disappeared and there stood a little fairy, for some of the flowers were fairies in disguise. When they saw Jimmy approaching, they called out to him: "Little boy, little boy, where are you going?"

He answered: "I am looking for The Original Nut"

"And who is The Original Nut, pray?" they asked.

"I do not know, but I am very curious to find him and see what he is like," Jimmy said.

"Why doesn't your father help you?" questioned the fairies.

"He is very busy. He is a policeman, a traffic cop.

When he raises his hand, the automobile drivers stop quickly. If they hesitate or argue, they receive a ticket and have to go to court and see the judge about it."

"Does your father believe in fairies?" they asked.

"No, he thinks fairies are of interest only to little boys and not to big policemen," Jimmy answered.

Then the fairies told him that if he could persuade his father to believe in them, they would help him to find The Original Nut. He promised faithfully to do this and continued on his way. Jimmy had walked a long distance when he became tired and lay down on a mossy, grass-covered bank to rest. After awhile it grew dark. The stars came out, looked at him and winked their eyes. Jimmy was becoming more and more sleepy, but he winked back at them. Then the fairies began to come in large numbers. They danced as they circled about him.

A little while later, the fairies had gone and as Jimmy lay on the grass, he saw a man looking down upon him. It was so dark that he did not recognize him until he spoke. It was his father. He told him all about the fairies and that they had promised to help him to

find The Original Nut if he could persuade his father to believe in them.

Jimmy's father laughed and said: "Why, Jimmy, I do believe in the fairies. They are always happy as they sing and dance, and do all they can to make the world a better place in which to live."

Jimmy jumped up and down in his joy, threw his arms about his father's neck, kissed him on both cheeks, and hugged him tightly. His father placed him on his shoulder and carried him back to his home. Jimmy went to bed and was soon fast asleep. It was not long before he began to dream. He thought he was on the top of a high mountain, looking down upon a large lake at its foot. On the shore of the lake he saw thousands and thousands of fairies happily singing and dancing. With a great deal of difficulty, Jimmie found his way down through the trees which covered the mountain until he came to the shore of the lake. There the fairies were circled about the Fairy Queen. Jimmy ran up to her, fell down on his knees before her, and told her that his father did believe in fairies.

The Fairy Queen smiled and said: "Now, I suppose you want to find The Original Nut. Follow me and I shall lead you to him." Jimmy walked along behind the Fairy Queen as fast as his little legs could carry him, and he had to walk very fast because the Fairy Queen covered the ground with amazing speed,—almost as fast as a horse could trot. After traveling, as Jimmy thought, many, many miles, they came at last to a house which was made of glass. The roof was glass, the chimney was glass, the porch was glass, all four sides of the house were glass and through them one could see the chairs, the tables and all the furniture in the house.

In a rocking chair on the porch sat a queer little man who was cracking nuts with a nut-cracker. As fast as he cracked the nuts, he threw the kernels to a number of glass chickens that surrounded him. Each time a chicken swallowed a nut, all the glass on that chicken was smashed and out of the broken glass a duck stepped. It immediately turned and waddled down to the lake, jumped in and swam across.

The Fairy Queen told Jimmy that the glass chickens were not really chickens, but were little boys and girls in disguise who had been turned into little chickens by an ogre who lived on the other side of the lake. Only The Original Nut could change them back to little boys and girls by first transforming them into ducks. They would then swim across the lake and come out on the other side as little girls and boys, like they had previously been.

When Jimmy awoke from his dream, he found his father standing beside his bed, looking down upon him and smiling. He had a flower pinned to the lapel of his coat. His father pointed to the flower and closed his eyes. Jimmy, with his eyes wide open, saw that the flower was the Fairy Queen who smiled at him. She removed the pin from the stem of the flower and the coat. The fairy then climbed down to the floor and waved her hand to Jimmy and his father and beckoned them to follow her, which they were glad to do. Although the fairy was very small, she ran so fast that they had all they could do to keep up with her. They passed through the chicken yard which was filled with glass chickens, all anxious to go along also.

The Fairy Queen soon led them to the shore of a lake, which oddly enough, seemed to be the same lake that Jimmy had dreamed about. There were the same fairies, thousands of them. The Fairy Queen with her magic wand led them to the foot of the mountain to the same glass house with The Original Nut busily cracking his magic nuts with the same magic nut-cracker. The Original Nut was glad to see them and greeted them joyously.

Surely dreams come true, especially to little boys who have loving, kind fathers who are traffic cops and are busy many hours of the day, doing all they can to make everybody safe and happy.

## Questions and Answers

Q—What is **retinitis pigmentosa**?

A—Retinitis pigmentosa is a disease of the interior of the eye, in which small areas of the retina and other parts of the eye are destroyed. They are replaced by small black pigment patches.

Q—Can **opacity of the cornea** be cured?

A—Yes. The treatment which is most beneficial is the sun treatment as described in "Perfect Sight Without Glasses," by W. H. Bates, M.D.

Q—Are all cases of **squint** curable without glasses or an operation?

A—All cases of squint or cross-eyes are curable by the Bates Method.

Q—Is it possible to cure squint in a child under two years of age by the Bates Method, and what is the treatment employed?

*Squint, crossed/wandering eye treatment*

A—A child, two years of age or younger, can be treated and cured of squint, with or without imperfect sight, by the Bates Method. The treatment is varied. The swing can be practiced by the mother holding the child in her arms. If the child is able to stand or walk, it is held by the hands and the sway is practiced with the child moving from side to side. Keeping time with music encourages the child to continue the swaying for a longer time.

Improving the memory and imagination is also recommended. The child is encouraged to play with toy animals and is taught the names of the different animals. Usually the animals are placed on the floor in groups and the child is asked to pick up the animals as they are named. As the child reaches for one and then another, the parent may observe whether the child goes directly toward the toy or reaches to either side of it. This method is used in extreme cases of squint where the child does not see perfectly where it is looking.

Colored yarns are also used in these cases. The child is taught names of the different colors. An improvement is always noted after such treatment because the child is constantly shifting his glance from one colored skein of yarn to the other as he selects the one called for. The problem is to educate the eyesight. The more the eyes are used, the better.

Palming is beneficial in the cure of squint. If the child is told that it is just a game of peek-a-boo, he immediately becomes interested and enjoys it. Reading a story to the child so he palms is usually beneficial, and improves the squint.

With children three years or older, the Pot Hooks card is used. This is a test card with the letter "E" pointing in various directions. The child tells whether it is pointing up or down, left or right. If a mistake is made, palming is introduced in order to rest the eyes.

Children with squint are usually unruly, disobedient, or destructive. When the squint is improved, a change in their conduct is also noted. They become quiet, obedient, and their mental efficiency is improved.

Q—Is **diabetic cataract** curable?

A—Diabetic cataract is curable when the general disease of diabetes can be relieved by treatment.

In other articles Dr. Bates tells how eyesight was improved even when the diabetic condition was not cured. Correct diet, and use of Bates method improves the health of body, mind and eyes.

Q—After a serious illness eight years ago, my pupils became very large. Is there anything you can suggest that will help them to contract?

A—Dilated pupils are not usually symptoms of disease of the eye. The sun treatment is beneficial. Sit in the sun with the eyes closed, allowing the sun's rays to shine directly on the closed eyelids, moving the head a short distance from side to side to avoid discomfort from the heat. This should be practiced for a half-hour, an hour, or longer.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

OCTOBER, 1926

### Demonstrate

1. That a strain to see at the distance produces near-sightedness. Look at a Snellen test card at twenty feet and read it as well as you can. Now strain or make an effort to see it better, and note that instead of becoming better, it becomes worse.

2. That a strain to see at the near point does not increase near-sightedness, but always lessens it. Modern teachers state that straining the eyes at any distance can cause blur at all distances. Use the eyes relaxed at all distances for clear vision at close, middle, far distances.

Look at a card of fine print at six inches from your eyes and read it as well as you can. Now make an effort to see it better, and note that your vision for the near point is lowered, while the ability to read the fine print at a greater distance is improved.

3. That when a mental picture is perfect with the eyes closed for part of a minute or longer, a perfect mental picture can be remembered, imagined, or seen for a second or less with the eyes open.

Remember a black kitten. If your mental picture is gray or an imperfect black with the eyes closed, imagine that you are pouring black ink or black dye over it. Note that the clearness of the mental picture improves.

Look at a page of fine print. Then close your eyes and imagine the white spaces between the lines to be perfectly white. If they appear to be a grayish white, imagine that you are painting the white spaces between the letters, inside the letters, and between the lines, with white paint or whitewash. Then open your eyes for a fraction of a second and note that the white spaces between the lines will appear whiter, if you do not make an effort to see either the black letters or the white spaces.

White paintbrush with white paint. Paint the white spaces between sentences, inside letters with the imaginary white paintbrush.

Trace on/along the edge of the tree with the end of the imaginary nosefeather. Nosefeather can also be imagined invisible.

## Lord Macaulay

By W. H. BATES, M.D.

LORD MACAULAY, who will always hold an eminent place among English men of letters, was born October 25th, 1800 and died December 28th, 1859. Before he was 30 years of age, he became a member of the House of Commons, and later held positions of trust and importance which required him to visit different parts of the world. At one time he wrote a code of laws for the benefit of the people of India and devoted considerable time to the work.

Lord Macaulay was said to be the most rapid reader on record, and had the ability to remember perfectly what he had read ten or more years previously, without refreshing his memory by re-reading it. He was able to read a page of five hundred words in one second. Not only could he remember the words that were spelled correctly, but also those words which were spelled incorrectly. He was able to remember the page on which they could be found, the line of the page, the location of the words on the line, and how each word was misspelled. For example, if the word "which" were misspelled, he could remember that it was the fourth word on the fifth line on page 120, and that it was spelled "whiche." This seems a remarkable statement to make, but I have had patients who became able to read almost as rapidly as Lord Macaulay after a course of eye education. This training consisted of central fixation and the imagination of the halos, i.e., the white spaces inside the letters, between the letters and between the lines of letters.

Central fixation is the ability to see best where you are looking and not so clearly where you are not looking. This requires shifting from one part of an object to another part. To have perfect sight, Lord Macaulay unconsciously practiced central fixation. If he had consciously tried to see a letter or to keep his attention fixed on one part of a letter, or if he had tried to see all parts of a letter at once, his vision would have been imperfect. To see the top of a letter perfectly, it was necessary for him to look at and see the top of the letter best, and the rest of the letter not so well. To see each of the other sides perfectly, it was necessary for him to look at and see each side best, and the rest of the letter not so well. Since the average number of letters in each word is five, he shifted four times five, or twenty times, to see each word with maximum vision. **To recognize five hundred words, it was therefore necessary, for him to shift five hundred times twenty, or ten thousand times in one second.**

(Includes saccadic, microscopic, high frequency and other natural shifts, eye movements.)

In order to see perfectly, it is necessary that one imagine perfectly. Macaulay remembered or imagined the white spaces between the lines to be whiter than they really were. When the white spaces were imagined perfectly white, the black letters were imagined perfectly black, because the white spaces could not be imagined perfectly, without the black being imagined perfectly at the same

time. For the same reason, when the blackness of the letters was imagined perfectly, the form of the letters was also imagined perfectly. It has been demonstrated that trying (using effort, staring, squinting) to see the black letters is a conscious strain, or is attended by a conscious strain, and always lowers the vision.

It is a truth that one cannot remember a letter perfectly unless it has been seen perfectly. When the memory for one letter is perfect, the memory for all letters is also perfect. A letter cannot be imagined perfectly unless it has been remembered perfectly. It cannot be seen perfectly unless it has been imagined perfectly. We see only what we imagine we see. The speed of reading is greatest when the vision is perfect.

After a course of eye training, some of my patients were able sub-consciously to remember large letters of the Snellen test card, which they had previously regarded, without being conscious of distinguishing any of the letters. Many of these patients have become able to remember or imagine small letters of the test card at thirty, forty, or fifty feet. I have had some patients glance for a few seconds at a page of diamond type at ten feet or further, without consciously reading any of the letters. With their eyes closed and covered with the palms of their hands, some of them became able to remember or imagine one or more letters of the fine print. They must have unconsciously seen the fine print to have been able to imagine the letters, because one cannot imagine something not remembered, and one cannot remember perfectly unless one has seen perfectly. Therefore, in order to imagine a letter perfectly, it is necessary that the letter be seen previously, either consciously or unconsciously.

The method of rapid reading practiced by Macaulay is invaluable and should be more widely employed.

Some types of speed reading causes vision impairment

In my Writings I have remonstrated against the methods employed to teach rapid reading. The usual procedure was to encourage the student to see all of the letters of a word at once, or to see all the letters of a paragraph of words at the same time. This was accepted as the correct method and very intelligent scholars have recommended it. My research work has proved that there is nothing more injurious to the eyes than to make an effort to see a whole letter or a whole word, all parts equally well. If one looks at the first letter of a word, the last letter is not seen perfectly at the same time. If an effort is made, the whole word becomes blurred and may not be distinguished. The stronger the effort that is made, the more injurious it is to the mind and eyes.

In the public schools of the City of New York, teachers are advised to practice this method of rapid reading with young children. Although the result is unsatisfactory, many teachers still persist in their efforts to teach the impossible. It is interesting to know that children who have perfect mental pictures of letters, or other objects, have a normal memory or a memory that is just as perfect for letters or objects. The scholarship of such children is much better than that of others whose memory or mental pictures are imperfect. A number of school children have told me that at the time of their examinations, they could read a question on the blackboard and have no conception of what the answer might be, but if they closed their eyes and remembered the first letter of the question perfectly, it helped them to remember the answer to the question.

One teacher with a class of children who were mentally deficient, found that the practice of central fixation, palming, and the use of the imagination was of great benefit to the minds of those children. A school teacher in Chicago has made a practice of teaching her pupils how to imagine things perfectly, with the result that no matter how ignorant they may be, at the beginning of the school term, it is not long before they become able to make the same progress as other children in the rapid advancement classes.

The dean of the department of metaphysics of one of our prominent universities came to me and complained that he was suffering with all kinds of mental and eye troubles because he had lost the power of concentration. The strain was so great that he was compelled to give up his work. Glasses were of no benefit. He demonstrated that to concentrate on one letter or one part of a letter it was necessary for him to make an effort, and in a few seconds his vision became very imperfect.

With perfect sight, no effort is made and the eyes and mind are at rest. There is no fatigue, and one can read with great rapidity for many hours continuously, without being conscious of having eyes.

Looking down to read, head, neck bent down, lowers blood, oxygen flow to the brain, eyes, lowers the memory, imagination, brain function, clarity of vision. Use a book holder to keep the head, neck up straight.

## Stories from the Clinic

### No. 80: FEAR

By EMILY C. LIERMAN

FEAR is one of the many symptoms which accompanies imperfect sight. This is more noticeable in adults than in children. If pain results from imperfect vision, the fear is much greater. Many of our patients have been to other clinics, or other doctors, and were told that if glasses were not worn, they would go blind. Sometimes they were told that they had an organic disease of the eyes, such as glaucoma, iritis, keratitis, atrophy of the optic nerve, or cataract. The patient has cause to fear. It is my belief that the doctor should tell his patient what the trouble is; but when he is not absolutely sure of his diagnosis, he commits an error in telling the patient something which he himself would be afraid to hear. Such cases are numerous, and Dr. Bates and I both know that they come to us feeling that it is their last hope. Their fear is always noticeable.

A case which is worth mentioning is that of a woman over fifty years of age, who came with little hope of being cured. She had been treated and fitted with glasses by several eye-specialists without any relief of pain or improvement in her sight. Two doctors who had examined her, said that all her pain was caused by glaucoma, which she had in both eyes. She said that she had a constant fear of going blind, and many times had a strong desire to end her life. The effort to conceal this desire from her family, who loved her dearly, produced more tension and strain.

Dr. Bates examined her eyes thoroughly and said that there was no opacity of the lens or other parts of either eye. Both optic nerve and retina were normal. Her vision of the test card, with each eye separately, was 10/40. Although the letters were blurred, she could tell what they were. I noticed that she stared a great deal as she explained her trouble to me. Since palming usually stops the stare with most patients, I taught her to palm, being sure to keep up a steady flow of conversation in order to distract her attention from her eyes.

I knew that she had been studying Dr. Bates' book, "Perfect Sight Without Glasses," and I asked her what she thought Doctor meant in his book by mental pictures. She said that she had no mental pictures while her eyes were closed and covered. I knew then that she made an effort to imagine things with her eyes closed, so I did not mention mental pictures again. However, I did not get away from the subject, but, while talking, I mentioned the color of the dress which she wore, and asked her if she could remember the design in the trimming of her dress. She explained the design accurately. Then I asked her which she thought was the whitest

white, a white cloud in a blue sky, or a drift of snow. She answered that she could think of nothing whiter than the white of snow. All this time, I believe that she had had mental pictures of the white cloud and the snow, as well as the design in the trimming of her dress. While her eyes were still covered, I asked her if she had any pain. She said no, that she had forgotten all about it.

She was then taught to sway her body, while standing with her feet about one foot apart. She did this very gracefully. I told her to keep up a constant blinking of her eyes as she swayed from side to side, getting a glimpse of the letters of the test card ten feet away. She was instructed to look at only one letter at a time and to quickly look away from the card to avoid the tendency to stare or strain. We continued to practice this for ten minutes and in order to keep up her interest, I swayed with her all the time. Her vision improved to 10/20 and she said every letter was clear and distinct.

In treating her again the next day, I used a different test card, the Pot Hooks card with the letter "E" pointing in various directions. She had faithfully carried out instructions which had been given her for home treatment, otherwise she could not have gained as much as she had in so short a time. Her vision with each eye separately was 10/15. Other cards were used, but she did not read them so well. Sometimes this happens, especially with patients as nervous as she.

It is strange that some of us have likes and dislikes, even with an ordinary test card. This fact ought to convince school nurses and doctors, that when children's eyes are being examined with the various test cards, they cannot do so well with some cards as they can with others. A person with an unsympathetic mind would scoff at the idea that a test card could make a difference in the vision, but it is a fact which can be demonstrated.

To vary her treatment, I used a small test card with the fundamental principles of the method, written by Doctor Bates, on the opposite side. The letters on this card are printed in unusually large reading type at the top of the card, and they gradually decrease in size to very fine print, or diamond type, at the bottom of the card. When she first took the small card, she held it at arm's length in order to read the largest type on the card. Rather than worry her by telling her to hold the card closer, I took her out in the sunshine, told her to close her eyes, and gave her the sun treatment with the sun-glass. At first she drew her head away, indicating that she did not like it. In a soft tone of voice, which I had used from the beginning, and which I realized helped to alleviate her nervousness and fear, I suggested that she let me try it again. I told her that babies enjoyed the sun treatment, when the sun-glass was used on their closed eyes. I explained how many of our boys, who returned from France, after the war, enjoyed this wonderful sun treatment which Dr. Bates had discovered was so beneficial for all sorts of eye troubles. During all the time that I talked with her, I used the sun-glass on her eyes. I noticed that she responded, because her body relaxed and she settled in a more comfortable position in her chair. When I stopped the movement of the sun-glass for a moment, she immediately asked for more, so I continued using it on her closed eyes for more than twenty minutes. After this treatment she read three sentences of the fundamental card, at eight inches from her eyes. The type of the third sentence is about the size of book type.

During her third treatment, she smiled most of the time, whereas she had been very sad before. She suggested that I test her sight with a strange test card. By swaying her body from side to side, as she stood twelve feet from the card, she read the ten line letters, one at a time, looking away from the card after seeing each letter.

Having watched her carefully, I noticed that at times she forgot to blink. When she finished reading the card, and complained of a burning in her eyes, I reminded her that she had not been blinking often enough while reading the test card. She then practiced blinking often, just as the normal eye does.

I believe, she will always remember the next treatment she had. The balcony which surrounds our office is a delightful place on sunny days, and I gave her sun treatment there for almost half an hour. Then we turned our backs to the sun, and I placed my book, "Stories From the Clinic," in her lap. Before she started to read, I took one of the **small black test cards, with white letters**, and put it on the opposite side of the page which she was reading. **By looking at a white letter of the test card, she began immediately to read sentence after sentence of the book.** For the first time in twenty years, she was able to read book type without glasses. During her last treatment, she read words and numbers in the telephone book. Her pain was gone; she no longer wished to die, and she is now a happy woman, because she can read her books without the aid of glasses.

Sway side to side, blink, relax and 'flash', (shift for a fraction of a second) on a letter on the eyechart, 10 feet away.

Sunlight, Sunning and Sun Treatment.

Read fine print in the sunlight.

## Case Reports Blind Aunt Kate

We take pleasure in publishing the following letter from a patient of Dr. Bates.

My dear Dr. Bates:

May I take a few minutes of your time to read something very interesting which I am eager to tell you?

It is the case of a smart old lady of 86. She is called "Blind Aunt Kate" and I thought when I met her, that she must be totally blind, as I saw her grope her way along. She was unable to distinguish me from some one else although my face was within six inches from her face. A week ago today, August 29th, I tested her eyes outdoors in the sunlight. At first she was unable to see the large E on the black card; then she read it at eight inches, and later at eighteen inches. After palming for five minutes, she distinguished it at twenty-eight inches and at thirty-six inches; after palming again F and P came out at eight inches, and after palming again, at twenty-six inches. The following day she saw L, P, E, D, at thirty-five inches and the large E at sixty-six inches. Also she was able to see all the rest of the lines at various distances and two letters of the very last line at six inches. Today is dark and rainy, but she showed great progress after one week's work. Indoors, she could distinguish the large E at seventy-six inches; E, P, at sixty inches and T, O, Z came out still more clearly at sixty-nine inches. Also through the rain she could see the barn, a wagon in the yard, the path and road and a stone fence following the road, things which she hasn't been able to see on a bright day for over a year. She also distinguished different faces (including mine), half way across a large room.

She is so happy over her week's improvement, she says if she can see this well for the rest of her life, she won't complain. She is very faithful in her work and would gladly do anything more that I would suggest, but I have been afraid of directing her wrongly,

though I have done nothing but have her palm, blink frequently (she has been staring so persistently), swing her eyes horizontally, and see things moving by as she walks.

Her eye doctor here used to call her trouble an enlargement of the eyeball, and said glasses would do her no good. She wore glasses for forty-five years and took them off a year ago. She has not read, even coarse print in four years. She says for the past two months her eyes had failed so rapidly that she was trying to resign herself to utter blindness. She is a very sweet, patient old lady and is quite unhappy from outside influences, so I am very eager to give her all the help for her eyes I can. It almost seems as if my Mother's spirit has led me right to her. If you could give me some special exercises for her to follow, I could help her even more, I'm sure, in the two weeks remaining of my vacation. On a bright day she can see every letter of the black E card. I am just beginning to work with her on the white card but today indoors, she could read the first three lines as far off as on the black card. I did not test her on the rest of the lines.

Hoping I am not asking too much of an already busy man, and thanking you, I remain

---

The following letter came a few days later.

Dear Dr. Bates:

Your very encouraging letter was received and made both Aunt Kate and myself very happy. I should be very glad indeed to have you publish her story, and she says too, that it would make her so happy if she thought someone else might be helped through her experience.

She has been ill for two days so that I had to discontinue the work on the card. She has, however, kept resting her eyes and at 6 o'clock this evening, when it was very gloomy, we sat at an upper window together and she suddenly remarked: "Now, I can see that old stone wall across the road so plainly!" I hope tomorrow we can resume the work with the card.

I wrote you on September 5th, which was, I believe, a dark day and just one week from the day I first tested her eyes. The next day was sunny again and I tested her eyes with this result, which you will agree was splendid. The large E she saw at 174 inches; F, P at 136 inches; T, O, Z at 142 inches; L, P, E, D at 78 inches; P, E, C, F, D at 53 inches; E, D, F, etc. at 41 inches. (All but Z, which she saw at 35 inches), D, E, F, P, etc. at 18 inches. The last two lines she made out entirely by holding the card closer to her eyes. So, according to my most careful measurements she saw the various lines at from five to ten and seventeen times the distance she saw them eight days previous.

I am telling you this in such detail so that you will realize there is no mistake in my previous story. I measured the distance so carefully on each occasion. You may also make use of these latest figures in your magazine account of Aunt Kate if you wish.

Sincerely yours,  
ALICE AVERY PRICE,  
159 So. Broadway, White Plains, N. Y.

## Cured in One Visit

A report from Miss Anna Woessner, Teacher of Dr. Bates Method

MADLINE, aged 12, had very poor vision for things up close, and in school was unable distinguish figures on the blackboard. Outdoors, all objects at 20 feet or further, were blurred to her. She had worn glasses for a year and they constantly annoyed her. When she heard about the Bates Method of treatment, and that I was treating patients, she was eager to obtain help from me so as to discard her glasses, if possible. When I met her, the only test card available was a small letter card with the fundamentals by W. H. Bates, M.D. printed on the opposite side. The test card begins with the letter C which can be seen clearly with the normal eye at fifty feet. Madeline could not see even this letter clearly at five feet. While palming I asked her to describe her doll to me. Then she told me about her bicycle and imagined it was moving with her, as she was riding. Before she opened her eyes to look at the card, I put it off at a distance of eight feet and told her to stand, open her eyes, sway her body, and while blinking to look at the card, then at a bird-cage near by. Without a stop she read up to S, C, G, O, or the letters, which are seen by the normal eye at fifteen feet. With more practice of this kind, her vision improved from the third to the bottom line at nine feet away. These letters are read by the normal eye at four feet.

Sun treatment was given her which she enjoyed, and this helped to improve her near vision, so that she could read the finest print of the fundamentals on the opposite side of the small test card. Madeline had just one treatment. Greatly encouraged, she promised to practice often every day and not put on her glasses again. One month later I saw her again, but she did not need another treatment. Her vision was normal at the near point, as well as for the distance.

Madeline's sister Regina is 15 years of age. She has **congenital astigmatism** and, although she has worn glasses for ten years, she still "hates them." Without glasses, her eyes were mere slits. Her vision was 10/40 with the left eye and 10/30 with the right. After impressing her with the importance of shifting and blinking (which she had been very careful not to do), I gave her a short period of sun treatment. At first this was very distressing, as she was unable to open her eyelids for even a moment. After swaying, with closed eyes, this was overcome, and at the end of the treatment she read the greater part of the 10 line.

After several more treatments, her vision became practically normal. She is continuing her treatment under my supervision, and after a few more I feel confident that her vision will be normal.

Anyone wishing to confer with Miss Woessner, can reach her by calling New York, Murray Hill 8446, or by writing her at her home in West Nyack, N. Y.

### "The Swing"

All things are in Motion;  
Let's fall into time,  
And Swing along with them,  
While chanting this rhyme.

Well keep our swing steady,  
By Grandmother's Clock,  
Its pendulum swinging,  
Its measured tick-took.

In Memory I'm seeing  
A fine old elm tree;  
Its low-hanging branches  
Seem beck'ning to me.

A brown bird sits rocking  
On that topmost limb.  
I wonder who taught  
The Bates System to him.

With eyes all a-sparkle,  
Face turned to the Sun,  
His head ever turning,  
His day is begun.

White clouds float above him  
In limitless blue;  
His wee throat is swollen  
With song, the day thru.

Teach us, then, oh brown bird,  
To start our day right;  
That our Eyes like yours,  
May be sparkling and bright.

Written by Mrs. A. J. Campbell, patient of Dr. Jean B. Claverie, Chicago, Ill.

### Questions and Answers

Q—What causes redness and smarting sensation of the eye even when plenty of sun treatment has been given? Should one continue with sun treatment under the circumstances?

A—Take the sun treatment frequently for five or ten minutes at a time daily, increasing the length of time until the eyes become accustomed to the sun. The eyes should always be benefited after the sun treatment, and one should always feel relaxed. When done properly, the redness and smarting should soon disappear. If the eyes are not benefited, it is an indication that you strain while taking the treatment. Alternate the sun treatment with palming or closing the eyes to rest them.

Q—What makes the eyes seem extremely heavy upon rising in the morning?

A—Eyestrain while sleeping. See the May number of "Better Eyesight" on Presbyopia.

Q—What causes a white matter to appear in the corner of the eyes after the sun treatment?

A—The white matter in the corner of the eye is produced by infection, and is cured by the sun treatment.

Q—Is it harmful to sit facing the sun, while reading a book in the shade, thus getting sun treatment?

A—To sit facing the sun, while reading a book, is not injurious to the eyes, provided the patient is comfortable. Some people become uncomfortable, which produces a strain, and the sun is of little benefit under such conditions.

Try with the sun behind you, shining on the back, over the shoulder onto the book.

Q—Does sun treatment have to be continuous to be effective, or can short spells be substituted?

A—Sun treatment does not have to be continuous. Short periods are equally beneficial.

Q—Is resting the eyes by palming a more effective cure for smarting of the eyes than the sun treatment?

A—This depends upon the individual. Some are benefited more by palming, while others receive more benefit from the sun treatment.

Q—Should sun treatment be moderated due to the heat of the sun—as in the tropics?

A—Take as much sun treatment as you can with the eyes closed while slowly moving the head a short distance from side to side to avoid discomfort from the heat. Should it make you uncomfortable and nervous, lessen the length of time that the sun treatment is employed.

Q—Is smoking in moderation injurious to the eyes?

A—Smoking in moderation is not injurious to the eyes. I disagree: Smoking is a main cause of health impairment, lowers circulation, blood/oxygen to the brain, ears, eyes, causes many eye problems, including glaucoma.

Q—Should motor goggles be worn as protection against wind?

A—No protection is needed against the wind if the eyes are used correctly. Blinking, shifting, central fixation, and the imagination of stationary objects to be moving, should be practiced while motoring, and, in fact, all the time. Motor goggles weaken the eyes and make them sensitive to the sunlight.

Goggles protect the eyes from eye injury from insects, other debris flying into the eyes.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

NOVEMBER, 1926

### Demonstrate

That by practicing you can imagine a letter at ten feet as well as you can see it at one foot.

Regard (shift on) a letter of the Snellen test card at a distance where it cannot be readily distinguished and appears blurred. Now look at (shift on) the same letter on a card at the near point, one foot or less, where it can be seen perfectly. Then close your eyes and with your finger draw the same letter in the air as well as you can remember it. Open your eyes and continue to draw the imaginary letter with your finger while looking for only a few seconds at the blurred letter on the card at ten feet. Then close your eyes again and remember the letter well enough to draw the letter perfectly in your imagination with your finger. Alternate drawing the letter at ten feet in your imagination with your eyes open and drawing it with your eyes closed as well as you see it at one foot or nearer. When you can draw the letter as perfectly as you remember it, you see the letter on the distant card in flashes.

By repetition you will become able not only to always imagine the known letter correctly, but to actually see it for a few seconds at a time. You cannot see a letter perfectly unless you see one part best, central fixation. Note that you obtain central fixation while practicing this method, i.e., you see one part best. Drawing the letter with your finger in your imagination enables you to follow the finger in forming the letter, and with the help of your memory, you can imagine each side of the letter best, in turn, as it is formed. By this method the memory and the imagination are improved, and when the imagination becomes perfect, the sight is perfect. **You can cure the highest degrees of myopia, hypermetropia, astigmatism, atrophy of the optic nerve, cataract, glaucoma, detachment of the retina and other diseases by this method.**

## Detachment of the Retina

By W. H. BATES, M.D.

### Occurrence

IN DETACHMENT OF THE RETINA, the inner coat of the three coats of the eyeball become separated from the other coats. At first only a small part of the retina may become separated, but later the detachment may increase in extent until the whole retina is separated from the other parts of the eye. In the early stages, the sight may be good and remain good for some months and even for some years. Usually the patient complains of a loss of vision almost from the beginning.

Detachment of the retina occurs frequently in high degrees of myopia. Some statistics report that one-third of all cases of extreme myopia sooner or later develop detachment of the retina, at first in one eye and afterwards in the other eye. However, it may occur in normal eyes without any inflammation of the other coats. The detachment, which is observed covering tumors of the eyeball, usually presents a different appearance from other forms of detachment. Detachment of the retina is a rare disease. "Galezowski found it in 5/10 of 1% of ophthalmic cases. It is supposed to be caused by muscular exertion, coughing, sneezing, vomiting, anger, or fear. Injuries of the eyeball cause a small proportion of cases." (Ball.)

I believe that mental or ocular strain is the principal cause.

Detached retina is often caused by a progressively lengthened/elongated eyeball shape (Myopia) caused by increased outer eye muscle tension and mental strain resulting from stronger and stronger eyeglass lenses. The abnormal lengthened eye shape causes increased pressure, pulling, stretching on/in the eye, cornea, lens retina, optic nerve resulting in retina detachment, cataracts, cornea ulcers and other eye problems.

Progressively shortened and/or irregular eye shape (farsight/astigmatism), due to increased outer eye muscle tension, mental strain caused by stronger and stronger glasses for close distance can also cause detached retina.

If the eye has had a treatment/operation for detached retina, will the Bates Method help it heal as Natural Eyesight Improvement returns the eye to normal shape, removing pulling, tension, stretching on/in the eye/retina or will it interfere with the surgery? Ask your doctor. The Bates method can help to prevent detached retina by keeping the eye healthy, preventing eye muscle tension and abnormal lengthening, shortening... of the eye. Avoiding eyeglasses is the main way to avoid detached retina caused by Eye muscle tension, abnormal eye shape caused by stronger and stronger eyeglasses.

Distant card letter C is unclear.  
+Look at, shift on the identical clear letter C on the close card.  
+Next: Close the eyes. Remember, imagine and draw with your finger in the air the clear letter C that was seen on the close card.  
+Open the eyes, continue to draw the letter C and look at, shift on and imagine clear the distant card's blurry letter C for a few seconds.  
+Close the eyes and draw the letter C with the finger again perfectly clear in your imagination.  
+Eyes open, shift on the distant C again while drawing and imagining the C clear.  
+Repeat.  
+Look at the clear letter C on the close card occasionally to reinforce the clear memory, mental and visual image of the clear letter C. The distant C will be seen clear.

Far-blurred

Close-clear

Abnormally lengthened eye. Tension, pressure, stretching on/in the eye, retina, lens, cornea... due to outer eye muscle tension, stronger and stronger eyeglass lenses. Can also be caused by head/eye injury.

## Symptoms

"In the beginning, the symptoms of detachment are periodical dimness of vision, flashes of light and the appearance of sparks, **dust or soot before the eyes**. The field of vision becomes less and there may be the appearance of a cloud or **floating specks before the eye**. Patients have complained that they can see only a part of an object at a time. So long as the center of sight is not involved, the vision of objects straight ahead is good. Sometimes the detached retina may functionate for a time, producing **vertigo**. In uncomplicated cases, there is no pain." (Ball.)

## Orthodox Methods of Treatment

Ball in his "Modern Ophthalmology" states:—"The treatment of retinal detachment is an unsatisfactory—in fact, almost hopeless—task. While in a few rare instances the retina has become reattached spontaneously, and a few recoveries have followed the administration of saline purgatives, and some cures have followed the internal use of mercury, iodid of potassium, and salicylic acid, the majority of successful results thus far reported have been attributed to surgical intervention. Surgical intervention, proposed by Sichel in 1869, has assumed numerous forms: simple puncture of the sclera and chorioid (Sichel), dissection of the retina (Von Graefe), drainage by a fine gold wire passed to the chorioid by means of catgut (Galezowski), dislaceration with two needles (Bowman), iridectomy (Galezowski and others), injection of iodin into the subretinal space (Galezowski, Gelpke, Scholar), electrolysis (Gillet de Grandmont), cutting of vitreous bands and transfixion of the eyeball (Deutschmann, Jaencke), injection of a 3.5 per cent strength solution of gelatin in a physiologic salt solution between the sclera and capsule of Tenon (de Wecker), puncture of the eyeball with the galvanocautery (Galezowski, Abadie), injection of normal salt solution into the vitreous after evacuation of subretinal fluid (Walker), and injection of air into the vitreous (Jensen). Most of these procedures should be ruled out of the domain of modern ophthalmology. All are dangerous to the integrity of the globe, and one of them—intra-ocular injection of iodin—has been followed by meningitis and death."

Holth (Wien. Med. Woch., Feb. 3, 1912) claimed that in cases of detachment of the retina, a piece of the sclera was excised from the eye without injuring any of the coats of the eye (chorioid). The hardness of the eyeball was then diminished for some weeks or months, and in two cases the detachment of the retina disappeared, and the field of vision became enlarged but vision itself did not improve. The most important point was that in one case the myopia decreased from 18 Diopters to 5 Diopters, in another from 16 Diopters to 10 Diopters and in a third case from 12 Diopters to 5.5 Diopters.

The author explains the effect of the operation as follows: "In the first months after the operation subchorioidal lymph oozes through the opening in Tenon's capsule and on account of this the absorptive capacity of the chorioid is increased. By the traction of the outer eye muscles, the walls of the myopic eye become compressed, and the myopic refraction becomes diminished."

## The Writer's Method of Treatment

The results of the preceding methods of treating detachment of the retina as well as of many other methods which are not reported, have been practically of no benefit. It is my desire to call attention to the fact that detachment of the retina is curable because it has been cured. In the course of a lifetime, most ophthalmologists have seen one or more cases of detachment which recovered spontaneously, or without any treatment. This fact suggests that if some patients recover without treatment, detachment is curable under certain conditions. It can be demonstrated that the **cause of detachment of the retina is a mental strain and is not necessarily due to an injury to the eye by a blow**. If it is due to mental strain, relaxation of the mental strain should be followed by a benefit. In all cases of retinal detachment which I have observed, **relaxation methods of treatment have always been followed by an improvement or a cure of the detachment**. These methods of obtaining relaxation are those which are unconsciously practiced by the normal eye, when the normal eye has normal vision. For example, the stare or the effort to see distant or near objects, always causes imperfect sight. Rest or relaxation of the eyes is always a benefit to those with imperfect sight. The normal eye is moving all the time, and an effort to keep the normal eye stationary is always followed by imperfect sight. People with normal eyes and normal sight are always moving their heads and eyes from one point to another, and do not look fixedly at any one point continuously.

One can rest the eyes by blinking without necessarily staring or straining. To keep the eyes wide open continuously always makes the sight worse. Patients with detachment of the retina use their eyes in the wrong way, just as near-sighted people use their eyes incorrectly. In many cases of detachment, the patients suffer from the annoyance of bright sunlight. By gradually accustoming the eye to the sun, the symptoms of retinal detachment usually improve.

## Cases

A sharpshooter came to me for treatment of detachment of the retina. He said that when he saw the bull's eye at 1000 yards, it appeared to be moving. When he tried to stop the movement, the effort made him very nervous and his sight became so imperfect that he could not see the bull's eye at all. When he allowed the bull's eye to move, the score was better. At that time, he spent so many hours at target practice that he became very nervous and tired. The interesting fact was that the left eye which was not used in aiming, developed detachment of the retina while the right eye, which was used almost constantly, remained normal. If the detachment were caused by eyestrain, we would expect the eye which was used to be affected. On the contrary, the eye that was not used developed detachment of the retina. It was the strain of his mind, and not the strain of his eyes which caused the retinal detachment.

The dark glasses which he was wearing to protect his eyes from the sun, were so strong that they seriously interfered with the vision of his good eye. The left eye had very disagreeable symptoms. He imagined he saw red, blue and other colored lights. All the treatment that he had received in the hospital had not relieved these sensations. These lights disappeared after he had practiced the various swings for many hours daily. Subjective symptoms disappeared first, and when he became able to obtain a considerable

amount of relaxation, the objective symptoms or detachment then disappeared. The treatment which brought about this result was much the same treatment that is employed in the cure of myopia, astigmatism, far-sightedness, or squint. Relaxation or rest was very beneficial. Palming was particularly helpful. Any treatment which promoted relaxation was always followed by an improvement in the detachment of the retina.

A patient suffering from a high degree of myopia, which was progressive was suddenly afflicted with detachment of the retina in one eye. He received the usual orthodox treatment from a number of ophthalmologists living in Pittsburgh, New York, Chicago, and other places, but without any benefit. When he finally came to me and was treated by relaxation methods for the relief of the high degree of myopia, the detachment became less and the myopia decreased. Considerable relaxation was obtained by the practice of the optical swing, which has been described many times in this magazine. He was first treated on July 30, 1925. The vision of the right eye was 8/200, while that of the left eye, which had the retinal detachment, was only 1/200. Looking straight ahead with his left eye, his vision was imperfect. At times he had some vision, for a few seconds only, while looking straight ahead.

His visits to the office were irregular. On October 17th, 1925, after three month's treatment, the vision of the right eye had improved to 15/200, while that of the left eye was 15/200 plus. After the long swing, the vision of the right eye immediately improved to 15/100, while that of the left eye improved to 15/100 plus. With the ophthalmoscope, the **retina appeared reattached and was otherwise normal.** The field of vision was normal.

The patient returned home very much pleased. However, he made a mistake, I believe, in calling on some of the eye-specialists whom he had previously consulted, and who had all pronounced his imperfect vision from the detachment to be incurable. Some told him that they must have made a mistake in diagnosing his case, because if he had had detachment of the retina, the eye would not have recovered. They believed that all the other men who had made the diagnosis of the detachment of the retina, had also made a monumental blunder. This would have been perfectly satisfactory, but unfortunately the patient neglected the treatment I had prescribed and had a relapse. He again visited the same eye-specialists without being encouraged, and when he came back to me, he was very much discouraged. I believe that he would have returned sooner had not the other ophthalmologists influenced him against the relaxation treatment.

After studying these and other cases, I believe that **the cause of detachment of the retina is usually some form of mental strain.** It is gratifying to have proved that when this strain is relieved, the detachment of the retina disappears and the eye becomes normal.

## Stories from the Clinic

### Mind Strain

By EMILY C. LIERMAN

THERE are many causes of mind strain and hundreds of people suffer from its effects without realizing it. People who have difficult problems to solve are subject to mind strain. Business and financial worries also cause mind strain, which is usually accompanied by eyestrain. If these people are taught the proper way to relax, mind and eyestrain can soon be relieved. It is not easy to relax. Osteopathy helps some people, but the difficulty lies in being able to continue the relaxation methods after the doctor has completed his treatment. This is true of the Bates Method of relaxation. Most patients who have been treated for eyestrain leave the office after their first treatment, feeling entirely relieved of pain, fatigue, and mind strain, and with decided improvement in their vision, either for the distance, the near point or both. Such patients obtain normal vision permanently by carrying out at home the advice given by the doctor.

Many patients ask why their pain or other discomforts return after treatment. The answer is obvious. It is caused by a patient not continuing the practice or by trying too hard while practicing. We are very apt to forget that which is most essential for obtaining better eyesight;—relaxation, rest of mind and body. Always remember that the eye is at rest only when it is moving. Dr. Bates emphasizes this fact, because patients so often forget. When the mind is under a strain, it is difficult to solve a problem or to think clearly.

A well known business man from the West, called to see Dr. Bates not long ago. He had been warned that Dr. Bates was not sincere nor scientific. The man was too busy to experiment with new ideas in eye treatment, so he went to Europe hoping to find a doctor there who could cure his eyestrain and the intense pains in his head. Opticians in Europe did their utmost to relieve him. When specialists in England failed to help him, he tried Germany, France, Switzerland and Italy. Had his search only carried him to Spain, he might have found Dr. Ruiz Arnau of Madrid, who is now there introducing Dr. Bates' method into schools, and to those medical doctors who desire to learn a better way of obtaining perfect vision, than the use of eyeglasses. Dr. Arnau became interested in the Bates Method some years ago when he himself was suffering with continual headaches and other discomforts caused by mind and eyestrain. He came from San Juan, Porto Rico, leaving a good practice to seek the only Doctor who could help him. Dr. Arnau has shown his appreciation for what Dr. Bates has done for him by writing a book entitled, "El Uso Natural de la Vision," which he dedicated to Dr. Bates.

Many other doctors, who were seemingly incurable, have come to us and were cured. They in turn help their patients, so that eyeglasses can be discarded, or not become necessary.

The Westerner came back to America feeling very much discouraged, and with no hope of being cured. In a skeptical frame of mind, he came to Dr. Bates, as a last resort. After one treatment, in which he was entirely relieved of pain, he placed himself in Dr. Bates' care and in less than two weeks of daily treatment, was able to read letters, newspapers, and book type without the aid of eyeglasses. Many patients have visited Dr. Bates, through his recommendation, and his letters to Dr. Bates are full of gratitude for the cure of his mind and eyestrain.

When patients learn how to do their work, without effort or strain, regardless of the nature of the work, mind, memory, and, most of all, their imagination is improved.

During the summer months of this year, I cured a woman with a terrific amount of mind strain. She obtained no relief until she realized that making an effort to see, in reading, sewing, or doing other things, prevented a cure. "Take things easily," is only a short sentence of three words, but I repeated that sentence to her, seventy times seven, before she realized its great significance. I gave her a treatment daily for some weeks and when she left for her home, many miles from New York, she said she felt like a new woman, and would always be grateful for the results I had helped her to obtain. She now reads her books without the aid of eyeglasses, which she had worn constantly for more than twenty years. Palming, the long swing of her body, while reading the test

card, one letter at a time, helped. Constantly reminding her to blink, was most necessary.

Mind strain causes many things. It destroys the finest nature and many an innocent human being, and often drives people far away from pleasant surroundings, killing quicker than any electric storm.

**One can strain so much that the eyeball will become as hard as stone, and the pain unbearable.** When this condition becomes more or less permanent, it may be **glaucoma**. This is an organic disease which sometimes causes blindness overnight. I have described a case of glaucoma in my book, "Stories From The Clinic," in which a dear old lady seventy-nine years of age, had absolute glaucoma in one eye, with no perception of light. When I first began treating her, I did not realize that I could ever bring back any sight at all in that eye. Before she left the clinic, at her first treatment, she was able to distinguish some of the large letters of the test card, as it was held close to her face. Within five months' time, she had normal vision in that eye.

It is not always easy to treat the severe cases. When a patient has been under a strain for a length of time, it is sometimes difficult to relieve the strain permanently, in a short time. Patients vary in their response to treatment. While some obtain permanent relief in a few visits, others find it necessary to place themselves under treatment for a longer period.

## Dry Heat and Sun

By A. P. SCHULTZ, M.D.

ON March 25th I was taken with an attack of irido-keratitis. The onset was very sudden, while diving. All laboratory tests were negative. X-ray examinations and clinical examinations likewise. The tuberculin test was not tried. I consider it worthless, it is positive in too many people, whatever their state of health, and in my case would have been utterly useless as all the symptoms of a positive tuberculin test developed by omitting atophan for one day. After two months treatment, and after many consultations the conditions were worse than before. The diet all along was of the simplest antacid kind. Atophan alone gave relief, and that only for the time being. The instillation of one half percent of atropin solution was intolerable, dionin impossible. After taking atophan almost continuously for five weeks, I decided to discontinue it. It should not be taken continuously for longer than five or six days. On May 23rd I took instead of it 80 grains of sodium salicylate. Pain, redness, lachrymation, photophobia, increased. On May 24th I took forty grains of sodium salicylate and twenty-five grains of aspirin; the pain decreased a little. All other symptoms were worse. On May 25th all symptoms were much worse. I added sixteen capsules of colchi-sal to the other drugs. The hot fomentations I continued. There was no relief. During the night the pain was terrible. Hot applications were unbearable. I had to go back to atophan, 15 grains gave relief for an hour. I took fifteen grains more of atophan and a little later one half grain of codeine. The pain was better, but all other symptoms were as severe as before. This medication could not go on. I tried hot baths and hot compresses again; they were intolerable. Steaming the eye was unbearable. Tension of the eyeball remained normal.

On May 26th the eye was terribly inflamed, the color of a dark red cherry. Iris and pupil were indistinguishable, the whole being one equal gray. Sight almost gone. I could count fingers if I moved them in a good light and if less than one foot away. To have something crawl over the eye separating the individual from the rest of humankind is one of the most terrible experiences a man can have.

I thought of the electric heater with the copper reflector. The thought proved an inspiration, a Godsend. I had the diffused hot light fall on forehead, temple and eyelid for one and one half to two hours, and what relief!! It was phenomenal, truly miraculous!! The thermometer held in front of the eye registered 138 degrees. The heat burned the skin, the eyebrows and the eyelashes, but I could feel the eye improve. In less than two hours the pain was gone. This was about 9 p. m. on May 26th. On May 27th in the morning all the symptoms were better and I decided to give the hot light application a thorough trial as a curative measure. I had that heat pour on the parts from 10 a. m. to 12 noon, and from 1 p. m. to 5:30 p. m. The results were truly wonderful, the photophobia was all gone, so was the pain and the lachrymation, and the redness was fifty per cent less. The treatment was an ordeal, and frequently I had to increase the distance from the heater. A man who is in danger of losing an eye can stand much more than he thinks. On May 28th I repeated this hot light radiation treatment from 4:30 to 10 a. m., when I was completely exhausted from heat and perspiration, too weak to stand but the eye wonderfully improved, very little redness left and sight also improved. I used this method for about one hour in the morning and about one hour at night for about a month.

What caused the good result? It was not the heat alone, for hot fomentations had been used for months without effect. For about two months a hot pack had covered the eye day and night without good effect. I wrote to the Bureau of Standards, Washington, and received this information: "The copper reflector emits about **1% of visible radiation and 99% infrared rays**. Some of the rays of **short wave length** will penetrate deep into the interior of the eyeball. Most of the rays penetrate only 0.01 to 0.5 mm. into the eye."

About one month after the end of the inflammatory process a thick scar persisted which prevented vision; everything beyond six feet was a gray wall into which men, automobiles, houses, everything disappeared. How to get rid of the scar was the problem. The instillation of dionin and of theosinamin proved irritating and had to be stopped. The internal use of potassium iodide caused skin eruptions and other symptoms of iodism and also had to be stopped. I used the following:—The very restricted antacid diet was continued, consisting of vegetables (usually raw) and fruits, many lemons (one lemon to a glass of water) oranges, grapefruits, raw sauerkraut. Every now and then a day on fruits and water only. I have reasons for believing that increased alkalinity of the blood helps to dissolve scars. From August 23rd, 1925 to September 6th, 1925 the fast was complete except for water. It did some good. Exercise helps to overcome the results of inflammations of joints, why not in the eye? I exercised the eye by rolling it in various directions, rolling it under the closed eyelid added gentle massage of the cornea. I used the alternating bath. This works well to improve the circulation in people suffering from cold feet. There is no reason why it should not work equally well on the other end of the anatomy. The alternating bath consists in putting the part in hot water for a few minutes and then in cold water, alternating six or eight times. I did this two or three times a day. It did some good, the opacity was less but still marked.

In June, 1926, I wanted to play handball and found that I could see the swiftly moving ball intermittently only. I thought that the scar prevented the left pupil from contracting and dilating in harmony with the right pupil and that the mind suppressed the confused image completely. I decided to use the sun. **I looked straight into the sun with the left eye, then put the hand over the eye (darkness) and then read the smallest print that the eye could make out, looked into the sun again, etc. This worked wonders, the scar contracted and the opacity became thinner from day to day, today little is left of it.** Days on which there was no sunshine, and there were many, I used the electric heater. **The sun cured the opacity after every other factor had failed.** Something else happened. My eyes were myopic. Left eye 8½ diopters, Right eye 9.50 diopters. I had worn these eyeglasses since 1921. They began to trouble me some days for ten minutes only, on other days for hours. The refraction changed several times

on the same day. One examination revealed for the left eye, the treated eye, myopia of 4/50 diopters, for the right eye myopia of 8 diopter. Presbyopia was suggested. But vision at the near point was very good, much improved in fact. I looked up the subject, but found no explanation until I found Dr. Bates' wonderful book. On October 13th Dr. Bates gave me the first treatment, and in a few days I had flashes of normal sight, that is, I recognized the 10 lines of the Snellen test card at ten feet,—the first time in my life that I can remember. These periods are increasing in frequency and in duration, so that I have reason to believe that I shall be free of the myopia in a short time. **At the same time the sun treatment, aided by the treatment for the myopia: palming, swaying, swinging and reading of small print, is diminishing the opacity quickly.**

I do not advise placing the eyes near a electric heater as this man did.

I think if he had tried only natural full spectrum sunlight, sunning and the other Bates methods he described he would have had the same cure, maybe quicker.

Dr. Bates recommends to his patients, Ruth Loeblich, who has received instruction from him for two years in the Cure of Imperfect Sight by Treatment Without Glasses, and assists in the Clinic, conducted by Emily C. Lierman.

Miss Loeblich treats patients at the following addresses: 457 East 9th Street, Brooklyn, N. Y. Tel. Windsor 5655, and No. 60 West 49th Street, Apt. 4, N. Y. C.

### Cornea Scar Cure

Sunlight, Palming, Sway, Long Swing, Fine Print, Shifting, Blink, Central Fixation, Memory and Imagination, Relaxation, Abdominal Breathing, Movement.

## Questions and Answers

Q—Should one practice with fine print by holding it where it can be seen best or at the normal distance.

A—Hold the print at the distance from your eyes at which you see best. Remember not to look directly at the letters.

Modern Bates teachers state: to look directly at the letters (central fixation). Shift to see the letters clear: Move the eyes along the sentence. Avoid staring, squinting. Occasionally take a break, stop reading and then: look at, shift on the white spaces between the sentences, relax, daydream something pleasant, look to the distance. Return to the print when the eyes, mind are relaxed. Looking at the white spaces is not necessary to improve the vision and is not needed after the vision improves.

Q—Is age a factor in the cure of imperfect sight without glasses?

A—Age is not a factor. I have cured hundreds of patients past sixty.

Q—What method is best to relieve the tension in the back of the neck?

A—The variable swing. This is described in the September, 1926, number of the Better Eyesight Magazine. See Demonstrate article Paragraph 2. Infinity Swing/Figure Eight, Long Swing, Massage, Shifting, Tracing with the Nosefeather. See last pages this book.

Q—Is the swing apt to cause nystagmus?

A—No, the swing relieves strain, whereas nystagmus is caused by eyestrain.

Q—When taking Dr. Bates' treatment, could one wear glasses for a few hours each day for close work?

A—No, each time you put on your glasses, your progress is retarded.

Q—What causes the lids of the eyes to itch and sometimes become scaly?

A—This is due to strain. Practice relaxation methods all day long,—shifting, blinking and central fixation. Get as much sun treatment as possible.

Q—What causes my vision to improve for a day or two, and then relapse?

A—This is caused by lack of practice and by straining your eyes. When the vision is good, you are relaxed.

Q—In palming, should one close the eyes tightly?

A—No, easily, lazily and naturally at all times.

Q—Why is my vision worse on a rainy or cloudy day than in broad daylight?

A—Because you strain to see on a dark day.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

DECEMBER, 1926

### Demonstrate

**THAT** it requires an effort or a strain to produce imperfect sight.

Look at the notch at the top of the big "C" of the Snellen test card at fifteen feet. Keep your eyes fixed on the notch. Make an effort to see it and increase that effort as much as you possibly can. Notice that it is difficult to keep your eyes and mind fixed on that one point. Notice also that it is tiresome and makes your eyes pain. If you keep it up long enough, your head begins to ache and all the nerves of your body are strained.

If you look at some of the letters on the lower lines which are much smaller than the big "C", they may appear so blurred that you are not able to distinguish them. Trying to see these small letters blurs them still more.

Now hold the test card in your hand about one foot from your eyes. The big "C" is seen plainly and without any effort. Try to see the top and the bottom of the big "C" perfectly black at the same time. Notice that the "C" becomes blurred and the strain which blurs it also gives much discomfort.

From this evidence, we can conclude that perfect sight comes easily, without any effort or strain, while, imperfect sight is always produced by a strain or an effort to see.

### Astigmatism

By W. H. BATES, M.D.

MANY people who have astigmatism often talk about it in a boastful way as though it were a mark of distinction. This is not so strange, considering the fact that so many eye doctors claim that astigmatism does more harm to the eyes and nerves than any other condition. They tell their patients that in order to prevent serious eye diseases, glasses should be worn constantly. Such patients, accordingly, become much worried and are in constant fear of serious eye trouble developing, and probable blindness resulting. It is true that the glasses prescribed may give temporary relief; but no patient under my observation was ever cured or benefited very much by glasses.

### Definitions

The normal eye is spherical in shape and all the meridians are of the same curvature. The curvature of the cornea is like that of a segment of a sphere; but when astigmatism is present, it is said to be lop-sided; that is, one principal meridian of the curvature is more convex than the meridian at right angles to it. With an instrument called the ophthalmometer, it is possible to measure all the meridians of the curvature of the cornea.

Astigmatism may be simple hypermetropic, simple myopic, compound hypermetropic, compound myopic, mixed or irregular.

In **Simple Hypermetropic Astigmatism**, one principal meridian of the cornea has a normal curvature, while the meridian at right angles to it is flatter than all the other meridians.

In **Simple Myopic Astigmatism** one principal meridian of the cornea has a normal curvature, while the meridian at right angles to it is more convex than all the other meridians.

In **Compound Hypermetropic Astigmatism**, the two principal meridians are flatter than the meridians of the normal eye, one being flatter than the other.

In **Compound Myopic Astigmatism**, the two principal meridians are more convex than a normal meridian, one being more convex than the other.

In **Mixed Astigmatism**, one of the principal meridians is flatter than a meridian of the normal eye, while the other principal meridian is more convex than a meridian of the normal eye.

In **Irregular Astigmatism**, the meridians of the curvature of the cornea are so malformed that no glasses can correct the astigmatism.

### Occurrence

Astigmatism is the most common defect of the human eye. Most people with astigmatism have had it since birth. In some cases, it may increase, while in other cases it may become less or entirely disappear.

Nine-tenths of the cases of **astigmatism** are due to **imperfect curvature** of two or more meridians of the **cornea**. The other cases of astigmatism are due to imperfect curvature of the **lens**, or less frequently to a malformation of the **eyeball**.

## Symptoms

When a high degree of astigmatism is present, the vision is appreciably lowered. Usually when vertical lines are regarded, they may appear more distinct than horizontal lines, or the reverse may be true. It was found that so many patients with astigmatism failed to see vertical lines as well as horizontal lines, or had trouble in seeing oblique lines, that a card, called the clock-faced card, was designed with lines at various angles. At one time it was believed that astigmatism could be diagnosed when the patient was able to see horizontal lines on this card better than the vertical lines or vice versa. Some patients with astigmatism could see distinctly the line pointing to five o'clock, while the line at right angles to it could not be seen so well. With increased experience, however, it was found that some patients with astigmatism could see horizontal and vertical lines equally well. On the other hand, patients with normal vision have complained that they did not always see vertical or horizontal lines equally well.

A man, sixty years of age, was found to have unusually good vision without any symptoms of astigmatism; but when he regarded a number of vertical, horizontal, and oblique lines, his vision immediately became very imperfect with a production of six diopters of astigmatism. When he closed his eyes and rested them, his vision soon became normal and the astigmatism disappeared.

The standard, old clock face card (astigmatism wheel) is not an effective test for astigmatism and often results in unnecessary eyeglass prescriptions with astigmatism correction. This occurs because the eye doctor tells the patient to use incorrect eye function to see the clock: The patient is told to keep the eyes immobile, looking at only the dot in the center of the clock while at the same time, also trying to see all the lines around the clock in the peripheral field perfectly clear. This prevents central fixation and shifting, two major normal eye functions necessary for clear vision. It also causes temporary strain, blur and astigmatism during the test. Other conditions of the standard card astigmatism test also produce incorrect results.

The resulting unnecessary astigmatism eyeglass prescription causes, increases astigmatism resulting in more vision impairment.

A Natural Eyesight Improvement astigmatism wheel allows the person to look directly at and shift on the lines, one at a time to test for and remove astigmatism. The standard old card is also seen clear when it is used correct with shifting and central fixation.

Astigmatism can cause lines on the wheel to appear blurry, light, double, wavy...

Horizontal line blurry, light.

Vertical line double.

Diagonal lines blurry, light, double.

Normal - Every line the eyes look at is dark black, single, clear.

If a line is unclear - shift on it. Blink. Imagine it dark black and clear white shifting on the line with the eyes open, then in imagination with eyes closed, then open again. Practice on the line with both eyes, one eye at a time, both eyes again. Practice at close, middle, far distances.

Natural Eyesight Improvement Astigmatism Wheel

Standard, old Astigmatism wheel

Shift on the lines.  
Left and right - 3 to 3, 3 to 9  
Up and down - 12 to 6, 6 to 12  
Diagonally - 8 to 2, 2 to 6, 10 to 4, 4 to 10, 5 to 11, 7 to 1  
Shift, trace on one line in any direction, center to left or right, up, down, diagonally, and back to center.  
Move the eyes/center of the visual field along the lines and remember, imagine, see the lines dark black and perfectly clear.  
Central fixation: see one small part of a line clearest at a time in the center of the visual field and move the eyes/center of the visual field continually, easy, relaxed along the line from part to part.  
Blink, breathe slow, subconsciously, relax.

Astigmatism can appear and disappear in the normal eye without discomfort, notice. Doctors state that the eye/cornea can change shape temporarily due to temporary occasional eye muscle tension, stress, neck tension, sinus congestion, diet resulting in slight astigmatism.

## Cause

The cause of astigmatism is always associated with an effort or a strain. In all cases the stare can be demonstrated. An imperfect memory requires an effort or a strain and always produces astigmatism. An imperfect imagination also requires an effort or strain and always produces astigmatism. A mental strain of any kind always causes astigmatism. In the normal eye, astigmatism can be produced with a very slight amount of strain or effort to see. In those cases, however, where a great effort is made for a length of time, the astigmatism becomes very much increased, and may be more or less permanent. Irregular astigmatism is caused by the contraction of scar tissue, either from ulcerations of the cornea or from an incised wound.

## Treatment

Some years ago, I published an article in the Archives of Ophthalmology with the title, "A New Operation for the Cure of Astigmatism—A Preliminary Report." In this article, I described an operation in which the more convex meridian of the cornea was incised at right angles to its curvature, but not penetrating into the anterior chamber. The scar produced by the cut of the knife usually healed very promptly, and the traction of the scar tissue flattened the curvature of this principal meridian. A number of cases were reported with good results. It was not very long, however, before I had some unsuccessful experiences in which, for some reason or other, the operation failed. The theory was so good that I expected the facts to verify it. I became disappointed with my operation and did not investigate the facts any further after the first six months. A year or two later, my operation was performed by some one in England, and a report of some interesting cases that were apparently cured was published in an English Medical journal. Other articles were published in medical journals, confirming my earlier claims and giving me due credit.

I no longer believe that an operation of any kind should be performed, because all forms of astigmatism can be demonstrated to be always temporary. Astigmatism is not organic; it is always functional, even when scar tissue is associated with it.

## Scar Tissue

It is very interesting to observe cases of astigmatism in which scar tissue of the cornea is a complication. Scar tissue, as is well known, is composed largely of new connective tissue. With the aid of the memory and the imagination, this connective tissue sometimes disappears in a very short time. When the memory is perfect for some letter, color, or object, the scar tissue disappears. When the imagination is perfect for a letter or other object, the scar tissue disappears. Imagination or memory of perfect sight is a cure for astigmatism.

## Conical Cornea

The most serious effect of astigmatism is to produce conical cornea. In this disease, the front part of the eyeball becomes more conical in shape, and after some years the apex of the cone becomes ulcerated: This ulcer becomes steadily worse with an increase of the astigmatism. Not only is the vision progressively lowered, but the patient may also suffer from severe pain. There is no operation which has been generally accepted which is satisfactory in correcting conical cornea, nor has any treatment heretofore practiced been curative or even beneficial.

The treatment in my experience which has yielded the best results is the practice of the variable swing. The patient holds the forefinger of one hand about six inches in front and to one side of the eyes. When he moves his head a short distance from side to side, the finger appears to move in the direction opposite to the movement of the head and eyes.

While practicing the variable swing, the patient is directed to regard one known letter of the Snellen test card at ten or fifteen feet, and imagine it as well as he can with his eyes open for a few seconds. The eyes are quickly closed while the patient remembers the same letter more perfectly than it was seen. He then opens his eyes and imagines the known letter on the card, as well as he can for a few seconds. The patient alternately remembers the known letter perfectly with the eyes closed and imagines it with the eyes open for a few seconds, until he becomes able to imagine he sees the known letter nearly as well with his eyes open as he can remember it with his eyes closed. By this method, the patient can improve his vision for each known or unknown letter of the Snellen test card. It is remarkable how promptly the conical cornea subsides when the variable swing is practiced in this way. Some patients have obtained normal vision in a much shorter time than one would expect.

## Case Reports

Recently a man, aged sixty years, was treated by me for the relief of eye troubles, caused by one-quarter of a diopter of **astigmatism**. He suffered intensely from strong light and complained of **floating specks**. He was not able to read fine print with or without glasses for any length of time without pain and fatigue. It seemed very strange that he should suffer so much from so low a degree of astigmatism. His distant vision was almost normal, while his ability to read was only slightly impaired by the pain. When his astigmatism was corrected by treatment, his vision, with each eye, for distance improved until it became normal, and the floating specks disappeared. After practicing the swing and improving his vision for the Snellen test card, the fatigue which he had felt when working and reading was also lessened. He no longer suffered from discomfort in the strong light of the sun, after he had received the sun treatment with the sun-glass.

### Conical Cornea Treatment

Variable Swing

1 E

Eyes open - Shift on a known letter on the eyechart and imagine it clear.

2 E

Eyes closed. Shift on the letter in the mind and remember, imagine it clear.

3 E

Eyes open - Shift on the letter and imagine it clear. Repeat 1,2,3.

Practice until the letter is imagined perfectly, equally clear with the eyes open and when closed and the letter is seen perfect, dark black and clear on the eyechart.

Eyechart 10-15 feet.

## Hypermetropic Astigmatism

About a month ago, a fourteen year old girl came to me for treatment. She had about three diopters of hypermetropic astigmatism in each eye. The vision of each eye was one-half of the normal. After practicing rest and the short away of her body for an hour or longer, her vision became almost normal without glasses.

Without any treatment, she read the fine print imperfectly at twelve inches. She was directed to close her eyes and to imagine the spaces between the lines to be as white as snow, white starch, whitewash or a white handkerchief. With her eyes open and moving her head a short distance from side to side, she became able to imagine the white spaces between the lines to be more perfectly white. By alternating, her imagination of the white spaces increased, until she became able to read diamond type at six inches or less, without any fatigue or discomfort. Her ability to read had been improved by her imagination. When her symptoms were relieved by this treatment, it was found with the aid of the retinoscope that the astigmatism had disappeared.

## Compound Myopic Astigmatism

Another patient was a girl, aged fifteen. The vision of the right eye was one-third of the normal, while that of the left eye was one-fifth of the normal. She was wearing glasses for the correction of compound myopic astigmatism, in which the astigmatism in each eye was less than one diopter. With the aid of pacing, swinging, and the use of her imagination, her vision became normal in each eye and the astigmatism disappeared.

This patient had but one treatment and obtained a quick cure, which is very unusual.

## Simple Hypermetropic Astigmatism

On June 1, 1924, a man, thirty years old, became a patient. The vision of his right eye was 10/70, while that of the left eye was 3/200. For the correction of astigmatism, he was wearing a convex 5.00 D.C. in the right eye and convex 5.50 D.C. in the left eye. His glasses were not satisfactory, and he suffered from double vision. He could not remember mental pictures or read fine print.

After palming, swaying, flashing and blinking, his vision was temporarily improved and the double vision disappeared. He obtained a considerable amount of rest from the drifting swing. The universal swing was also a great benefit. His ability to read was improved by having him imagine the white spaces between the lines of black letters to be whiter than they really were. It helped when he imagined that he was painting the white spaces with white paint, alternately with his eyes closed and with his eyes open. His vision was very much improved by the imagination of the white centers of most letters to be whiter than they really are.

His visits were irregular. Nevertheless, on October 22nd, the vision of the right eye had improved to the normal, while the vision of the left eye had improved to 15/70. With the aid of the retinoscope, it was demonstrated that the astigmatism of the right eye had entirely disappeared, while that of the left eye was very much reduced.

The histories of these cases indicate the possibilities of relieving all degrees of astigmatism without the use of glasses.

Emily C. Lierman and W. H. Bates, M.D., take this opportunity of wishing you a Merry Christmas and a Happy New Year.

They desire to thank you for your interest and hope that the Better Eyesight Magazine will be improved upon in the New Year.

## Stories from the Clinic

### The Christmas Party

By EMILY C. LIERMAN

THE same Christmas spirit prevailed at our clinic last year as it had in other years. This time our tree was more beautiful than ever. Dr. Bates helped in selecting it, and it was so large and beautiful, that everybody at the party marveled at its splendor. Generous contributions from our friends made it possible to purchase appropriate gifts for our clinic family. Those who have had clinical experience will agree that the poor are not always willing to accept charity. They are more willing to give, and sometimes sacrifice a great deal. Even before many of these patients are cured of their own imperfect sight, much of their time is spent in helping others. They obtain test cards and other material and give them to those who need help for their eyes, but who cannot attend our clinic, because it is held during their working hours. Considering this attitude, it is necessary to use tact in extending our Christmas cheer.

Last Christmas, little Margaret Mary, who was under treatment for squint, held the interest of every child and mother present. Even the private patients forgot their eye troubles to watch this happy little girl. The dolls were placed on a table near the tree with its many colored lights. Each little girl was asked to choose her doll, as they were all different. There was one doll in the group that was not so pretty as the others, and I feared very much that she would not find a mother. I had a mental picture of her being left behind while some other doll or toy was chosen. It was Margaret Mary's turn to choose, and she held her breath as she stood before the dolls. She looked at each one in turn, and then back to the plain little doll. For a few minutes she stood still. Suddenly her arms went out to the plain doll and she held it tightly to her. I shall always remember her expression as she chose it. It was one of mother love and I am sure everyone recognized it as I did.

Among the children was a boy, aged ten, whose father was a foreigner and could not speak very good English. This little chap had been coming to the clinic for some time before Christmas and was being treated for hysterical blindness. A note from his teacher explained why she had sent him to me. The school nurse said that he was mentally deficient. He knew the alphabet and could read numbers, but could not spell a word. The nurse and teacher were under the impression that glasses might help the condition of his mind, as well as his sight. His name was difficult for me to remember, so I called him Bobby. Bobby always kept his head lowered and his eyes almost closed while I talked to him. Until his third visit, his answers to my questions were unintelligible. His father was always ready to reply to the questions I asked Bobby, but I could not understand him either.

After many failures in trying to interest Bobby in the test cards with various letters and numbers, I turned to a large geographical globe in my room and began to turn it, at first slowly, and then more quickly. He watched me, raised his head and opened his eyes

wide. I observed him closely as his staring eyes, scarcely blinking, followed the turning of this strange thing that fascinated him. His facial expression changed and I knew that he was interested. Slowly he came toward the globe and gave it a turn or two himself. I was hoping he would do that, but his father apparently did not want him to touch it. He rose quickly from his chair and in a rough voice, ordered Bobby to be seated. Bobby's eyes again lowered and his head dropped. I had discovered one cause of Bobby's trouble. His father's harsh manner reacted upon the child's eyes. During my many years of clinical work, I have seen other fathers like him and, I am sorry to say, some mothers, too. Poor Bobby! I could not say much, but I would like to have requested the father to wait outside during the treatment, but he would not have understood.

Later Bobby made progress with the use of the Pot Hooks Card, which had the letter E of different sizes, pointing in various directions. After the third visit, Bobby's sight continued to improve and he learned to pronounce words and read them correctly.

At the Christmas party, Bobby's keen interest in the large Christmas tree and its many lights was a joy to see. There were games and toys for the boys, according to their ages, and silver stick pins and cuff buttons for the young men. Bobby was standing near the toys and games, and was asked to choose his gift. He disappointed us all by choosing a pair of cuff buttons. He smiled with gratitude and we knew that he was pleased.

Bobby did not return for any more treatment, but his mind had improved with the improvement of his eyesight, and he no longer lowered his head and eyes when spoken to. I felt that something real had been accomplished.

Among others at our Christmas party, was a man who had been a brakeman on a train for some years. When his vision became so poor that glasses no longer helped him, and the loss of his eyesight endangered the lives of others, he was discharged by the company for which he worked. His family of five were in want and he could not find steady work.

He had come for his first treatment, two months before Christmas. He had progressive myopia, and even with glasses he could not see clearly beyond six feet. His vision was 10/100 with each eye. Toward the end of March, less than six months later, he was again working on the freight trains without glasses, and with almost normal vision. On his last visit, his sight had improved to 10/10 and his nervous condition was benefited at the same time.

At the Christmas party, he received a little gift for each member of his family and enough oranges and candy for all. As he left, he had tears of joy in his eyes.

## The Cross-Eyed Fairy

By GEORGE M. GUILD

FAIRIES are magnetic, attractive and pretty. They are usually free from care and trouble, and spend most of their time in dancing, singing and playing with nice little boys and sweet lovable girls. Their eyes are usually bright, sparkling, loving and kind. It is very unusual for a fairy to have any eye trouble. One warm summer night while I was asleep, some one whispered in my ear: "Have you seen the cross-eyed fairy?" Of all the fairies I had seen and I had seen many thousands, not one could I remember who was cross-eyed.

The whisper was so faint that it did not wake me, but it was sufficient to startle me and make me very restless. I imagined that I saw a fairy with cross-eyes and not only was one eye crooked, but her nose was also turned out of line. I tried many times, but it was not possible for me to get hold of the nose in order to twist it back to where it belonged. The fairy ran away, dodging behind bushes, trees, and flowers, just like a will-o-the-wisp. I searched everywhere in my dreams for the little sprite, but in vain.

When I woke up, I decided to visit the fairies and, if possible, have a talk with the cross-eyed fairy that evening. There was a full moon so bright that I knew that the dell where the fairies assembled would be almost as bright as though it were daylight. Soon after I arrived where the fairies were gathered, I sought the queen and found her. When she saw me, she asked me if I had seen the cross-eyed fairy. I told her that nothing could interest me more than to meet her. "Would it make you love the little fairy less," she asked, "if you saw her with cross-eyes?"

I answered, "No, please let me see her."

"Perhaps you would try to cure her by an operation?"

"Oh, no," I replied, "I would never do that!"

"Do you think glasses would help her?" she asked.

The thought of a pretty fairy wearing large heavy glasses was repugnant to me. I told the queen that I had never known of anybody with cross-eyes who was cured by wearing glasses. I had seen many cured, but they had all recovered without the use of glasses and needed no operation.

The queen then led me to a part of the forest where the cross-eyed fairy had sought refuge from the pitying eyes of her friends. I had noticed that most cross-eyed people were extremely unhappy, and I had always tried to cure them and make them happy. The queen of the fairies remembered that I had always done something to relieve fairies who were unhappy. I had found that fairies suffered just as much as anybody else, and needed some help as well as mortals. The queen then took me to the cross-eyed fairy who lay on a soft bed of moss with her head and face turned away from the fairies who were curious. When I arrived, she was crying and sobbing continuously, suffering as only a sensitive fairy can suffer. Many of the other fairies tried in vain to comfort her. We were all overwhelmed with a great pity, but it was difficult to know what to do.

"How did she become cross-eyed?" I asked.

One fairy answered that she caught it from Mary, a four year old child who had visited her. I asked where Mary lived and went to see her. I found her living in a cottage on the shore of a lake. Her father and mother and brothers and sisters were all very nervous, so I persuaded them all to dance and play. **Mary enjoyed being thrown around in a circle fast and then faster, until her feet could not touch the floor.** One of the older boys held her hands in his, while he played this new game, of swinging her feet clear of the floor. When she practiced this swing, it made her laugh. She enjoyed it so much that she begged everybody to swing her.

The Swing in its many different forms cures squint, cross/wandering eyes.

**While swinging I told her to look upwards and her eyes became perfectly straight, temporarily.** By practicing the swing more continuously her eyes remained straight for a longer time. She said that her eyes were not tired any more and she felt rested. I swung with her for hours, and then her father, mother and others relieved me and swung her feet from the floor, until late in the afternoon.

The Swing

Swing the child around by the hands clockwise, counter-clockwise, clockwise. Child looks up into parents eyes and also sees oppositional movement of objects in the visual field moving by in the opposite direction the body is spinning toward. Improves clarity of vision, gets the eyes relaxed, moving normal, straightens crossed, wandering eyes, activates, integrates left and right brain hemispheres, relaxes body, mind, eyes in a active, dynamic, fun state of mind.

Before the moonlight appeared, I took Mary to visit the cross-eyed fairy. There she was, still lying on her face, and crying bitterly. Mary told her how she had been cured by the swing. The cross-eyed fairy stopped crying and listened attentively. All the other fairies listened, too, and then began to swing her until her feet were flying around without touching the ground. They all enjoyed this new game and were very gay. The fairy with the cross-eyes enjoyed it most of all and kept begging for more. She said that her eyes became straighter and straighter until they were almost cured. She said that it made her eyes feel better and she felt relaxed all over.

All the fairies became so happy over this, that they led me to a nearby hamlet where dozens of boys and girls had cross-eyes. At once the queen caught hold of a cross-eyed boy and swung him in a circle until his eyes became straight. I did the same to others, until all were temporarily cured. Then a wonderful thing happened. The cross-eyed fairy swung another child, the last one of all, until the eyes became straight, and then they were all completely cured, including the cross-eyed fairy. I visited them the next and many days later and found all of them completely and permanently cured.

Years later I returned to the little hamlet and found no more children with cross-eyes and everybody there was very happy.

## ANNOUNCEMENT

Miss Katherine Hayes, of the Central Fixation Publishing Company, will be pleased to improve cases of imperfect sight by treatment without glasses at 303 West 122nd Street, New York City, Telephone—Cathedral 3450.

## Questions and Answers

Q—What causes my vision to become blurred upon sudden confusion or when I have a number of activities coming at once?

A—The fact that your vision becomes blurred at such times is proof of your eccentric fixation. Do not try to see or do several things at once. Practice central fixation, seeing the part regarded best and other parts not so clearly, all day long.

Organize, make a list, then do one project at a time. Learn dexterity: use of left and right hands, feet for tasks.

Q—If bad eyesight is caused by some physical ailment, will your methods help?

A—Yes, relaxation is always a benefit, not only to the eyes, but to all the nerves of the body.

Q—My daughter, aged ten, is practicing your method for the cure of cross-eyes. Would it help to cover her good eye with a shield, which is easy for her and keeps the left eye straight for a certain period of time, besides making it work? It helped her so much when she wore glasses, that I thought it might help her without them in the same way.

A—It is first necessary to improve to normal the vision of both eyes, when used together. Then cover the good eye and practice improving the vision of the poor eye.

Q—I am sixty-five years old and, in addition to bifocals, I am wearing strong prism glasses for reading. These tire me and strain my eyes. Am I too old to be helped by your methods, and would the adjustment of my eyesight increase the dizzy attacks which I have had and which I dread most of all?

A—Age is not a factor in the cure of imperfect sight by my methods. Patients, eighty years and older, have become able to read fine print at six inches and have obtained normal sight for distance. Relaxation prevents dizziness and is beneficial to the entire system. (See December, 1925, number of "Better Eyesight" on **Dizziness**.)

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JANUARY, 1927

### Demonstrate

1. That perfect sight is not possible unless one imagines a letter to be moving, and that an effort to imagine a letter stationary always fails. Close your eyes and remember a small letter of the Snellen test card. Imagine that some one is moving the test card a short distance from side to side so that all the letters on the card appear to be moving with the movement of the card. Remember the small letter moving. You can remember it provided you imagine it is moving. Now try to stop this movement by staring at one part of the small letter and imagining that it is stationary. The letter soon becomes blurred.

2. That the circular swing prevents the stare and relieves pain and fatigue.

Hold the forefinger of one hand about six inches in front of one eye and a few inches to the outer side of the face. By moving the head and eyes in a circular or an elliptical orbit, notice that the finger appears to move in the direction opposite to the movement of the head and eyes. Now realize that the hand must move with the finger because the hand and finger are fastened together. When one moves, the other moves in the same direction, up, down, to the right or left. The same fact is true of the arm fastened to the wrist. When the finger moves, the hand, wrist and arm in turn, all move and in the same direction. Likewise when the finger moves, the shoulder moves with it and other parts of the body fastened directly or indirectly to the finger. You may soon become able to imagine the chair on which you are sitting to be fastened indirectly to the finger. When one moves, the other always moves in the same direction. When you become able to imagine all things, one at a time to be moving with the finger, i.e., the universal swing, the stare is prevented and pain and fatigue disappear. The memory, imagination and vision are also improved.

Distant objects will appear to move in the same direction the eyes, head, body move to.

## Hypermetropia

By W. H. BATES, M.D.

### Definition

**BY HYPERMETROPIA** is meant a shortening of the diameter of the eyeball so that images are focused behind the retina instead of in front of it as in myopia. The vision for distant objects may be imperfect. Some writers have defined the hypermetropic eye as a far-sighted eye, because near vision is usually imperfect, while distant vision is usually good. The myopic eye is called near-sighted, because the vision is usually good at a near point.

Round Eye.  
Light rays from distant objects focus on the retina.  
Clear distant vision.

Slightly lengthened eye.  
Light rays from close objects focus on the retina.  
Clear close vision.

Abnormal lengthened eye.  
Light rays from distant objects focus before the retina.  
Distant vision is unclear.  
When the eye is lengthened too much (as shown in the diagram), close vision is also unclear.

Abnormal shortened eye.  
Light rays from close objects focus behind the retina.  
Close vision is unclear.  
When the eye is shortened too much (as shown in the diagram), distant vision is also unclear.

### Occurrence

Hypermetropia occurs more frequently than any other form of imperfect sight. Some statistics have shown that about eighty per cent of all people have hypermetropia. Hypermetropia is acquired by persons who strain their eyes to see at the near point. After the removal of the lens, as in cataract extraction, a high degree of hypermetropia is produced. It is not unusual for people to acquire hypermetropia at the age of forty or fifty, when presbyopia is prevalent. With few exceptions, all persons fifty years of age have acquired hypermetropia, to such an extent that they are unable to read without glasses.

### Symptoms

Hypermetropia may cause much pain, headache, fatigue, and other nervous troubles. The vision at the near point is not so good in hypermetropia as in the normal eye, while the vision for distance is not impaired to the same extent. There are, however, a great many cases of far-sightedness, in which the vision for distance is much less than some cases of myopia. To classify cases of hypermetropia as being farsighted is not always correct. The hypermetropic eye is not always a farsighted eye.

If the shape of the eye is progressively impaired: too long  too short : light rays from close and distant objects focus incorrect before and/or beyond the retina resulting in unclear close and distant vision.

### Cause

Hypermetropia is usually a functional condition of the eye, i.e., it is caused by a mental strain. There are, however, cases of hypermetropia which occur after the removal of the lens, as in cataract extraction; but even in these cases, mental strain to see at the near point always increases the hypermetropia. In all forms of hypermetropia, relaxation at the near point lessens the hypermetropia, whatever the cause may be. Knowing that the cause is due to a mental strain at the near point, the successful treatment of all forms of hypermetropia is suggested.

### Treatment

All measures which prevent strain and promote relaxation are always beneficial. Hypermetropia responds to "strain" almost immediately. A strain at a near point always increases the amount of hypermetropia or produces it in the normal eye while a strain to see at a distance lessens hypermetropia and the vision may improve and continue to improve until myopia is produced, when the vision is lowered. When the lens is removed in the normal eye, the hypermetropia produced is still functional and curable.

The cure of hypermetropia is accomplished by lessening or correcting the strain to see at the near point. The correction of the distance strain is usually more readily accomplished. With perfect sight, there is no strain. The eyes are at rest. Any effort that is made to improve the vision is always wrong and never succeeds. When the vision is normal, the eyes are at rest.

Strain to see at the distance might cause the abnormal shortened eye shape (that causes far-sight/unclear close vision) to change to a round shape, then to the abnormally lengthened shape that causes unclear distant vision. If the shape is not lengthened too much, then, the eye will be in the slightly lengthened shape that is normal for clear close vision. Continued strain to see at the distance (and at any distance) will eventually cause increased abnormal eye shape and unclear vision at all distances.

A strain to see up close might cause the abnormally lengthened eye, that causes unclear distant vision to become more/closer to the round shape needed for clear distant vision, thus producing clear distant vision. This strain will also eventually lead to unclear vision at all distances.

Some people use eyeglasses for the wrong distance (Close vision, plus lenses for distant...) in an attempt to force the eye muscles to change the eyes shape and produce clear vision. This results in extreme eye muscle tension, malfunction, confusion,

strain in the brain, eyes, visual system, unclear vision at all distances and can cause cataracts and other eye problems.

Straining to see at any distance, and use of eyeglasses is unnatural.

Avoid eyeglasses. Do not strain the eyes at any distance.

Use relaxation, Bates Method and vision will become clear naturally.

## Imagination

Demonstrate that perfect sight is accomplished when the imagination is good, and that you see only what you imagine you see. Take a Snellen test card and hold it at a distance from your eyes at which your sight is fairly good. Look at the white center of the large "O" and compare the whiteness of the center of the "O" with the whiteness of the rest of the card. You may do it readily; but if not, use a screen, that is, a card with a small hole in it. With that card, cover over the black part of the letter "O", and note the white center of the letter which is exposed by the opening in the screen. Remove the screen and observe that there is a change in the appearance of the white, which appears to be a whiter white, when the black part of the letter is exposed. When the black part of the letter is covered with a screen, the center of the "O" is of the same whiteness as the rest of the card. It is, therefore, possible to demonstrate that you do not see the white center of the "O" whiter than the rest of the card, because you are seeing something that is not there. When you see something that is not there, you do not really see it, you only imagine it. The whiter you can imagine the center of the "O", the better becomes the vision for the letter "O", and when the vision of the letter "O" improves, the vision of all the letters on the card improves. The perfect imagination of the white center of the "O" means perfect imagination of the black, because you cannot imagine the white perfectly, without imagining the black perfectly. By practice you may become able to imagine the letter "O" much better than it really is, and when this is accomplished, you become able to actually see unknown letters.

## Test Card Practice

Practice with the Snellen test card at ten feet. Regard the known letter and imagine that you see it. Your imagination of the letter may be imperfect with your eyes open. Then close your eyes and the letter may be remembered more perfectly. Open your eyes for a second and imagine the known letter on the card at ten feet, close the eyes quickly and remember the known letter better for part of a minute. Then when the known letter, with the eyes closed, is remembered perfectly, open your eyes and imagine it on the card. By doing this alternately, the imagination of the known letter, with the eyes open, improves, until you become able to imagine you see the known letter clearly enough to tell what it is. If you become able to imagine you see the known letter quite clearly, you actually can see the unknown letters and read the whole line.

## Swinging

It is also beneficial while practicing this method to sway the body, head and eyes, a short distance from side to side, and imagine the card and the letters to be moving in the opposite direction. It may help you to imagine the card moving by regarding the background close to one vertical edge of the card. By swaying from side to side the edge of the card appears to move over the background. The shorter the movement of the body, head and eyes, the shorter is the movement of the card and the better is it remembered, imagined or seen. **The short swing is more beneficial than the long swing.** It is necessary to realize, however, that it doesn't require much of a strain to stop the short swing and blur the whole card. When the short swing stops, you should increase the swing or the swaying of the body from side to side, until the card can be again imagined to be moving. This combination of swaying, memory with the eyes closed, and imagination with the eyes open, is a cure for hypermetropia.

## Fine Print

When the vision for distance becomes nearly normal, the vision at the near point can then be improved to normal. Hold a card of fine print about ten inches from the eyes. Do not look directly at the letters. Imagine that where the bottom of the letters comes in contact with the white space between the lines, that the whiteness is increased, and with practice you can become able to imagine a thin, white line, which is below the letters and whiter than the rest of the white space. When this thin, white line is imagined white enough, the letters are imagined black enough to be read.

If you fail to imagine this thin, white line, with your eyes open you may be able to imagine it with your eyes closed. Then open your eyes and imagine it as well as you can. Close your eyes and remember or imagine the thin, white line whiter. Then bring the card up an inch or two closer and imagine the thin, white line as well with the eyes open as you can remember it with the eyes closed. By alternately remembering, with the eyes closed, the thin, white line quite perfectly at ten inches, it becomes possible to imagine it with the eyes open at nine inches or six inches, or even nearer, and to imagine it as well with the eyes open as with the eyes closed. When you become able to imagine the thin, white line as well at six inches with the eyes open, as you can remember it with the eyes closed, the hypermetropia is usually corrected. This treatment has cured hypermetropia of 16 D.S.

Sway left and right in front of a eyechart and distant objects and see. The Swing: the eyechart moves in the opposite direction the body, head, eyes move to. Distant objects appear to move in the same direction the body, head eyes move to. The eyechart moves over the background, distant objects. The chart and distant objects move against each other in opposite directions.

The Thin White Line also appears directly above, along the top of the sentence. The thin white line above and below sentences is the combined halos of the top and bottom of the letters in the sentences.

## Central Fixation

The following case illustrates the possibilities of the cure of hypermetropia by treatment without glasses.

Mr. George, aged thirty-five, was employed as an assistant in a library. His vision without glasses was only 5/200, with convex sixteen diopters his sight was improved to 20/50. A second pair of glasses, convex 20 diopters was required to enable him to see to read and do his work.

An operation had been performed some years previously for the removal of congenital cataract. This case was apparently one which was not curable. However, he was given relaxation treatment to find out how much benefit could be obtained.

After closing his eyes and resting them for half an hour, his vision without glasses improved to 20/200 which continued only for a very short time, a few seconds. He demonstrated that concentration, trying to see by an effort, always lowered his vision very quickly. Blinking frequently, or palming, i.e., covering his closed eyes with the palms of both hands, was restful and his sight improved temporarily. He became able to imagine one part best of a large letter, while the other parts of the letter were seen worse, i.e., central fixation. He demonstrated that the practice of central fixation was restful, easy, required no effort, and always helped his sight.

After he regarded a Snellen test card which was moved an inch or less from side to side, he became able by practice to imagine the small letters of a stationary Snellen card to be moving or swinging. With the help of this movement central fixation was demonstrated until his vision improved continuously to 20/40, a vision which was better than that with his strong glasses.

This unusually good result was an encouragement to attempt to improve his vision for reading. When tested with the fine print, diamond type, he demonstrated that with the card held at two feet he read no letters, but the white spaces between the lines of black letters could be imagined whiter than the rest of the card and without effort or strain. By practice, with his eyes closed his memory or imagination became better than with his eyes open. It was suggested that he keep his eyes closed for part of a minute while remembering the whiteness of snow and to imagine it with his eyes open for only a short time. By alternating, his imagination with his eyes open improved for the whiteness of the white spaces and for the blackness of the letters. His vision became better for the diamond type at six inches than at twelve inches.

## Stories from the Clinic

### The Swing

By EMILY C. LIERMAN

RECENTLY I had the pleasure of talking to a large gathering of people in Chicago who were interested in the Bates Method. I was very much impressed by the fact that there was not a corner or part of the large room that was not lighted. As I watched the people coming in, I noticed an air of cheerfulness about them which attracted me. The meeting was held in the office of Dr. Jean Clavier who is very successful in treating and curing patients by the Bates Method. A number of doctors mingled with patients and their friends in the audience. After the lecture, several important questions were asked which helped all of those present to better understand the Bates Method. It was not difficult to determine those in the audience who knew nothing about the Bates Method, and the benefits that could be derived from it, as they were wearing glasses and the more I talked, the more they stared at me. This staring was an unconscious act on the part of these people. I told them about the various ways in which patients could be relieved of their eye strain, and spoke of those who stare and the suffering it caused. I added that there were quite a number who were listening to me who forgot to blink their eyes. It was interesting to watch the blinking habit begin. I mentioned the fact that those who did not have trouble with their eyes, blinked unconsciously and irregularly all the time, except when they were asleep. It was surprising to me and to Dr. Edith T. Fisher and Miss Elisabet Hansen, both students who were also present, to note how few there were who continued to stare after I brought this fact to their notice.

There were several school teachers there who asked me questions which I enjoyed answering, not only for their benefit but also for the benefit of others whom I knew were skeptical by the expression on their faces.

One teacher asked: "Should I apply the swing to the class in general or instruct each pupil separately?"

I answered: "Have them all stand up and sway together with you. Be sure to have them blink their eyes as they sway."

## Benefits

**The body swing, which is so relaxing and helpful in relieving all strain of the body as well as of the eyes, is similar to the movement of the eyes themselves.** When the eye blinks, it also moves slightly from side to side, without effort or strain. Dr. Bates has proved that when the eye is at rest, it is moving. I have observed many people in great pain and have recognized the fact that they do not blink often enough. Not knowing that blinking is a good habit, they stare and make their condition worse. Staring

brings on more tension, therefore the pain becomes more intense. When the patient is reminded not to stare and is told to move the head slightly from side to side, even though he cannot move the rest of his body, he becomes relaxed and soon falls asleep. Moving the head from side to side on the pillow is in the nature of the swing. Many patients erroneously believe that they have to sway the whole body, in order to produce the relaxation necessary for the relief of eye strain. I believe that the swing is just as essential to the human body as it is to animals. **It is a good plan to watch the animals and learn a lesson from them.** The tiger and lion as well as other animals move most of the time while they are awake, and are, therefore, relaxed. The elephant sways his bulky body from side to side, because it rests him.

Children are often moving, active. They are in a state of deep or active 'dynamic' relaxation. Watch a child that has clear vision and you will get a free Natural Eyesight Improvement lesson. Notice the natural, easy way their eyes shift, see the 'moving twinkle' in their eyes. Don't let them know you are paying attention to their eyes because this will make them conscious of their eyes and that disrupts complete, natural eye shifting.

People who work in offices, department stores and other places of business can practice a short, easy swing of their bodies. The movement can be so slight as not to be conspicuous to others. It is always interesting to watch soldiers march and observe the sway of their bodies in unison with the rhythm of the music. A mother who is busy with her household duties is always grateful for the few minutes of rest and relaxation she obtains when rocking the baby. A baby in its cradle enjoys the movement of the rocking. If the heart stops beating, which is really a sway inside the body, the blood no longer has a chance to flow nor the pulse to beat. If the pendulum of the clock stops, the clock does not tell the time. In my opinion the swing is as great a blessing as the sunshine. Just as the benefit of the sun is lost, when wearing dark glasses or green shades, so is the swing lost by staring and straining.

A few months ago I treated and cured an interesting case of cataract. The patient, an old lady of sixty-eight, was a chronic invalid, most of her body being paralyzed. The sun treatment was a great relief to her and she liked to sit in her chair and have the sun shine on her closed eyelids, as she moved her head gently from side to side. While the light and heat of the sun was very beneficial and helped her to relax, the movement of her head, which I shall call the swing, gave her more relaxation than when she held her head still.

In the beginning of her treatment, I was not sure that I could cure her, because of her helplessness. Her crutches were constantly by her side and she needed help in order to go from one place to another. When I first saw her, she had just been told that an operation for the removal of the cataract would be necessary within a few months. I had great hope for an improvement in her condition because she enjoyed the sun treatment.

She had been skeptical that her eye trouble could be cured, but when I had her demonstrate the benefit of the swing as she sat in her chair, she had more confidence. She soon became more cheerful and there was a change not only in her eyes but in the expression of her face. Keeping up the sway of her body, moving from left to right as she sat in her chair, soon enabled her to hold one crutch with her crippled hand, place it under one arm and then take the other crutch, lean forward and place it under her other arm. Continued practice of the sway from her waist line up, enabled her to stand by herself and walk slowly with the aid of her crutches.

## Temperamental Strain

By L. M. STANTON, M.D.

NEW YORK

IT IS more natural to do things, both good and bad, unconsciously than consciously. Yet the road of progress is the reverse of this, and perhaps there is no felicity greater than that of translating unconsciousness into consciousness. Were a dog capable of it, he would be altogether human and no longer a dog.

Dr. Bates has well said—and what does he not say well?—that it is easier to strain unconsciously than consciously, and in order that we may deplore and so correct it, he advises us to prove it for ourselves. Ninety-nine per cent of those who suffer from poor vision are unaware that they strain in seeing and to convince them of it is not an easy task.

In spite of what has been written of strain and relaxation, we are still far from able to accomplish the one and avoid the other. In the matter of relaxation relating to vision, we practice the exercises given us in the Bates Method. That is, after learning what the eye does and does not do in order to see, we consciously imitate the unconscious behavior of the normal eye. As perfect sight is due to the absence of straining to see, we speak of these exercises as relaxing exercises. But on observing the vast difference in the results of these exercises upon our patients, we ask why this difference? Why is it that we get quick cures, rapid progress in one case and not in another, when apparently the exercises are practiced by both equally well? Dr. Bates repeatedly states, whether speaking of palming, shifting or swinging, that the practice can be done in the right or in the wrong way. In the successful case, the patient overcomes his strain, does the exercises easily, while in the unsuccessful case the element of strain remains—he does not do the exercises easily, his straining is yet to be realized, to be brought from unconsciousness to consciousness and dealt with. One who has only the strain in his eyes to contend with progresses rapidly, while one who has to detect the strain in himself has a harder task.

There are, then, two avenues of approach to normal sight, one through one's eyes and the other through one's self. The subject of strain in ones self, the temperamental strain, is vast and to do more than call attention to it in this article for Better Eyesight is impossible. I will, however, relate a few cases and some of my own experiences that may be suggestive. The experiences point to temperamental and the patients to simple visual strain.

On returning city-wards one evening, I had been reading comfortably on the train. When nearing the station, the train was delayed for some time by the home-going commuters. My eyes soon began to trouble me in an unaccountable way. I asked myself what was the matter, since they should have hurt me less in a quiet than in a jolting car. I found that while giving attention to what I was reading, I was at the same time anxious over the thought that I would be late for dinner, and that I had promised the cook an early dinner with an evening out; also that I had to visit a patient before returning home to my belated meal. In other words, I was mentally trying to give equal attention to several things at the same time. I was straining. It was as disrupting as trying to watch a Three Ring Circus. I could in a moment produce discomfort in my eyes not only by anxious thought, but by ungoverned, disorderly thinking.

On another occasion when reading a sign across the car there was one word I could not see in spite of blinking, swinging, etc. Suddenly the lights went out for an instant and when they came on again, I instantly saw the unseen word. The momentary rest to

my vision gave me the relaxation I had not otherwise obtained. I had been straining, but when the matter was taken out of my hands, the strain vanished and I saw.

A boy, ten years old, with slight convergent squint and a history of very marked squint when younger, could read 10/10 with the left eye, but only 10/70 with the right. The diamond type card he could not read at any distance with the right eye. With the left eye covered, the letters below 10/70 were seen gray with the right, the amblyopic eye, but when he imagined the letter swinging, which he very easily could do, he saw them black and soon could read the 10/30 line. It was the "easily" in his case that worked the miracle.

Another boy could not form a mental picture of his dog, but when he remembered one of the dog's legs, then another, when he thought of his back, then of his tail, and told me whether the latter was straight or curled, whether the color of the tail was the same as that of the back, his mental picture was much improved and so was his vision. The delight that this boy felt in his reconstructed dog was an important factor in his mental picture.

A man found that salmon fishing was an excellent mental picture, that he could hold it while looking at the card and could with great joy imagine the salmon jumping the rapids, thereby improving his eyesight. It was not only his imagination, but his emotion that had overcome his straining vision.

Now let us suppose three other cases with refractive errors paralleling the three just mentioned but in respect to temperament quite different. The first boy, we will say, cannot easily swing the letters, seeing them black, nor can he do anything with ease; the second boy's dog is not his comrade and he has no delight in a mental picture of him; the man cares nothing for nature and takes no pleasure in the leaping salmon. Here we have psychological problems, temperamental insufficiencies, to meet before the relaxation is established that cures the imperfect vision of these patients, and yet physical sight is no whit worse in the latter than in the former group.

If only we could give up, let go, let the thing be done for us, of how much strain would we rid ourselves! What a difference between trying to do a thing and doing it; between trying to see and seeing!

A boy shifts part to part on a mental picture of his dog, remembering, imagining the color, shape, size... of different parts of the dog. His memory of the dog becomes perfect and this relaxes his mind, eyes causing his vision to become clear.

A man enjoys salmon fishing. He can easily remember, imagine a perfect, clear mental picture of himself in color, motion, action, fishing for salmon, in a happy, positive state of mind while looking at the eye chart. His vision becomes clear.

## Questions and Answers

*All readers of this magazine are invited to send questions to the editor regarding any difficulties they may experience in using the various methods of treatment which it recommends. These will be answered as promptly as possible, in the magazine, if space permits, otherwise by mail. Kindly enclose a stamped, addressed envelope.*

Q—(1) Does working by artificial light affect the eyes? I work all day by electric light—am a book-keeper, and suffer a great deal from my eyes. I have been fitted with glasses, but cannot wear them. I feel that my eyes, instead of getting better from wearing them, get weaker.

(2) When I go out in the street after working I cannot stand the glare of the sun, and must keep my eyes half closed; otherwise I suffer a great deal of pain. Is it so because of my eyes being accustomed to the artificial light? It is not so on Sundays. (

3) Is it advisable to wear an eye-shade while working?—S. S.

A—(1) Working by artificial light should not injure the eyes. If it does, it is because you are straining them. The idea that the light is injurious may cause you to do this. If you think of it as quieting and beneficial, it may have the opposite effect. You are right in thinking that the glasses injure your eyes.

(2) The sun hurts your eyes when you go out on the street after working because you have been straining to see, not because you have been working by artificial light. Because you strain less on Sundays the sun does not hurt you.

(3) It is not advisable to wear an eye-shade while working.

Q—Can the blindness of squint be cured?—F. C. E.

A—Yes. It can be cured by the same methods that are employed to relieve strain in other cases of imperfect sight.

Q—Do you get as much benefit from gazing at the sun through a window as you would outdoors? I have read that it did no good to take a sunbath through glass.—E. C. H.

A—Yes. The strength of the sunlight is not appreciably modified by the glass.

Modern teachers state that; all glass, plastic, (windows, eyeglasses) block part of the sun's light spectrum resulting in unbalanced, unhealthy, partial spectrum light entering the eyes, brain, body. This impairs health, function of the eyes, brain, body, left and right brain hemispheres, sleep, hormones, other body systems and clarity of vision. Sunlight through a window is better than no light but pure full spectrum sunlight is best.

Q—1. When objects at a distance clear up they are double. Can you suggest a remedy for this double vision?

(2) When I open my eyes after palming my sight gradually clears, but an intense pain often comes in my eyes, so that they close.

The pain always starts with very clear vision. Is this eyestrain?—H. M.

A—1. If the objects are double when they clear up, relaxation is not complete, and the only remedy is to secure a greater degree of relaxation. This may be done in many ways. Use the method you have found most effective.

2. Yes. Your sight should be best when you open your eyes. If it clears up afterward, it is because you are making an effort to see. This produces the pain.

Seeing objects slightly double as vision is improving is common. The eye muscles are relaxing, returning to normal function, the eye, cornea, lens, is changing back to normal shape. The brain, left and right hemispheres are relaxing, returning to correct

function, integration. This can cause a slight temporary astigmatism/double effect. Keep shifting, central fixation, relaxation and the double effect will correct itself, double images will merge into one perfect clear image.

Q—1. How long should one palm and how often?

2. How young a patient can you treat by this method, and up to what age can you expect results? How would you handle a child that did not know its letters?

3. Is astigmatism curable by this method?

4. How long has the method been known?—J. H. W.

A—1. As often and as long as possible.

2. The age is immaterial. It is a matter of intelligence. Patients as old as eighty-two have been relieved. Children can be treated as soon as they are able to talk. Any small object can be used for eye training, and in the case of children who do not know their letters, kindergarten and Montessori equipment is often useful.

3. Yes.

4. Its evolution began thirty-five years ago. (1892) It has improved as experience was gained, and is still improving.

Bates Method is the natural, normal function of the eye: It has been in existence since the beginning of life, evolution of the eye in animals and humans.

## The Use Of The Sun Glass

In using the sun glass, it is well to accustom the eyes of the patient to the strong light by having him sit in the sun with his eyes closed, and at the same time he should slowly move his head from side to side, in order to avoid discomfort from the heat. Enough light shines through the eyelid to cause some people a great deal of discomfort at first, but after a few hours' exposure in this way, they become able to gradually open their eyes to some extent without squeezing the lids. When this stage is reached, one can focus, with the aid of the sun glass, the light on the dosed eyelids, which at first is very disagreeable. When the patient becomes able to open the eyes, he is directed to look as far down as possible, and in this way the pupil is protected by the lower lid. Then by gently lifting the upper lid, only the white part of the eye is exposed, while the sun's rays strike directly upon this part of the eyeball. The sun glass may then be used on the white part of the eye. Care should be taken to move the glass from side to side quickly. The length of time devoted to focusing the light on the white part of the eye is never longer than a few seconds. After such a treatment the patient almost immediately becomes able to open his eyes widely in the light.

The light through the sunglass is constantly moving and is used for a short time to prevent the sun from burning the eye.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

FEBRUARY, 1927

### Dizziness

**DIIZZINESS** is caused by eyestrain. Some people when standing on the roof of a house looking down, strain their eyes and become dizzy. Usually the dizziness is produced unconsciously. It can be produced consciously, however, by staring or straining to see some distant or near object.

Other people, when riding in an elevator, become dizzy and may suffer from attacks of imperfect sight with headache, nausea, and other nervous discomforts.

An old lady, aged sixty, told me that riding in an elevator always made her dizzy, and produced headaches with pain in her eyes and head. I tested her vision and found it to be normal both for distance and for reading without glasses. To obtain some facts, I rode in an elevator with her from the top to the bottom of the building and back again. I watched her eyes closely and found that she was staring at the floors which appeared to be moving opposite to the movement of the elevator.

I asked her why she stared at the floors which appeared to be moving by. She answered that she did not like to see them move, and was trying to correct the illusion by making an effort to keep them stationary. She said the harder she tried, the worse she felt. I suggested that she look at one part of the elevator and avoid looking at the floors. Her discomfort was at once relieved, and she was soon cured.

In all cases of dizziness, the stare or strain is always evident. When the stare or strain is relieved or prevented, dizziness does not occur. With advancing years attacks of dizziness and blindness occur more frequently than in younger individuals. All attacks of dizziness with blindness are quite readily cured by practicing the imagination of the swing, the memory of perfect eight, or by palming.

A stiff neck, limited neck movement, stiff, tense muscles, joints, limited body movement can cause different types of dizziness. Relaxation, movement, correct posture cures the dizziness.

Tense muscles in the shoulders, neck pull on the vertebrae, brain stem, nerves, blood vessels that travel to the eyes, ears., causing dizziness, even vertigo in extreme cases. Eye and ear muscle tension, unclear vision, floaters, spots... in the visual field, crossed/wandering eyes, ear ringing, headaches result. Misaligned vertebrae in the neck caused by a bad chiropractic treatment caused the author of this book vertigo, dizziness and a variety of vision problems. Conditions improved after new, good chiropractor treatment, physical therapy, better posture.

Incorrect posture, looking down at computer keys all day or pushing the head/neck forward..., holding the arms up or in other positions that lead to tension causes the muscles in the shoulders, back, neck, head, chest to become tense. Chronic muscle tension, strain, knots... in the muscles occur. Vertebrae can be pulled out of alignment in the neck. Another pair of muscles that cause dizziness, lowered vision is the muscle that attaches to the bone behind the ears, back/side of the neck and travels down to the front of the chest attaching to the collar bone. Massaging these and the other muscles helps to prevent tension.

## Squint (Strabismus, Crossed, Wandering Eyes) By W. H. BATES, M.D.

**SQUINT** is a condition of the eyes in which both eyes do not regard one point at the same time. It is very common, and more prevalent among children than adults. Many cases improve with advancing years, while others may become worse. Squint may occur at the same time with myopia, astigmatism, or hypermetropia, or with any disease of the inside of the eye.

### Different types of Squint - Strabismus - Crossed, Wandering Eyes.

One eye  
crossed in.

Both eyes  
crossed in.

One eye  
wanders  
out.

One eye  
wanders  
up.

One eye  
wanders out,  
other eye down.

Other variations of incorrect eye movement can occur and it can change, alternate. A person with squint can learn to move their eyes in any direction and to control, manipulate double images of a object (candle flame...) and this can teach them how to avoid the tension, strain that causes incorrect eye movement and to remove the Squint.

### Symptoms

In squint, one eye does not look in the same direction as the other. For example, the left eye may look straight at the Snellen test card with normal vision, while the right eye may turn in toward the nose, and have imperfect sight. The squint is variable in some cases. At times it may be less or disappear altogether, while at other times it may be more pronounced. In some cases of squint, the patient is conscious of the strain. When the eyes turn in, he may be conscious that his eyes are not straight. When the eyes are nearly straight, he is usually able to realize that the eyes are not so strained.

### Cause

The cause of squint in all cases is due to strain. **When the eyes are under one kind of strain, they may turn in, and with a different strain, they may turn out, or one eye may be higher than the other, all caused by strain.** The relief or cure of one kind of strain relieves or cures all forms of strain. Squint in any form is always benefited by rest.

### Various cures for crossed/wandering eyes

#### Rest

The best treatment for squint is mental rest. Many patients with squint suffer very much from eyestrain. By closing the eyes and resting them, or by palming for a few minutes or longer, about ten times a day, most of these cases are cured without other treatment.

#### Patch

In many cases, the squinting eye has imperfect sight. When the eyes are examined with the ophthalmoscope, no change can usually be discovered in the retina. Such cases have what is called "amblyopia ex anopsia." Some cases are **benefited by wearing a patch over the good eye, so that the patient is compelled to use the squinting eye for vision.** After several weeks or months, the vision of the squinting eye may become normal by constantly wearing a patch over the good eye. **Many cases of squint are cured in this way.**

Eyepatch

## Swinging

The strain, from which so many of these patients suffer, is benefited by the **swing**. Almost all squint cases can be taught to imagine, while the good eye is covered, that stationary objects are moving. In cases where the swing of stationary objects is not readily accomplished, any of the following methods may be effective:

Stand 10 feet or less in front of the Eyechart and look 5 feet to the right side of the card, then five feet to the left side. Repeat. Move the head/body with the eyes. Notice the chart moves in the opposite direction the eyes, head/body move to.

Shorten the movement: Look back and forth to the right and left side of the letter C. See the C move in the opposite direction.

Shorten the swing again: Shift to the left and right sides of the C (on the dots) closer and closer to the C and see a shorter, smaller oppositional movement.

Shift shorter, smaller shifts directly on the C and on small parts of the C and see small and tiny oppositional movement.

Shift left and right on the E and see it move opposite the shift of the eyes.

Practice on the C, E, any letters with both eyes and one eye at a time.

Stare at a point-the letter stops moving and blurs. Shift point to point-the letter moves and is clear.

Shift on memorized, known letters on a familiar eye chart (Example: letter E). Remember, imagine the E perfect, dark black, clear, the white spaces pure white and see the letter moving. When the memory of the letter is perfect, it is seen clear and other letters are clear.

When the patient regards the Snellen test card at fifteen feet or nearer, and looks a few inches to the right of the big "C", the letter is always to the left of where he is looking. When he looks a few inches or further to the left of the "C", it is always to the right of where he is looking. By alternately looking from right to left of the "C", he becomes able to imagine it to be moving in the opposite direction. By shortening the distance between the points regarded, the swing is also shortened. The patient is encouraged to practice this swing with the good eye covered. When the swing is practiced correctly, there is always a benefit to the vision and squint. Practice shifting left and right on the letter E.

1. The forefinger is held about six inches in front of the face, and a short distance to one side. By looking straight ahead and moving the head from side to side, the finger appears to move. This movement of the finger is greater than the movement of objects at the distance, but, by practice, patients become able to imagine not only the finger to be moving, but also distant objects as well.

2. The patient may stand about two feet to one side of a table on which an open book is placed. When he steps one or two paces forward, the book and the table appear to move backward. When he takes two or more steps backward, the table and the book appear to move forward.

3. The patient stands in front of a window and looks at the distant houses. By swaying his body from side to side, the window, the curtains, or the curtain cord may be imagined to be moving from side to side, in the opposite direction to the movement of his body, and the more distant objects appear to move in the same direction that he moves his head and eyes.

4. The patient stands ten feet or less from the Snellen test card and looks to the right side of the room, five feet or more from the card. When he looks to the right, the card is always to the left of where he is looking. When he looks to the left side of the room, the card is to the right of where he is looking. By alternately looking from one side of the card to the other, the patient becomes able to imagine that when he looks to the right, everything in the room moves to the left. When he looks to the left, everything in the room appears to move to the right. After some practice, he becomes able to imagine that the card is moving in the opposite direction to the movement of his eyes. This movement can be shortened by shortening the movement of the eyes from side to side.

(Oppositional movement)

5. When the patient regards the Snellen test card at fifteen feet or nearer, and looks a few inches to the right of the big "C", the letter is always to the left of where he is looking. When he looks a few inches or further to the left of the "C", it is always to the right of where he is looking. By alternately looking from right to left of the "C", he becomes able to imagine it to be moving in the opposite direction. By shortening the distance between the points regarded, the swing is also shortened. The patient is encouraged to practice this swing with the good eye covered. When the swing is practiced correctly, there is always a benefit to the vision and squint. Practice shifting left and right on the letter E.

The Variable Swing

Place the finger in front of the face. Move the head left and right and see the finger/hand move in the opposite direction. Oppositional Movement.

Face a open window with a curtain cord hanging in the center. Sway the body left and right. See the window/cord move in the opposite direction the body, head/eyes move to. See distant objects move in the same direction.

Walk forward

Book move backwards, past the person.

Stand beside the book stand. Walk forward and notice the book moves past the body, backwards in the opposite direction. Next: Stand in front of the book. Walk forward and see the book appear to move toward you. Walk backward and the book moves away from the body.

## Memory

Some patients are very much benefited by being encouraged to remember the letters on the Snellen test card perfectly, i.e., to remember the black part of the letter perfectly black and the white part perfectly white. When the memory is perfect, it is possible for the imagination to be perfect. This being true, the patient becomes able, by practice, to imagine he sees each and every letter of the Snellen test card, and to imagine them to be moving. The movement of the swing can be stopped by staring at one point of a large or small letter, with the result that the vision is always lowered and the squint becomes worse. When the patient becomes able to imagine known letters perfectly, he is soon able to imagine the letters of a strange card perfectly. **When the letters are imagined perfectly, they are seen perfectly. Practice with a familiar card, or with a card whose letters are remembered, is one of the best methods known for curing the imperfect sight of squint and the squint itself.**

## Central Fixation

Another satisfactory method is to have the patient practice central fixation, or seeing best where he is looking, and seeing worse where he is not looking. **In practicing central fixation, it is necessary for the patient to shift constantly and to blink frequently.** To teach a patient central fixation, his attention is called to the fact that when he looks at the top of the card, he can distinguish the large letters, but the letters on the bottom of the card cannot be distinguished. When he looks at the bottom of the card, he sees the small letters where he is looking, better than the large letters on the upper part of the card, where he is not looking.

## Eccentric Fixation

Some patients have what is called "eccentric fixation", which is the opposite of "central fixation." Such patients see best where they are not looking. Eccentric fixation can always be demonstrated to be present when the vision is imperfect, or when the squint is manifest. To cure eccentric fixation, it is necessary to demonstrate these facts, and by practicing with the small letters, the results are usually good. The patient is told to look at the first letter on the bottom (left) line of the Snellen test card, which may be read at ten feet or nearer, and have him note that the letters toward the right end of the line are blurred or not seen at all. By alternately shifting from the beginning of the line to the end of the line and back again, the vision is usually improved, because eccentric fixation is lessened by this practice. Sometimes, it is necessary for the instructor to stand behind the card and watch the eyes of the patient, who may look a foot or more away from the letter that he is requested to regard with the squinting eye, while the good eye is covered. He may look a foot above or a foot below, or at some point a foot or more away from the letter which he is asked to regard. The instructor is usually able to tell when the patient is not looking at the letter desired. The instructor directs the patient to look down when he sees that the patient is looking too far up. The patient is directed to look to the right, when it is observed that he is looking too far to the left, and by watching him closely, the eccentric fixation can be corrected to such an extent that the vision becomes normal and the squint disappears.

Persons that have cataracts, macula degeneration, extreme blur and other vision impairments develop the destructive habit of eccentric fixation: to use the peripheral field of the retina, peripheral field of vision to see a object. This increases eye muscle tension... vision impairment. Central fixation and shifting cures this incorrect eye function.

## Fixing Eye

A great deal has been said about the "fixing eye" in squint, i.e., the eye that looks straight. Sometimes the vision of the squinting eye may be very poor, and one would expect the patient to focus with the eye that has better vision. This is not always the case, because some patients with a high degree of myopia in the left eye will turn the right eye in and look straight with the left eye. These cases are very interesting, no two are exactly alike and one needs to study the individual case in order to obtain the best results.

## Imagination

There are some rare cases where the vision is perfect in each eye, and yet the patient will suffer from squint. One may have considerable difficulty in finding the method of treatment which will cure or relieve these cases. One of the best methods is to have the patient practice the imagination cure. The patient can look at a page of a book twenty feet away and not read any of the letters. If the letter "O" is the second letter of the fourth word and on the 10th line, the vision may not be good enough for the patient to recognize the letter, but he may become able to imagine it. If he imagines that the left side is straight, it makes him uncomfortable and the left side is not imagined perfectly black. If he imagines that the left side is curved, he feels comfortable and the left side appears clearer and blacker. By imagining each of the four sides of the letter "O" perfectly, the imagination of the letter is improved, but if one or more sides are imagined imperfectly, the patient is uncomfortable and the vision or the imagination of the "O" becomes imperfect. Some patients are able to imagine perfectly and are conscious when they imagine imperfectly.

In one case, a girl eleven years of age was able to look for half a minute at diamond type which was placed ten feet away, at a distance where the patient could not distinguish the letters. She then closed her eyes, palmed, and imagined correctly each letter that her mother designated. For example, her mother picked out the capital letter "M", the first letter of the fourth word on the 10th line. While palming with her eyes closed, the patient imagined the left side straight, the right side straight, the top open and the bottom open. I asked her if it could be an "H." She answered that it could, but that she could imagine an "M" better, which was correct. Some patients are able to use their imagination correctly and imagine small letters just as well as capital letters. In order to obtain perfect results, it is necessary that the eyes be perfectly relaxed, and when the eyes are relaxed, all the nerves of the body are also relaxed. Those cases of squint which become able to do this are soon cured.

**Imagination of crossed images** with the eyes closed is characteristic of divergent squint, i.e., squint with the eyes turned out. **The patient imagines the crossed images alternately with the eyes open and with the eyes closed.** When, by practice, the imagination becomes as good with the eyes open as with the eyes closed, the squint is usually corrected.

When a letter is imagined, remembered, 'guessed' correct, clear - it is seen clear.

## Double Vision

### (Effective Cures for Squint: Imagining, Controlling Double Images)

After (in the event that) the usual treatment of squint has failed, it is well to teach such cases to see double. When the right eye turns in toward the nose and the left eye is straight, the letter or other object seen by the left or normal eye, is seen straight ahead, while the image seen by the right or squinting eye, is suppressed by an effort and is not seen at all. To teach the patient to see with both eyes at the same time requires much time and patience. When double vision is obtained, the image seen by the right eye is to the right, while the image seen by the left eye is to the left. We say that the images are seen on the same side as the eye which sees them. With the eyes closed, the patient is taught to imagine a letter, object or a light to be double, each image imagined to be on the same side as the eye with which the patient imagines he sees it. With an effort, the two images may be made to separate to any desired extent. By repeatedly imagining the double images with the eyes closed, the patient becomes able, with the eyes open, to imagine the double images to be separated a few inches or less, a foot apart or further.

**Patients become able not only to imagine images with the eyes closed, apparently seen on the same side as the eye which imagines them, but also—and this suggests curative treatment—to imagine crossed images, that is, the right eye image is imagined to the left, while the left eye image is imagined to the right. With one or both eyes turned in, each of the double images is imagined on the same side as the eye which imagines it. When the images are crossed, the convergent squint is over corrected and the eyes turn out.**

All this can at first be accomplished more readily with the eyes closed than with them open. **When the patient controls the separation of the images with the eyes open as well as with the eyes closed, the squint is benefited.**

Person imagines, sees with the eyes closed and open a candle flame appearing double. Imagines the left eye sees the left flame and the right eye sees the right flame. He controls, changes the width, amount of space between the two flames. (The eyes can be crossed varying amounts when open to see this.)

He then, with the eyes closed: imagines the right eye's image is seen to the left, and the left eye's image is seen to the right.

Then, again with the eyes closed and open he imagines the right image is seen by the right eye and left image is seen by the left eye.

He then merges the two images into one clear image and imagines and sees one image.

This helps wandering, crossed eyes to work together to produce correct double images when the eyes are crossed and a single image with the eyes straight, working together correct.

Treatment may vary depending on condition; internal squint/crossed eye, divergent squint...

Imagining, seeing and controlling double images of a candle flame to correct squint.

Swing the child in a circle counter-clockwise, clockwise... to correct squint.

## Case Reports

### I.

A boy, two years of age, had developed squint in his right eye several months before I saw him. He was just beginning to walk. At his first visit, I took hold of his hands and swung him round and round, until his feet were off the floor, and had him look up toward the ceiling. While doing this, his eyes became straight. The father and mother also took turns in swinging the child, and when he looked up into their faces, his eyes were straight. Every day, one or more members of the family would swing the boy around for at least five minutes. A year afterwards, the squint had not returned. Swing the child around in a circle counter clockwise, clockwise, counter clockwise...

Practice reading the eyechart, fine print, shifting, central fixation on any objects, remembering, imagining objects clear...with the right, crossed eye. Left eye patched. Palming, Long Swing, Sway, see The Swing. Then, practice with the other eye and both eyes together for equally balanced, clear vision in the left and right eyes.

### II.

A girl, aged fourteen, had an internal squint of the right eye. The vision of this eye was very poor, and she was unable to count fingers at one foot from that eye. The vision of the left eye was normal. She was encouraged to **use her right eye by covering the left with a patch**. She did not like the patch, so the lenses were removed from their frame, and an opaque glass was placed in the frame for the left eye. The girl was very nervous and wearing the glass gave her continual trouble. Her playmates teased her so much that she deliberately dropped them in the snow. Her father talked to her and insisted that she wear the frame with the opaque glass all the time. When she realized that she must keep the good eye covered until she was cured, her vision immediately began to improve. In less than a week, she became able to read the ten line on the Snellen test card at twenty feet with each eye. She also became able to read fine print with the right eye, just as well as she could with the left. The realization that she would have to wear the glass until she was cured was an incentive for her to practice those methods which improved her sight. When she looked at the Snellen test card at one foot, and remembered that the large letter at the top was a "C", with the aid of her imagination, she became able to see the "C." When she closed her eyes and remembered a better "C", she was able, with her eyes open, to imagine it at a greater distance, three feet. In a short time, her vision improved to 20/200 by alternately remembering a better "C" with her eyes closed, and imagining it as well as she could with her eyes open in flashes. Palming was a help and improved her vision to 20/40. A few days later, her vision had improved to 20/20 with the aid of the swing.

## III.

A young woman, twenty-four years of age, called to see me about her left eye which was causing her more or less pain. The left eye became very much fatigued when she tried to read. Her vision in that eye was 20/40. Her right eye had no perception of light and was turned in. A great many doctors had told the patient that the blindness was hopeless, and that nothing could be done to improve the vision of the right eye.

I had the patient practice the usual relaxation exercises, swinging, palming, etc. The vision of the left eye improved very rapidly, and, much to my surprise, the vision of the right eye also improved. After two weeks, during which the patient had received about six treatments, the vision of both eyes became normal. The right eye which had had no perception of light was sensitive now to a light reflected from the ophthalmoscope into her pupil. The pupil of the right eye always contracted when the light was turned into either eye.

The squint disappeared and she was able to see the same object, with both eyes, at the same time.

## Stories from the Clinic

### Case Reports

By EMILY C. LIERMAN

BEFORE knowing about the Bates Method, I did not think it possible that a person of seventy or more years could see without the aid of eye-glasses. After practicing the Bates Method, I discarded the glasses, which I had worn for thirteen years, and I have had good sight ever since.

Dr. Lilian Wentworth, of San Diego, Cal., who is now taking a course in the Bates Method, has brought several interesting facts to my attention. Her grandfather discarded glasses at the age of seventy-five, because he could not see with them. Living in the country, it was difficult for him to be fitted with suitable glasses for reading or distant vision. After being without glasses for a few weeks, he would read large print to while away the time. He had in his possession a book of psalms which was printed in rather large type, and he read this print daily to amuse himself. He then started reading the head lines of newspapers. This was very thrilling to him and the knowledge that he could do without his glasses caused him to boast to his friends about it.

Dr. Wentworth believes that we would be much happier if all of us would find something to occupy our minds. She urged her mother to take up glove mending at the age of seventy-five and her mother soon became successful with the work.

At the same time, Dr. Wentworth's mother conceived the idea of leaving off her glasses. She thought that she might become able to see and read without them just as her father had done at that age. An oculist had told her ten years previously, that she had incipient cataract of both eyes and that, in time, she would undoubtedly be forced to have the cataract removed by an operation. From the time she began mending gloves until she died, at the age of eighty-two, she did not use glasses again.

An operation had not been necessary because the **cataract had either disappeared or become absorbed**. That which interests me most in her case, is the fact that in glove mending it is necessary to use the finest silk or cotton thread obtainable. It was necessary for Mrs. Wentworth to make very fine stitches in mending the gloves or she would have failed. At all times her work was satisfactorily done and she was highly praised by those who gave her their work to do. Although she did not use glasses while working or reading, she put them on from time to time to test her ability to see with them. She complained that they did not fit her. In order to test her vision, she tried several times to find someone who could fit her with glasses, but was unsuccessful. She was always informed that there was nothing wrong with her sight.

I told Dr. Wentworth that I believed her mother had actually **cured herself of cataract by doing this fine sewing**. It is generally believed that fine work causes eyestrain, but it proved a benefit to her sight. Dr. Wentworth's mother enjoyed doing this work in her old age, and enjoying it, did not strain her eyes. I believe she forgot all about her eyes while using a fine needle and in making fine stitches.

Fine sewing is like fine print. If one strains to read fine print, one always fails; so it is with fine sewing. The more effort one makes while reading or sewing, without the aid of glasses or even with glasses, the more trouble one has in seeing. People with whom I have come in contact, who have had trouble with their eyes when reading, sewing or doing any kind of work with their glasses, were always better off without them, even though their vision was not good.

One of my patients, a woman, aged sixty-five, had myopia and cataract. Her vision was 6/50 in both eyes, in other words, she read the letters on the fifty-foot line of a test card, at six feet. **Palming** seemed most difficult for her to do. Closing her eyes to rest them helped temporarily, but when asked to read the same line of letters that she had just read, after having her eyes closed for a few minutes, she was unable to see the letters clearly enough to read them. I then realized that I must use another method, so I tried shifting. I had her **stand with her feet about a foot apart and swing her body to the left, as she looked out of the window off in the distance, then back to the test card, looking only at one letter that I was pointing to and then swinging her body, as she looked out of the window again**. Her vision in both eyes improved to the forty line. Shifting quickly from the test card, thus avoiding the stare, helped her to see all the letters clearly on that line. As she was a nervous person, I did not have her keep up this exercise very long. **I decided to teach her to swing back and forth, first placing the right foot forward, and swinging her body toward the test card; then after a few moments of this, she was told to reverse the movement and put the left foot forward. In this way, while seeing things move in the opposite direction, she read the thirty line letters, but she did not see them continuously**.

She complained of being tired, so I placed her in a chair and gave her a foot stool to rest her feet, as I wanted to be sure that she was comfortable. Then I taught her the **thumb movement exercise, i.e., making a small round circle with the thumb on the tip of the fore-finger of her right hand**.

After she had practiced the thumb movement for a few minutes, I gave her some white thread and a needle with a large eye and asked her to thread it. I told her to imagine one of the letters of the test card perfectly black, as she held the needle and thread in

Sway, swing the body left and right in front of an open window and eyechart. When moving left: look out the window, shift on a distant object. When moving right: shift for a 'fraction of second' on a letter on the test card, then move left and look out the window again. Repeat. Prevents staring, strain, blur.

Move the thumb side to side 1/4 inch or, do the thumb on finger tip movement as described in previous chapters. Move the eyes with the thumb. Imagine stationary objects moving, 'the swing' when the eyes shift.

place. She failed to accomplish what I asked her to do. I found I could do nothing more for her at that time, so I instructed her to keep up the thumb movement whenever she read her test card or practiced any other part of the method.

At her next lesson, her vision was 10/30 with both eyes and she saw all the letters clearly. **Shifting and swinging helped.** She read some of the letters of the twenty line as she looked from the test card to a design on the floor, which she had previously remembered and described to me when her eyes were closed.

She was told to resume the thumb movement exercise and blink as she looked at the twenty line letters. By looking down in her lap at her black dress, then glancing at the test card while blinking, she read the whole of the twenty line letters, one letter after another without stopping.

At her third lesson, she became able in a few minutes time to thread a needle without any trouble. I placed her in the sun and had her move her head from side to side, allowing the warm sun to shine on her closed eyelids. In less than an hour's time, her vision had improved to 10/10 in flashes.

## Questions and Answers

*All readers of this magazine are invited to send questions to the editor regarding any difficulties they may experience in using the various methods of treatment which it recommends. These will be answered as promptly as possible, in the magazine, if space permits, otherwise by mail. Kindly enclose a stamped, addressed envelope.*

### THE USE OF THE SUN GLASS

In using the sun glass, it is well to accustom the eyes of the patient to the strong light by having him sit in the sun with his eyes closed, and at the same time he should slowly move his head from side to side, in order to avoid discomfort from the heat. Enough light shines through the eyelids to cause some people a great deal of discomfort at first, but after a few hours' exposure in this way, they become able gradually to open their eyes to some extent without squeezing the lids. When this stage is reached, one can focus, with the aid of the sun glass, the light on the closed eyelids, which at first is very disagreeable. When the patient becomes able to open the eyes, he is directed to look as far down as possible, and in this way the pupil is protected by the lower lid. Then by gently lifting the upper lid, only the white part of the eye is exposed, while the sun's rays strike directly upon this part of the eyeball. The sun glass may then be used on the white part of the eye. Care should be taken to move the glass from side to side quickly. The length of time devoted to focusing the light on the white part of the eye is never longer than a few seconds. After such a treatment the patient almost immediately becomes able to open his eyes widely in the light.

Most modern Natural Eyesight Improvement teachers do not apply this sunlight method. Ophthalmologist Bates cured many vision problems, eye diseases with this sunlight and sunglass treatment.

**memory and imagination. Palming** should help you a great deal.

Neck, eye muscle tension, incorrect posture, staring at close distances, especially with the head, neck bent down and/or pushed forward for a long time, sinus pressure, congestion cause sparks of light, floaters and unclear vision.

The Sun Glass treatment must be done a specific way by a professional Bates Method Ophthalmologist. Plain full spectrum sunlight without the sunglass can be equally beneficial.

Q—In practicing the universal swing, beginning with the finger, then the hand, the chair, and so on until one gets to the sky, ought one to hold continuously in mind each object added together with the sky, or just the sky moving with the finger?

A—Imagine only one thing at a time moving with your finger.

Q—In Mrs. Lierman's book, "Stories from the Clinic," page 16, suggestion 11, she says: "It is very important that you learn how to imagine stationary objects to be moving without moving your head or body." Is this to be accomplished by a slight conscious movement of the eyes or is it entirely mental?

A—This is not accomplished by a conscious movement of the eyes. It is imaginary and mental. Let the eyes move on their own, automatically.

Q—Will relaxation methods alone remove a blood clot from the vitreous humor?

A—Yes, provided the patient practices my methods correctly and faithfully.

Q—How is it possible to get sun treatment when there has been no sun for days?

A—I should advise you to purchase a 250 or 500 watt electric light and sit in front of it with your eyes closed. It would be well to use the sun swing at this time which is moving the head a short distance from side to side. See the Ques. and Ans. column in October No. of B. E.

Q—When you suggest new methods do you mean to discontinue with the old?

A—Not necessarily, all the methods I recommend have relaxation for their object. It is for the patient to determine which treatment is most beneficial and to continue its practice faithfully. Some patients tire easily when one thing is done continuously. For this reason several are suggested in order to vary the practice.

Q—I have been able to improve my vision in one eye but not in the other. Can you give me a reason for this?

A—This is caused by imperfect imagination. If you will practice my methods of memory, imagination, blinking and shifting, your other eye will also improve. I suggest that when both eyes together are improved to normal, you wear a patch over the good eye as often as possible and practice until your other eye is also improved to normal.

Q—I am told that I am losing my "central vision." Is it possible to regain what I have already lost or to forestall the loss of the remainder?

A—Yes, it is possible by faithful practice of my methods.

Q—What causes my eyes to flash violet sparks and splashes?

A—This is caused by a mental strain. Learn to relax and improve your

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MARCH, 1927

### Demonstrate

That memory and Imagination improve the vision.

- + Look at the large letter at the top of the card and note that it may be more or less blurred.
- + Close the eyes and remember or imagine the same letter perfectly.
- + Then open both eyes and imagine it as well as you can.
- + In a second or less, close your eyes and remember the letter perfectly.
- + When this is accomplished open the eyes and imagine it as well as you can.
- + Close them quickly after a second or less.
- + Practice the slow, short, easy swing and alternately remember the large letter with the eyes closed for part of a minute or longer, and then open the eyes and imagine it as well as you can.
- + When done properly, you will be able to improve your vision of the large letter until it becomes quite perfect.
- + Then practice in the same way with the first letter of the second line.

Open - 'Flash' shift on the letter for a second or less, 'fraction of a second'.

Closed - Shift on the letter in the imagination, part of a minute, 10-30 seconds.

Open - 'Flash' shift on the letter for a second or less, 'fraction of a second'. Repeat.

+ Improve your imagination of the first letter of the second line in flashes, until it improves sufficiently for you to recognize the next letter without looking at it.

+ Improve the sight of the first letter of each line by alternately remembering it with the eyes closed for part of a minute and then flashing it (looking at/shifting on it) for just a moment, a second or less. You should be told what the first letter of each line is. With your eyes closed remember it as perfectly as you can. Then open your eyes and test your imagination for the letter for a very short time, one second or even less. Keep your eyes closed for at least a part of a minute, while remembering the known letter.

The flashes of the known letter with the eyes open become more frequent and last longer, until you become able to see, not only the known letter, but other unknown letters on the same line.

### Blinking and Shifting

By W. H. BATES, M.D.

**BY BLINKING** is meant the opening and closing of the eyes more or less rapidly. The normal eye with normal vision blinks almost continuously. Sometimes the upper lid just covers the pupil while in other cases both lids may be completely closed. With the aid of the moving picture camera it has been demonstrated that one may blink five times in one second without being conscious of it.

When an effort is made to stop blinking, whether successful or not, the vision is always lowered. When the eyes are permitted to blink regularly, easily, continuously, the vision is usually benefited. The camera also shows that the lower lids move up with a strong contraction of the muscle.

In many cases of normal vision, especially in those cases which are even better than the average normal vision, blinking is sometimes practiced with incredible rapidity, and on other occasions the eyes may blink infrequently, perhaps once in ten or fifteen seconds. The blinking of the normal eye varies or is different from the blinking of the eye with imperfect sight. The blinking of the eye with imperfect sight is usually very irregular and jerky and is accompanied by a manifest strain of the muscles of the eyelids. With imperfect sight an effort is always being made to hold the eye stationary and to stop the blinking.

**If the eyes are allowed to shift and to blink, the vision improves.**

Blinking is fundamental and very important, because one cannot shift frequently or continuously with improvement in the vision, unless the eyes blink often. To keep the eyes open without blinking requires an effort, a stare or strain, the patient becomes unable to shift easily or rapidly, and the vision always becomes imperfect.

The best way to rest the eyes is to close them while many things in turn are remembered or imagined. Blinking is a rapid method of resting the eyes and can be practiced unconsciously all day long, regardless of what one may be doing.

It is interesting to observe some people's eyes when they are **asleep**. One may note that the **eyelids are blinking**, which prevents the eyes from staring or straining, although the patient is unconscious of his eyes.

It is a well known fact that when people are asleep the eyes are often under a terrific strain. The first thing in the morning, after such a patient opens the eyes, he may find that his sight is very imperfect. He may suffer from pain in the eyes, pain in the head or in other parts of the body, or from extreme fatigue, as if he had been awake and hard at work all night long. When first opening the eyes, the patient may experience a feeling of dizziness, after the eyes have been straining during sleep. It is not an easy matter to recommend successful methods of obtaining relaxation, to such patients so that instead of working hard during sleep, the eyes may be completely relaxed and rested.

In some cases, the patient may have fairly good vision when he first opens his eyes after a good sleep. However, such cases are uncommon.

When the normal eye has normal vision it is always at rest, shifting. (The eye is relaxed, at rest when it is in motion, shifting.) During sleep, however, with the aid of simultaneous retinoscopy it has usually been demonstrated that the eyes are straining, staring or making an effort to see. The unconscious blinking is nature's method of resting the eyes during sleep.

## "Shifting"

### (Directions - How to Shift)

When the normal eye has normal vision it is always shifting or moving from one point to another. This is true with the eyes open as well as with the eyes closed. The shifting with the eyes open may be from side to side, from above, downward, or in any other direction. The horizontal shifting is practiced more than the other forms of shifting. The eye is never stationary. When the vision is imperfect, the shifting is also imperfect and may be jerky. It may result in discomfort of the eyes, the head or in any other part of the body. The shift of the normal eye varies and is more or less irregular.

To know the proper way to shift the normal eye, in order that the vision may be continuously normal, it is well to demonstrate the wrong way. **When the shifting is practiced or the eyes move from point to point, the vision is usually benefited, provided one shifts slowly, easily and continuously.**

(The eye, brain will activate saccadic and other faster shifts automatically, on its own.)

Advise the patient to look directly at one point or one part of the smallest letter which can be distinguished. When he does this for a few seconds, he usually becomes able to feel that an effort is being made, and when the effort is continued or increased, much discomfort is felt and the vision always becomes imperfect. The patient is encouraged to prove that concentration does not last long, and that it is impossible for the eyes, memory or mind to see perfectly, remember perfectly, or imagine perfectly, when an effort is made to concentrate. When the eyes shift from one point to another, a feeling of relaxation soon follows and the vision improves.

When the eyes do not shift from point to point, it can always be demonstrated that the vision becomes worse and that the eyes, mind and all the nerves of the body are uncomfortable and may be conscious of an effort or strain.

To constantly stare at one point of a letter or other object is wrong, because it lowers the vision and causes discomfort to the eyes. Perfect sight is not possible and cannot be imagined continuously, unless the shifting is continuous. The movement of letters or words which can always be demonstrated in normal vision, depends upon the shifting.

When the eyes stare and do not move, or when an effort is made to imagine letters or other objects to be stationary, the shifting stops, and if things seen are imagined to be stationary without shifting, or an effort is made to stop the shifting, the vision always becomes imperfect.

With the eyes open, it is possible to shift from the first letter of a line, of the Snellen test card, at fifteen feet, to the end of the line and improve the sight. In most cases a known letter of the Snellen test card can be remembered more or less perfectly with the eyes closed, but only when the eyes or the mind shifts from one letter to another, or from one part of one letter to another part. The letter remembered can be **imagined or a mental picture of the letter obtained only by constant, slow, short, regular, continuously, easy shifting.** When the patient can remember or imagine letters or other objects perfectly with the eyes open, as well as with the eyes closed, the vision is always benefited. If shifting is not practiced the vision always becomes worse.

Many people with imperfect sight are not able to shift or move their eyes without an effort.

They complain that they lose their mental control because they are unable to shift easily or continuously. **Much better vision is obtained with a short movement or shift of the eyes than with a long shift.** (Shifting on small objects, parts of objects, fine print letter.)

It is necessary for those who have imperfect sight caused by a stare, a strain or an effort to see, to become able to shift in such a way as to benefit their vision. Keep the eyes closed for a large part of a minute and open them for a short time, a second or less. It takes time to stare, concentrate or make an effort to see. It is not possible to stare and lower the vision in a fraction of a second. Perfect sight is inconceivably quick. It is easy, regular and continuous. **When shifting is practiced rapidly, easily and continuously, the symptoms of imperfect sight and other symptoms caused by strain are relieved at once.**

Shifting can be practiced slowly or rapidly, as long as effort, strain is avoided. Relax, practice easy.

The general belief is that when we read we are looking at the letters. When one reads with perfect sight one does not look at the letters, but at the white spaces between the lines and imagines the white centers of the letters to be whiter than they really are. Look directly at a small letter of the fine print that can be read and concentrate your mind and eyes on one part of the letter. You soon feel an effort or strain and the vision is always lowered. If the vision was not lowered, you were unable to keep your attention fixed on the same part of a small letter for a continuous length of time.

Modern teachers state: use central fixation. When you want to read the letters: look directly at the letters, move the eyes along the letters.

Do not try to read by looking at/moving the eyes along the white spaces. This would be eccentric fixation, diffusion; looking at two things at the same time, central and peripheral field. Eccentric fixation, diffusion causes mental and visual strain, blur.

Shifting is very often practiced wrongly and the vision becomes lowered or no benefit is gained. To shift rapidly, look up for a moment and then look down quickly, rest the eyes for part of a minute; then repeat, look up and down quickly without paying much, if any attention to the sight. While looking down again, rest the eyes for part of a minute. Alternate until the shifting up and down can always be accomplished rapidly or rapidly enough to avoid testing the sight. When the eyes move up the test card or other stationary objects move down. When the eyes move down stationary objects move up or in the opposite direction to the movement of the shifting eyes.

Try shifting relaxed, continuously from point to point on a object and from object to object. Blink.

Normal sight cannot be demonstrated continuously unless the eyes are continuously shifting. The patient is usually unconscious that he is shifting rapidly when he believes that he can see one letter of the bottom line perfectly and all the time.

Many people have said that they can see a letter with normal vision at fifteen feet or further without moving their eyes, and without imagining the letter to be moving. In other cases where some people thought they could regard one letter with normal vision without shifting, it was found that while doing this the eyes, when observed at the near point, a few feet or further, could be seen to move very quickly, up, down, from side to side or in other directions. **The movement of the eyes was so rapid that it was not noticeable, unless the patient was observed very closely.**

Shift part to part on a letter and from letter to letter to remember, imagine and see letters clear.  
Long Shift:  
Shift 4 to R, R to 4.

Shift part to part (dot to dot) on the E to see it clear.

Short shift:  
Shift dot to dot on the E, then try on a fine print E, then on one fine print dot.

When the top of a large letter is regarded, that part may be seen best for a short time, while the rest of the letter is seen worse, i.e. central fixation. One cannot see with central fixation and have normal vision unless one is continuously shifting. When the bottom of the letter is regarded, it may be seen best, while all the rest of the letter is seen worse. By shifting alternately from the top to the bottom of the large letter, the vision is usually improved. At the same time, the uncomfortable feeling in the eyes or head is relieved and all pain is benefited.

One patient with very unusual vision read the bottom line marked "10" not only at ten feet but at a much greater distance. In a good light she claimed that she could see one letter of the "10" line at fifteen feet continuously without blinking and without shifting. Although she was not conscious of the fact she must have been blinking or shifting because the moving picture camera has always demonstrated that no one could see one letter of the Snellen test card continuously without **rapid blinking or shifting**.

It requires time for one's sight to become imperfect. The habit of staring or straining cannot be accomplished in a second. It takes a longer time to fail than it takes to succeed. Perfect sight can only be obtained quickly without effort or strain. **The cure of imperfect sight, then, is to stop all effort.** It is not accomplished by doing things; it can only come by the things that one stops doing.

Shift top and bottom, left and right, part to part in any direction on a letter, seeing one small part clearest at a time in the center of the visual field for relaxation, clear vision.

## Stories from the Clinic

### Four Boys and a Girl

By EMILY C. LIERMAN

DURING my many years of clinic work with children, I have found that boys are easier to treat and cure of imperfect sight than girls of the same age.

Robert, aged eight, was one of the first of a group of four to be tested with the Snellen test card. His mother had noticed, during the last year, that his left eye was beginning to turn in. The school nurse had also noticed this and had recommended glasses for him. Robert had refused to be fitted with them. He said if he were compelled to undergo an examination for glasses, and they were purchased he would refuse to wear them.

I knew before I started treating Robert that I would have no trouble in improving his sight, if it were necessary. I was doubtful about his having imperfect sight, because I had watched him as he moved about, before I began treating him. I did notice, however, that he had a habit of keeping his head more to one side, which caused an unnecessary, strain and prevented him from seeing with both eyes straight. I noticed that at intervals, he had a slight convergent squint of the left eye.

Robert read 10/10 with the test card with each eye separately. While he was reading the card, I had his mother sit where she could watch his eyes. He read the test card so fast that it was hard for his mother to keep up with him, to notice whether he had made a mistake in reading the letters or not. He read up to the twenty line of the test card with his eyes perfectly relaxed. Then, as he read from the twenty to the ten line of letters, he began to frown and stare. It was then that the eye turned in. His mother was quick to observe this and commented on it. I asked her if she could describe to me what he did after he had read the twenty line letters. She said she noticed that he frowned and that the eye turned in, but that was all. I asked Robert if he could tell me what he did that was wrong when he arrived at the twenty line letters. He did not know so I explained to him and his mother that he had not blinked once, until he had read the last letter of the card.

When Robert first began reading the card I noticed that he blinked only twice from the time he started with the large two hundred line letter until he arrived at the twenty line. I explained to both of them that this was not enough; that the normal eye blinks often, irregularly and in an easy way, and that it is done unconsciously by persons with normal sight. I explained how necessary it was for Robert to consciously blink often, all day long, no matter what he was doing.

I taught him to palm, asking him to tell me what he was most interested in. I meant his school work, but did not tell him so. Before I had an opportunity to say that I meant school work, Robert cried out: "I like to play best." It was evident from his mother's expression that she thought I would be displeased with his reply, but it is natural for boys to enjoy and to like their play most. I told Robert to imagine he was playing basketball in the gymnasium, which I knew was part of his school routine.

While he palmed, I asked him to remember how he held the basketball, then threw it in the air, and finally made the basket. He smiled as I described this to him. After he had removed his hands from his eyes, he was instructed to stand and sway, and by reading one letter at a time, blinking for each letter, he read the whole card without frowning and with both eyes straight. His mother said I had performed a miracle. I told her that the cure was only temporary, and that Robert would unconsciously stare again and the eye would, undoubtedly, turn in. This would happen at irregular times, from day to day, until Robert made it a habit to blink and shift, as the normal eye does.

The next time I saw Robert and his mother they informed me that I had made a mistake. Robert's eye did not turn in again, neither did he forget to blink regularly and often. His second test was better than the first one. I had him stand fifteen feet from a strange card, which he had not previously read. He read every letter of the card with each eye separately and with both eyes together, not forgetting to blink and shift, and at all times both eyes were straight. Just saying to Robert's mother that he would forget to blink and that the eye would, without a doubt turn in again, made him determined to remember to use his eyes right.

Two other boys of this same group are brothers. One is nine and the other twelve years of age. James, the younger of the two, is keener, but more nervous. He read the whole test card, 10/10, without a mistake. Having watched Robert during his test, he knew exactly what was required of him. It was amusing to see how serious James was during the whole procedure. I had explained previously to Robert that the elephant has intelligence enough to sway his body in order to obtain relaxation and prevent strain. I explained that the elephant must sense that standing still is not good for him because it makes him uncomfortable, therefore, he keeps moving. James was anything but graceful; he swayed like a little elephant in reality. Everyone in the room watching him laughed, but not a smile out of James. At first I thought he was going to cry, because he became so excited and nervous. I stood quite close to him, and directed him to hold my hands and sway with me. After swinging with me for a short time, he learned to swing by himself. He had to be reminded that blinking alone was not sufficient. James began his lesson by blinking but not looking away. He stared at every letter until I stopped him. After he realized that it was necessary to shift, I had very little else to do for him. Looking out of the window and then back at the card, seeing one letter at a time, swaying, in this way for each letter, his vision

improved to 15/10. His second test was even better. He stood twenty feet from a card that he had not seen. He read straight through it without a mistake, with each eye separately.

James' grandmother, who was with him noticed that his nervous twitching ceased. Before, he had not been able to sit still in his chair longer than five minutes at a time, but now he could sit quietly with a book in his hand and read in any kind of light, and not move until it was bed time.

Jack, James' brother, acted as though he were a grown-up man. He very readily stood ten feet from the card and read it through like a race horse, staring all the while he did so. He had either forgotten that it was wrong to stare, or did not realize that he was staring. After he had finished reading the card, I asked him if that was the way he read his books, or the blackboard at school. "Oh, Yes," said he, "I can read even faster than that." Jack evidently thought that speed was what counted in the test. He was waiting patiently for praise and looked very forlorn when I found fault with him. He soon realized that the way he read the card was not correct, and that he was under a tension and strain when reading so rapidly. For a half hour I impressed upon his mind that he must not look at more than one letter of the test card at a time without blinking and looking away, which means shifting from the card to a blank wall, or some other place where there are no letters. He asked me why it was necessary to look away from the card after seeing each letter. I told him that when he looked away from the card, after seeing each letter, he prevented any strain of his eyes by looking at something that was not hard to see. In other words, shifting is something the normal eye does all the time, only people with good eyes do not notice that the eyes shift because it is done unconsciously.

The next time I saw Jack, I had him stand twenty-five feet from a strange card, and he read it correctly by seeing one letter at a time and looking away. Later he read each line of the card backwards, not looking at the card, but shifting from one side of the card to the other. I asked him to read from one of his books that he had with him, and show me how he read so that I could guide him if he did not read it correctly. After each sentence or two, he would look on the opposite page and see a capital letter at the beginning of a sentence, blink and then proceed with his reading. He told me he could read this way, without any feeling of fatigue, if he blinked his eyes, which he usually remembered to do.

Harold, aged eleven, was the tallest and stockiest of the group. His eyelids were swollen and very red, but his vision for each eye was 10/10. He had a habit of keeping his eyes open for a long time without blinking at all. Blinking was one of the first things I encouraged him to do. I had him stand by himself, in a corner of the room, and told him not to remove his hands from his eyes until I told him to do so. He nervously wiggled about in his chair after sitting a minute or so. I suppose that five minutes of palming seemed like five hours to him. When a boy of his age has imperfect sight but is perfectly healthy otherwise, it is almost impossible to expect him to be still, even for so short a time. I wanted to see whether palming would relieve the redness of the eyelids and I was glad to see that there was less redness, after he stopped palming. I then had him stand twenty feet from a strange test card and he read the ten line with each eye separately. He whispered in my ear that he was just a little afraid that the other boys would get ahead of him. There was a little sun streaming in one of the windows of the room. He stood there and closed his eyes while I used a sun glass on his eyelids. At first he was a bit frightened for fear that I would harm him, but after I had focused the sun's rays through the glass on his hand, he was reassured. The sun was most beneficial to his eyelids, and the redness disappeared before he left. I feel that the **redness of his eyelids was not wholly from eye strain, but from eating much candy and other sweets**, which he confessed he was fond of. If Harold follows my advice, I am sure that the condition of his eyelids will be normal, the next time I see him.

Anne, a girl aged twelve, who has myopia was my next patient. She was harder to convince and much harder to treat than the entire group of boys. Having difficulty to see at the distance even with her glasses, and not being able to see the blackboard or other things distinctly caused her to be sullen. The child's eye strain kept her from being happy as most children of her age are. She was reluctant to leave her glasses off, after her first treatment as she felt she looked better with them. I asked her what difference it made whether she was better looking with or without her glasses as long as her eyesight improved with the treatment. I told her about the boys whom I had just helped, and that not one of them had thought of how they would look without their glasses. She then promised to practice. Before treatment, her vision with the test card was 10/70 with each eye separately. After she had palmed a while, then swayed as she stood ten feet from the card, her vision improved to 10/50.

On her second visit, Anne's attitude had changed. She said that only one day had she worn her glasses in school since her first treatment, and that she was getting along very well without them. She practiced every day, as I directed her and palmed for more than ten or fifteen minutes at a time, while someone read a favorite story to her. By having someone read to her, she was able to **improve her mental pictures with her eyes closed**, and her vision is now 10/10, by flashing one letter at a time. She is not entirely cured, but if she continues to keep up her enthusiasm to rival the boys who did so well at the start, I feel sure that Anne will soon be cured.

## Case Reports

The following are case reports sent in by one of Dr. Bates' representatives, Miss Elisabet Hanson, of 1504 Capitol Bldg., Chicago, Illinois.

Dear Dr. Bates:

It has been so interesting to watch the unfolding of a recent case, pronounced hopeless by ophthalmologists, that I am writing about it.

Dr. M. L. Cleveland, Palm Beach, Florida, came to Chicago, July 9, 1926, having been told that she had glaucoma in one eye, would be blind in three months, and more than that, the eye would have to be moved in the faint hope of saving the other.

Her vision with glasses was 10/15 minus. Without glasses both eyes 10/100 minus, right 10/75 minus and left 10/100 minus. When she had done the long swing until she was fully relaxed, she palmed, listening to happy memories of snowy mountains, plains, forests, skies, etc. After half an hour of this, she was asked to open her eyes and look at the test card, which she read to 10/50. You can easily imagine that enthusiasm had full sway. Handing me her glasses, she said she was through with them. It being a sunny day, I gave her the sun treatment for a short while with the burning glass, and taught her the easy sun swing. This she said was delightfully soothing.

July 10th, the following day, her vision had improved to 10/40. There was a good reason for this. Dr. Cleveland has a wonderful imagination, and quickly saw how to use it. We began with the flashing lesson, that is, with the perfect memory of a known letter with closed eyes, she was able to flash every letter on the 10/30 line. Then I gave her a diamond print card and noticed

that she tried to read it and did not blink at all.

For relaxation, I explained the value of blinking and imagining white spaces on the card swinging.

Our lessons were interrupted for a while—Dr. Cleveland had to attend a Convention out West, but having already gained perfect confidence in the Bates system of Better Eyesight, she knew she was on the right track, and kept on with her exercises. When we met again, August 23rd, her vision had improved to 10/15 minus. Looking into the eye with the retinoscope, I saw that the dark shadow had disappeared almost entirely and the pupil, that had been abnormal, was now nearly normal in size. Moreover the hardness of the eyeball and terrible pain were gone. Continuing our lessons (thirteen in all) until she had to return to Florida, her progress was wonderful. She was ingenious, used each lesson in a way that best suited her case, and between lessons practiced in the house, on the porch, and in the park. In the latter she was able to read the ten line at twenty-five feet, and when she left Chicago she had perfect far vision and almost perfect near vision.

#### Blindness reversed

At this time Mrs. W., an elderly lady, was brought to me. She had been **blind for sixteen years**. The ophthalmologists called it obstruction of the optic nerve. She had only perception of light—the right eye being a little better than the left.

We began the treatment by practicing the long swing and palming. Then after imagining the big C, she discerned it on the chart at about six inches distance, as something dark and round. After palming again, she was able to get the two letters on the next line as two moving black spots. I ended this lesson by teaching the sun swing with closed eyelids. The next time she came, she told me she had swung the sun and palmed many times a day. We began our lesson with the sun glass treatment; palmed and swung the sun with closed eyes; more palming and to her surprise, she saw, with the card at one foot instead of six inches away, the big C and the smaller R B easily, and the still smaller letters down to the 20 line, as spots. Corrections had to be made: when she became very interested, she narrowed her eyes in an effort to see more. As this was evidence of an attempt to see through strain, the habit had to be curbed at once.

After more palming and the memory and flashing exercises of the black period, she could make out bushy forms in the garden, saw that some were more compact than others, and as we were going down the walk, at the end of the second lesson, she recognized by their shape some hollyhocks she was passing. Those were the first objects she had been able to identify in all her years of blindness.

Following this great encouragement the next striking improvement was seen through the retinoscope. Day by day the veins of the optic nerve took on a healthier color, and in a short time there was a contraction of the pupil in noticeable accommodation to light. After nine lessons, the eye, which had first failed her and which had been least able to discern light, is beginning to show the same improvement as has gone on so gratifyingly in the other, and with this encouragement the patient and her family are enthusiastically looking forward to renewed sight for this sixty-three-year-old woman, who has been blind since her forties.

Very cordially yours,  
ELISABETH HANSEN.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

APRIL, 1927

### Demonstrate

#### 1. That palming improves the sight.

When both eyes are closed and covered with one or both hands in such a way as to exclude all light, one does not see red, blue, green or any other color. In short, when the palming is successful one does not see anything but black, and when the eyes are opened, the vision is always improved.

(Modern teachers say the colors will disappear as relaxation occurs. Don't concentrate on the colors.

Relaxation of mind, eyes, body is the goal when palming. Seeing black is not mandatory. Just relax and let the mind drift from one pleasant thought to another, remember, imagine a happy scene, objects in motion, action, color and clear like a movie in the mind.)

#### 2. That an imperfect memory prevents perfect palming and the vision is lowered.

Remember a letter "O" imperfectly, a letter "O" which has no white center and is covered by a gray cloud. It takes time; the effort is considerable and in spite of all that is done, the memory of the imperfect "O" is lost or forgotten for a time. The whole field is a shade of gray or of some other color, and when the hands are removed from the eyes, the vision is lowered.

#### 3. That when a perfect letter "O" is remembered, palming is practiced properly, continuously and easily and the sight is always benefited.

#### 4. That to fail to improve the sight by palming, or to palm imperfectly is difficult. To

fail, requires a stare or a strain and is not easy. When an effort is made, the eyes and mind are staring, straining, trying to see. When no effort is made, the palming becomes successful and the vision is benefited. Successful palming is not accomplished by doing things. Palming becomes successful by the things that are not done.

#### 5. That the longer you palm, the greater the benefit to your vision. Palm first for two minutes, then four minutes, six, etc., until you have palmed for fifteen. Notice the improvement gained in 15 minutes has been greater than that in four minutes.

Let the mind drift from one pleasant thought, image to another. Shift on objects in the imagination. Remember, imagine

Remember, imagine imperfect vision: The O unclear—Black print is a light black, grey and the white center and paper around the edge of the O a fuzzy grey blur. Strain and unclear vision occur.

Remember, imagine perfect, clear vision: letter O clear, black ink a dark black, white center and paper around the O a pure bright white. Relaxation and clear vision occur.

objects, scenery clear, in color, motion: bird flying, butterfly flying from flower to flower, tree branches, apple on a tree, see its details; antennas, colorful wings, legs... then it fly's through a field, lands on a high blade of grass, fly's off again to a distant tree, then back up close, then off again zig-zagging in the air, flying along the river..., imagine the wind blowing the trees, grass in a field, sun sparkling on the water. Hear the wind blow, feel the warmth of sun. Imagine walking into the scene, become part of it.

## Presbyopia: its Cause and Cure

By W. H. Bates, M.D.

Most people, when they reach the age of forty years or older, become unable to read or see things clearly at the near point, while their sight for distance is usually good. This is called presbyopia or middle-aged sight. It is sometimes, although infrequently, found in children.

Old Gentleman Cures Unclear Close Vision by Reading, Writing Fine Print

While it is sometimes very difficult to cure presbyopia, it is, fortunately, very easy to prevent it. Oliver Wendell Holmes told us how to do it in "The Autocrat of the Breakfast Table," and it is astonishing, not only, that no attention was paid to his advice, but that we should be warned against the very course which was found so beneficial in the case he records:

"There is now living in New York State," he says, "an old gentleman who, perceiving his sight to fail, immediately took to exercising it on the finest print, and in this way fairly bullied Nature out of her foolish habit of taking liberties at the age of forty-five or thereabouts. And now this old gentleman performs the most extraordinary feats with his pen, showing that his **eyes must be a pair of microscopes**. I should be afraid to say how much he writes on the compass of a half dime, whether the Psalms or the gospels, or the Psalms and the gospels, I won't be positive."

Presbyopia Cure

Persons, whose sight is beginning to fail at the near-point, or who are approaching the presbyopic age should imitate the example of this remarkable old gentleman. **Get a specimen of diamond type, and read it every day in an artificial light, (sunlight is best) bringing it closer and closer to the eye till it can be read at six inches or less. Or get a specimen of type reduced by photography until it is much smaller than diamond type, and do the same.** You will thus escape, not only the necessity of wearing glasses for reading and near work, but all of those eye troubles which now so often darken the later years of life.

Reading fine print prevents cataract and other eye problems. The smaller the print, the more vision improves.

Shifting point to point on tiny details of small objects; stone, jewelry... at close distances from the eyes also improves close vision. Practice relaxed, no effort, no force.

I remember an old darkey who said he was a **hundred and six years old, who was quite blind for distant objects, and was unable to read an ordinary newspaper at one foot or further.** With the aid of eye education, his vision for distance soon became normal, and his vision for near point also improved so that he could read diamond type at six inches without glasses.

The cause of presbyopia has been ascribed by most authorities to a hardening of the lens of the eye, so that the focus of the lens cannot be readily altered. This theory is incorrect. **When the lens has been removed for cataract or some other reason, most cases have become able, by education, to read fine print at six inches or less without glasses.**

Authorities on ophthalmology have always claimed that the focus of the eye was benefited by a change in the curvature of the lens. The evidence that the lens is not a factor in accommodation has only been recently proved. The eye changes its focus by a change in its length, brought about by the action of the muscles on the outside of the eyeball. In near-sightedness, the eyeball is squeezed by the external muscles and the optic axis is lengthened, i.e., the eyeball becomes elongated.

**The human eye acts in the same way as a photographic**

**camera acts.** If a picture is taken at the near point, the bellows of the camera is lengthened in order to focus the near object, while to focus objects at the distance the bellows of the camera is shortened. When the eye is at rest, it has the form of a perfect sphere. See more info on the lens, outer, inner eye muscles, accommodation in the July, 1926 'The Great Delusion' issue of Better Eyesight Magazine.

## Fundamental Facts

Memory and Imagination

In studying the cause of presbyopia it is well to remember or to demonstrate some fundamental facts. In the first place, the printed page has more white exposed than it has black. One can look at the white spaces between the lines and hold the book very close to the eyes four or five inches or more without any discomfort, but if one looks at a letter or part of a letter and tries to keep his mind fixed on that one part continuously, sooner or later the eyes become tired, the mind wanders, and the vision becomes imperfect. Looking at the white spaces and imagining them to be perfectly white, is a rest and can be accomplished more readily than improving the black letters by an effort.

Shift when looking at the spaces and when looking at the letters.

When the white center of a letter "O" is seen gray, blurred and indistinct, one is seeing something that is not there. In other words, imperfect sight is never seen; it is only imagined. With perfect sight one may see the white center of the letter much whiter than it really is, or whiter than the rest of the card. By covering over the black part of the letter "O" with a screen and exposing only a part of the white center, one can demonstrate that the whiteness in the center of a letter "O" when seen perfectly, is not really seen, but imagined. Imagination of perfect sight is easier than imagination of imperfect sight. When one remembers a letter "O" perfectly, it is accomplished without effort, and it may be remembered more or less continuously, but if a letter "O" is imagined imperfectly

Shift on the letter O and remember, imagine, see it clear with the eyes open, then in the imagination with eyes closed, then with the eyes open again. See it dark black, clear with a bright, pure white center.

without a white center, blurred, or cloudy, it prevents the letter from being seen, remembered or imagined clearly as an "O." To improve the memory or the imagination of an imperfect "O" requires time, a second or longer. To make an attempt to remember an imperfect "O" continuously is difficult, requires much trouble, causes pain in the eyes and head, and discomfort of various kinds in all the nerves of the body. The memory of imperfect sight is difficult, because it requires so much effort to maintain it. In spite of all the efforts that are made to remember imperfect sight, one soon demonstrates that the imperfect letter "O" will not be remembered continuously. It is the things that we stop doing that promote the memory of perfect sight. We do not need to practice something new nor learn by mental training how to do something that we have never done before. When a patient is convinced of these facts it is difficult to realize why he keeps on doing wrong, when using his eyes correctly is so much easier and brings renewed vision.

### Fine Print

When people are able to read fine print with perfect sight at six inches or further, the white spaces between the lines are seen or imagined whiter than the rest of the card. The ability to imagine the white spaces between the lines to be very white is accomplished by the memory of white snow, white starch or anything perfectly white, with the eyes closed for part of a minute. Some patients count thirty while remembering some white object or scene with the eyes closed. Then, when the eyes are opened for a second, the white spaces between the lines of black letters are imagined or seen much whiter than before. By alternately remembering something perfectly white with the eyes closed and opening them for a few seconds and flashing the spaces, the vision or the imagination of the white spaces improves. One needs to be careful not to make an effort or to regard the black letters. When the white spaces between the lines are imagined sufficiently white, or as white as they can be remembered with the eyes closed and with the eyes open; then, look at the black letters, see them clear, the black letters are read without effort or strain, or without the consciousness of regarding the black letters.

#### The Thin White Line

Many people discover that they can imagine a thin white line where the bottom of the letters comes in contact with the white spaces. **This thin line is very white, and the thinner it is imagined to be, the whiter it becomes.** When it is imagined perfectly, the letters are read without the consciousness of looking at them and the vision or imagination of the white is very much improved. This thin white line can be imagined much whiter than any other part of the page, and is more easily imagined or seen than any other part. **Of course, the eyes have to shift from the thin, white line to the letters in order to see them, but the shifting is done so readily, so continuously, so perfectly that the reader does not notice that he is constantly shifting.** When the vision of the thin, white line is imperfect, the shifting is slow and imperfect and the vision for the letters is impaired. The memory or the imagination of the thin, white line is usually so easy, so perfect and so continuous that everything regarded is seen with maximum vision. Patients with **cataract** who become able to imagine this thin, white line perfectly, very soon become able to read the finest print without effort or strain, and the **cataract always improves, or becomes less.** Patients with **hypermetropia, astigmatism, squint, diseases of the retina and optic nerve are benefited in every way by the memory or the imagination of the thin, white line. Reading fine print with perfect sight benefits or improves all organic diseases of the eye.**

Another reason Dr. Bates has the person remember, imagine and look at the white spaces, white line is that: white functions as with 'light', and activates the eyes retina. For this reason there are eyecharts with white letters printed on a black, blue... background. They are easier to see and relaxing especially for patients with low vision.

#### Fine Print

Read fine print for clear close vision.  
See the 'Swing':  
Place the fine print 8 in. from the eyes and the thumb 5 in. from the eyes in front of the fine print and 1/4 in. to the left of a letter. Move the head and eyes side to side and see the thumb move opposite the movement of the head/eyes and the fine print move in the same direction with the head/eyes. This prevents staring, keeps the eyes moving, relaxed and vision clear. See the thin white line.

### The Universal Swing

There are a number of varieties of the **optical swing** which prevent, improve or cure presbyopia. Of these, perhaps the best one of all is called the **universal swing**. When one can practice the universal swing, and at the same time test the imagination of the thin, white line or the white spaces between the lines, the presbyopia is usually very much benefited. The universal swing differs from all other swings in that the eyes, as well as the body, are all moving in the same direction as other objects seen or imagined.

If you hold your finger about six inches from your eyes, by moving your head from side to side it is possible to imagine the finger to be moving in the opposite direction. This is the **variable swing**. While the eyes are moving in the opposite direction to the movement of the finger, all other objects can be imagined in the same way. (to be moving opposite the movement of the finger. Also, close objects will show most appearance of moving opposite to the movement of the eyes, head). Usually distant objects do not swing as much as the finger and may appear to be almost stationary (or appear to move in the same direction the eyes/head move to and also appearing to move opposite the movement of the finger.)

With the **eyes closed**, one can remember the finger moving from side to side and imagine that all objects to which the finger is connected, directly or indirectly, appear to move in the same direction, and the same distance as the finger moves, the only difference being that the eyes move with the finger and with everything else, while with the eyes open in the variable swing, the eyes (and head) always move in the opposite direction to the movement of the finger. One can improve the universal swing by remembering the movement of the finger with the eyes closed. This swing can be demonstrated more readily with the eyes closed than with the eyes open.

This paragraph does not state whether the eyes/head are physically moved side to side when the eyes are closed.

There are different impressions seen by the minds eyes when the eyes/head are not moved and when they are moved:

+I notice that when I do not move the eyes/head side to side, left and right when the eyes are closed, while imagining seeing the finger move opposite, right and left, the closed eyes will follow the movement of the imaginary finger.

+If the eyes/head are moved left and right when the eyes are closed and imagining the finger moving opposite, the closed eyes will move opposite the imaginary moving finger the same as when the eyes are open.

It is relaxing to move the eyes/head side to side when imagining the finger moving opposite with eyes open and closed.

## Oppositional Movement with Finger and Thumb

By holding the diamond type about six inches from your eyes and holding the thumb about an inch nearer the eyes, and about one-quarter of an inch to the left of one letter of the diamond type, one can demonstrate that when the head and eyes move from side to side, the thumb appears to move opposite, while the fine print appears to move with the movement of the head and eyes. At once, the fine print improves sufficiently to be read and the thin white line also becomes more perfectly seen or imagined.

Some patients are able to move the thumbnail more or less rapidly close to the bottom of the letters and read the fine print, perfectly continuously and rapidly. The thumbnail moving from side to side improves the imagination of the thin, white line, and when the thin, white line is imagined sufficiently white the letters are flashed sufficiently black to be distinguished.

Moving the head from side to side prevents the stare and in this way the vision is improved, but when the eyes and head move in a horizontal direction to the right, the movement stops before the head and eyes can move to the left. When the movement stops, time is given for the stare, or an effort to be made and the vision is lowered. When the head and eyes move in a circular direction, the movement becomes continuous and the vision is also more continuous. The **circular swing** may be practiced with the head and eyes moving in the orbit of a large circle. When the movement of the head and eyes in a circular direction is shortened, the vision is further improved. However, one has to realize that in a short, circular swing, the movement stops readily, thereby lowering the vision. Patients should demonstrate that a short, circular swing, while being a greater benefit, may be unconsciously stopped, while the large circular swing is more apt to be continuous. When the vision becomes lowered, while reading with the help of the circular swing, it is evidence that the circular swing has been unconsciously stopped.

Practice drawing large, medium, small Circular, Elliptical and Figure Eight Swings in the sunlight. Draw counter-clockwise, clockwise, counter-clockwise... Draw in the air with the eyes, hands and nosefeather, draw on paper.

Draw the Figure Eight, Infinity Swing – See chapter 16 in the book: Do It Yourself – Natural Eyesight Improvement.

Another cure of presbyopia is accomplished with the aid of the memory. When one can remember a color, letter or an object perfectly, presbyopia disappears and the vision becomes normal. Perfect memory is always accompanied by perfect relaxation with perfect sight.

## Stories From The Clinic Presbyopia

By Emily C. Lierman

I have recently had a few cases of presbyopia which were cured in a short time. One was a woman sixty-three years of age who did fine sewing for her livelihood. She had worn glasses for more than thirty years and during the past two years her eye specialist found it difficult to fit her with glasses correctly. She had purchased her last pair the day before she came to me, and told me they made her so nervous and irritable that she could not possibly wear them more than half a day.

Her vision for the distance was normal, 15/15 with each eye separately. I gave her a small test card to hold, which has the Fundamentals by Dr. W. H. Bates on the opposite side and asked her to read what she could on it. She held it at arm's length and said that she knew there was some kind of print on the card but could not tell what it was. In despair she looked at me and said, "I fear you will have a hard time getting me to read this." I gave her the small booklet containing the **microscopic type** and also a small card with diamond type. I placed the booklet at the lower part of the Fundamentals card and the diamond type card in the center. She was told to hold these about twelve inches from her eyes and not to worry about reading the print. The patient looked at me in a blank sort of way wondering how it was possible to cure presbyopia in this manner. As she was optimistic, it was easy for me to treat her. She was willing to believe that I could do for her what had been done for others whom she knew had been cured by Dr. Bates. I told her to look at the small white spaces between the lines of print in the booklet, close both eyes and remember the white spaces. She could remember them white with her eyes closed. I told her to open her eyes and again look at the white spaces. She said they appeared whiter than they had the first time. Again I told her to close her eyes and remember the white spaces and to open them in less than a second, look at the white spaces of the diamond type card, close her eyes and remember the white spaces; then for just a second to open her eyes and look at the white spaces of the Fundamentals card. I told her to keep this up while I was out of the room and left her to herself for almost a half hour. Before leaving I warned her about trying to read the print, telling her that she was to flash only the white spaces. When I returned she looked at me very much frightened and said "What am I to do, I cannot help but tell you the truth, I can read this Fundamentals' card." I noticed that she held the Fundamental card eight inches from her eyes instead of twelve. She read one sentence after another for me.

I told her to be careful about staring at the type, and be sure to look at the white spaces directly below the sentence she was reading instead of at the letters. (Modern teachers state to look at the white spaces, remember/imagine the white spaces clear, pure, bright glowing white, then, when the eyes are relaxed; look directly at the black letters and read the words. Trying to read by looking at the white spaces while seeing the words in the peripheral field is diffusion, the opposite of central fixation and causes strain and unclear vision. Always look directly at the object you want to see clear and shift, move the eyes upon it. After reading a sentence of the Fundamentals card she would shift to the white spaces of the blue booklet and then to the spaces of the small card and back again to the Fundamentals card. The treatment lasted about one hour. I told her to telephone me the next day and let me know if she had forgotten what I had directed her to do. She called, and said that she was able to read some of the Bible type as well as all of the print on the Fundamentals card. Having read my book before she came for treatment, she knew that staring produced much

discomfort and realized that she should blink frequently. Her knowledge of the benefits of blinking helped her to be cured more quickly than the usual case of this kind. The last time that she telephoned she reported that her sewing was much easier to do. She has entirely discarded her glasses and promises never to wear them again.

The second patient was a man fifty-eight years of age, a bank teller. He had heard of a bank president who had been cured by Dr. Bates. Then he obtained my book and Dr. Bates' book, "Perfect Sight Without Glasses," from the public library. He understood the directions described in each book, but there were times when he was unsuccessful in getting good results, so he came to me for help.

His sight was tested for the distance and he read 15/30 with each eye separately, although he saw some of the letters double. He complained of headache and pain in the back of his eyes, especially while working. He was then directed to **palm** and to imagine that he was adding accounts. He said it caused more strain and discomfort in his head and eyes. He said that it would be impossible to palm during business hours. I told him that it would not be necessary, that there were other things that he could do to prevent his headaches and eyestrain. I taught him to **blink and shift all day long like the normal eye does in order to keep the eyes relaxed and in good condition**. He was told to **remember something perfectly, easily and without effort**. He said he could remember the ocean with the tide coming in and that every seventh wave was the largest. Knowing the game of football helped him to imagine the size, color and shape of the ball. All these little details which **improved his memory** helped to **relax his mind** while his eyes were closed.

After ten minutes, he was instructed to stand with his feet about one foot apart and **sway his body to the right and then to the left**. As the window was close by, I directed him to look off in the distance and notice objects moving with his body, eyes and head, while things up close seemed to move opposite. He said he was hoping I would let him do that for quite a while because the bad headache he had just before coming to me, was disappearing.

Then I told him to keep up the sway, looking out of the window and then toward the test card. As soon as he saw a letter I told him to look away, keeping up the sway all the while. This time he read 15/10 with each eye separately. When I gave him the Fundamental card to read, he could see only sentence No. 2. All the rest of the card was very much blurred to him. Again I directed him to stand and sway and notice distant objects moving with his eyes and body, while things close appeared to move opposite.

I then had him sit in a chair with his back to the sun and told him to remember the sway of the body with his eyes closed. In a short time he began to practice again with the Fundamental card, and this time he read up to No. 8 by imagining the white spaces whiter than they really were. I watched him as he tried to read further and when he began to read the small type, he stopped the blinking unconsciously and stared at the print. I noticed that his forehead became wrinkled and that he squeezed his eyes almost shut to read. (Squinting) I stopped this and asked him to close his eyes quickly and tell me how he felt. He had produced a strain that caused his head and eyes to ache. I reminded him that by squeezing his eyes and staring and making an effort, a strain had been produced. While his eyes were covered with the palm of one hand, he remarked, "Now I realize what I must do all day long to see without straining." I told him that when patients found out for themselves that staring brings on tension and pain, they are cured much more quickly than others who do not realize this fact. He was cured in three visits.

Sway the body left and right in front of a window. See distant objects move with the body, eyes in the same direction and close objects move in the opposite direction. Sway and alternate looking out the window at distant objects, then at a dose eyechart, shifting quickly for a 'fraction of second' on a letter, then back to objects outside the window.

My third case of presbyopia, which took the longest time to cure, was a music teacher forty-nine years of age. It was very hard to convince her that I could benefit her.

Her vision for the test card with each eye was normal, 15/15. When I gave her the Fundamental card to read, she was quite positive that she would never read any of it without her glasses. I gave her a "Better Eyesight" Magazine and told her to look at the title. She said that she could see it, but that the type was blurred as she held it at arm's length from her eyes.

She was told to close her eyes and palm with one hand and remember one of the letters of the test card that she had read at fifteen feet. Then, in less than a moment's time, I told her to remove her hand from her eyes and look at the white spaces of the Fundamental card. She did this a few times and then began to smile. She said the print was beginning to clear up, but that it soon faded away and she became unable to read it again. When I told her to avoid looking at the type, she laughed. Immediately I became convinced that this was the way she read her sheet music. She looked directly at the notes and lowered her vision by staring. By closing her eyes and remembering white spaces, then opening them and looking at the white spaces, words began to clear up and she became a very different person. When she was successful in doing as I directed, she read up to No. 3 of the Fundamental card. I saw her once a week for more than a month before she was able to read the entire Fundamental card, eight inches from her eyes. She was told to place the small black test card on the piano near the sheet music and to frequently flash a letter of the card; then read her music. In this way she was cured. All patients cannot be treated in the same way, no matter what trouble they may have with their eyes. Eyestrain has a great deal to do with the mind and the Bates Method has surely proved it. It is ok to look directly at the print as long as the eyes shift on it. Shifting, central fixation, blink. Avoid staring, squinting, effort to see clear.

Flash - two meanings:

1 = To look at, shift on a object quickly for a 'fraction of a second' and then close the eyes to avoid giving the eyes, mind a chance to use strain, effort to see. For that fraction of a second the letter is often clear and with practice the letter remains clear longer.

2 = A flash of clear vision lasting a fraction of a second or longer to minutes, hours, weeks, permanent.)

## Case History

January 14, 1927

Mr. Robert C. Fager,  
38 South 17<sup>th</sup> St.  
Harrisburg, Pa.

Dear Sir:

In reply to your letter of the 11<sup>th</sup> concerning Dr. Bates' book "Perfect Sight Without Glasses," I would like to say that after reading this book about five years ago and practicing the methods outlined in the book, I was able to lay aside my glasses which I had been wearing more or less for twenty-one years. I have not used my glasses since that time and have noted no bad effects, in fact, I have continued to feel better and gain in weight until I am now, at forty-two years of age, better than I ever was.

I still have some slight astigmatism in my right eye, but feel that if I would really take the time and trouble to practice Dr. Bates' methods more thoroughly, I would easily overcome this difficulty.

When I used to wear glasses, I would get headaches in a few minutes time if I tried to read without them. Since learning Dr. Bates' eye exercises, I have had no trouble reading as long as I wanted to without any headaches.

If you have had no operation on your eyes, I feel sure that you can obtain normal vision if you will conscientiously practice the methods described in Dr. Bates' book.

Sincerely yours,  
W. J. DANA,  
Professor of Experimental Engineering,  
North Carolina State College of  
Agriculture and Engineering.

## Questions and Answers

Q - In case of illness where one is unable to practice with the Snellen test card or stand up, what method is used?

A - Blink frequently and shift your eyes constantly from one point to another. Turn your head slightly from side to side on the pillow or close your eyes and think of something pleasant, something that you can remember perfectly and let your mind drift from one pleasant thought to another.

Q -The sun shining on the snow darkens and almost blinds my vision. What is this caused by, and how can I obtain relief?

A -This is caused by a strain and can be relieved by practicing blinking, shifting and central fixation all day long. Notice that stationary objects appear to move in the direction opposite to the movement of your head and eyes. Notice that the trees or other near objects move opposite while the horizon or distant objects move with you.

Poor nutrition, drugs, some herbs, can impair the eyes adjustment from light to dark, dark to light.

Q - Does wearing rubbers for any length of time hurt the eyes?

A - Yes, it does not give the blood an opportunity to circulate properly.

Q - It is very hard for me to think in terms of black and white. Is there some other method which is just as beneficial?

A - Yes, letting your mind drift from one pleasant memory to another will accomplish the same results.

Q - Is it necessary to practice with the Snellen test card if you follow the method otherwise?

A - Yes, it is advisable to keep up your daily practice with the test card for at least a few moments. This will improve your memory and the memory must be improved in order to have the vision improve.

## Perfect Sight Without Glasses

By W. H. Bates, M.D.

Increased demand has enabled us to reduce the price from \$5.00 to \$3.00 per copy.

The book contains:

The principles and methods fundamental in the cure of imperfect sight by treatment without glasses.

### METHODS OF TREATMENT described in

### Stories from the Clinic

By EMILY C. LIERMAN

This valuable book fully explains:

The author's application of Dr. Bates' method of treatment to each individual clinic case.

The symptoms and cure of imperfect sight by treatment without glasses, and how readers can benefit themselves.

"Stories from the Clinic" is a contribution to the practice of Ophthalmology.  
Reduced Price, \$2.00

Both Books Now \$5.00

Books of 15 reprints from Medical Journals by W. H. Bates, M. D., reduced from \$1.50 to \$1.00 or sold separately at 10c each.

List of reprints sent on request.

Large Snellen "C" cards reduced from 96c to 50c each. All others reduced from 75c to 50c. Fundamental cards, including Small "C," Fundamental, Black "E," Inverted "E" and Numerical Cards are available now. This is a handy pocket or vest size and no one should be without one. 10c each.

Central Fixation Publishing Company  
383 Madison Avenue, New York City

## "LERNT WIEDER SEHEN"

By Elisabeth Friedrichs

This book was written (in German) for the purpose of introducing Dr. Bates' Method to German-speaking people. Those who wish to learn more about the method of curing imperfect sight by treatment without glasses, will be interested to know that this book "Lernt Wieder Sehen" will be followed shortly by the publication of the German translation of "Perfect Sight Without Glasses," by W. H. Bates, M.D.

"Lernt Wieder Sehen" is bound in cloth or paper. A small fundamental test card is included with the book.

Sold by the Central Fixation Publishing Co., 383 Madison Ave., New York, N. Y. Price (cloth) \$1.50, (paper) \$1.00.

## "LERNT SEHEN" (LEARN TO SEE)

A monthly magazine for improving the vision by treatment without glasses.

3.50 marks per year. Quarterly, 1 mark. Single copies, 40 Bfg.

Published and obtained from Paul Schreyer, Grimma, Saxony, Germany.

"Lernt Wieder Sehen" may also be obtained directly from the same address.

Review from German Newspaper, Die Leubniskunst, Leipzig.

"This work which has just appeared, is a contribution in the field of treatment of the eye and has even now found recognition far and wide. We point to an article in this number of the issue, by Mrs. Friedrichs, and express the wish that through her, all those who have had imperfect vision may be given the power to see again or will be able to discard their glasses."

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MAY, 1927

### Demonstrate

1 - That a short, swaying movement improves the vision more than a long sway. Place the test card at a distance where only the large letter at the top of the card can be distinguished. This may be ten feet, further or nearer. Stand with the feet about one foot apart and sway the body from side to side. When the body sways to the right, look to the right of the card. When the body sways to the left, look to the left of the card. Do not look at the Snellen test card. Sway the body from side to side and look to the right of the Snellen test card, and alternately to the left of it. Note that the test card appears to be moving. Increase the length of the sway and notice that the test card seems to move a longer distance from side to side. Observe the whiteness of the card and the blackness of the letters. Now shorten the sway, which, of course, shortens the movement of the card. The card appears whiter and the letters blacker when the movement of the card is short, than when the movement of the card is long.

2 - Demonstrate that when the eyes are stationary, they are under a tremendous strain. Stand before the Snellen test card at a distance of fifteen or twenty feet. Look directly at one small area of a large letter, which can be seen clearly. Stare at that part of the letter without closing the eyes and without shifting the eyes to some other point. The vision soon becomes worse and the letter blurs. Stare continuously, and note that the longer you stare, the more difficult it is to keep the eyes focused on that one point or part of the letter. Not only does the stare become more difficult, but the eyes become tired; and by making a greater effort, the eyes pain, or a headache is produced. The stare can cause fatigue of the whole body when the effort is sufficiently strong and prolonged.

Stand, face the eyechart, sway side to side. Sway right and look away to the right of the card. Sway left and look to the left of the card. Sway and look right, left, right, left... See the card appear to move in the opposite direction the eyes, body move, look to. Sway, move the body, eyes longer left and right and see a longer movement of the card. Sway shorter (6 in. or 1-3 in.) side to side and see the card move shorter and the vision become clearer. Small shifts, movements of the eyes (saccadic) and perfect central fixation on objects=clear vision.

Stare at one part of the E (dot). Eyes immobile, not shifting-experience strain and blur. Shift part to part on the E and experience relaxation and clear vision. Avoid staring. Let the eyes move.

## Myopia or Near-Sightedness

By W. H. Bates, M.D.

Myopia, or nearsightedness as it is commonly called, is caused by a strain to see at the distance.

In myopia, the eyes are habitually focused for a point about twelve inches or less. In high degrees of myopia, the eyes may be focused at less than twelve inches, ten inches, six inches, three inches or nearer to the eyes. Some patients can read the test card perfectly when they regard it close enough to the eyes. They may be able to read the diamond type when held two to three inches from the eyes. In low degrees of myopia, the vision may be almost as good as in the normal eye.

When the normal eye is at rest, there is no myopia. When the normal eye reads at twelve inches, with an effort or a strain, it becomes temporarily myopic. In order to produce myopia in the normal eye, it is necessary to strain or make an effort to see. In all cases, myopia is caused or is accompanied by an effort or a strain to see at the distance.

Many children, at ten years of age, may have normal eyes, which remain normal until they begin to strain and make an effort to see at the distance. Such patients are cured of their myopia when they can regard the Snellen test card or other objects without any effort or strain.

It can be demonstrated, with the aid of the retinoscope, that myopic patients do not have myopia all the time. When regarding a blank surface, where there is nothing to be seen, or when the patient makes no effort to see, the retinoscope always demonstrates the absence of myopia. When, by treatment the myopic eye does not strain nor make an effort to see at the distance, the myopia becomes less or may disappear altogether.

**The quickest cures of myopia are accomplished with the help of the memory, the imagination and central fixation.**

### Memory and Imagination

A perfect memory and perfect imagination cures myopia under favorable conditions. Patients who have a good memory of mental pictures have no myopia when the mental pictures are remembered or imagined perfectly. There are near-sighted people who, after a course of eye education, can look at a Snellen test card at ten feet or further and remember or imagine the white part of the card perfectly white and the black letters perfectly black. When this is accomplished, the myopia improves.

When school children regard the blackboard, they often half-close their eyelids, or stare and strain to see and thus produce myopia. When they can remember a mental picture of some small letter, and remember it as well with the eyes open as with the eyes closed, normal vision and a temporary cure of their myopia is obtained.

In myopia and other phases of imperfect sight, the white centers of all letters are imagined less white than the rest of the card. When the patient becomes able to imagine the white centers with a white background to be whiter than the rest of the card, the vision is improved and there is no myopia.

### Central Fixation

When the vision of myopic patients is imperfect, it can always be demonstrated that the point regarded is not seen best, and other parts of a letter may be seen equally well or better. When the patient becomes able to remember or imagine one part of a letter or an object best, the myopia is lessened and the vision improves. When the strain is prevented, by shifting from one side of the letter to another, the letter appears to move from side to side. The vision may then become normal and the myopia disappears.

### Universal Swing

The universal swing is of great value in the treatment of myopia and may be practiced as follows: Regard the Snellen test card at ten feet. Hold the forefinger of one hand about six inches to the front and to the side of one eye. The finger may be held at a nearer distance and good results obtained. Then move the head a short distance from side to side, without looking at the finger, and without trying to read the letters on the distant Snellen test card. Do not look directly at the finger, or the apparent movement becomes modified or stops. Now close the eyes and remember the finger as moving from side to side. If the hand and finger are placed in the lap, one may still be able to remember the moving finger. With the help of the imagination, one may realize that when the finger moves, the hand which is fastened to the finger also moves at the same speed and to the same extent. The same is true of the arm, the elbow, the shoulder, all moving with the finger.

The universal swing is characterized by the fact that one becomes able to imagine the eyes are moving with the finger when the eyes are closed, but when the eyes are opened, they usually move opposite to the movement of the finger.

The above sentence can be interpreted a couple ways:

+If the head is moved left and right when the eyes are closed, the minds eyes can imagine seeing the finger move opposite-the imaginary finger will move opposite the movement of the head/closed eyes.  
+If the head is not moved side to side but the finger is imagined to move left and right, the minds eyes (and physical closed eyes) will move with, in the same direction as the imagined moving finger.

When the eyes are open, one can note that by moving the head from side to side, near objects move opposite to the direction of the head and eyes, while distant objects may appear to move in the same direction as the head and eyes.

When one is regarding the Snellen test card, the letters of the card move with the head and eyes, and when the letters move, one can, of course, imagine the whole card to be moving with the head and eyes. Under these conditions, the eyes become more thoroughly relaxed with a consequent improvement in the vision and lessening of the myopia. When the universal swing is practiced

Finger placed 6 inches or less in front of and to the side of one eye.  
Eyechart 10 feet away.  
Move the head side to side without looking at the finger and without trying to read the eyechart. The finger appears to move in the opposite direction the head, eyes move to.  
The distant eyechart appears to move in the same direction the head, eyes move to.  
Close the eyes and imagine the finger moving and notice the hand, arm... all objects connected to the finger move with it. See the distant chart move opposite in the imagination.

correctly, the movement of the letters and the card is slow, short (about one-quarter of an inch), and easy.

One should practice the universal swing for a sufficient length of time to become able to imagine the letters of the Snellen test card moving in the same direction as do the head and eyes. **It is impossible to imagine the Snellen test card moving with the head and eyes unless some nearer object moves opposite to the movement of the head and eyes.**

Oppositional movement. Close objects appear to move opposite the direction the eyes, head, body move. Distant objects appear to move in the same direction.

### A Test of the Imagination (with Oppositional Movement)

There are a number of phenomena which always occur when the universal swing is practiced. With the back of one Snellen test card toward the patient and placed ten feet away from him, and with the face of the second towards him and placed at twelve feet, both cards can be so arranged that the patient can observe an open space between the two of about four or five inches in width.

+When the patient moves the head and eyes to the left, the space between the two cards becomes less and one can imagine the near card moving to the right, while the more distant card with its letters appears to move to the left.

+When the head and eyes move to the right, the near card appears to move to the left, the space becomes larger between the two cards, and the patient can imagine the face of the more distant card moving to the right.

+When the vision is normal and the head and eyes move from side to side, the near card moves opposite, while the more distant card moves in the same direction as the head and eyes.

When the vision is imperfect and the head and eyes are moved from side to side, the near card moves opposite, while the more distant card may also move opposite to the movement of the head and eyes, or it may stop or move in an irregular, jerky manner. When one letter of the distant card is seen imperfectly or when one side or part of a letter is imagined imperfectly, consciously or unconsciously, the movement of the more distant card is modified and very irregular.

When the imagination of a small part of an unknown letter is correct, the swing of the more distant card becomes normal, the card moves from side to side in the same direction as the head and eyes and moves slowly, easily, and continuously. By repetition, one may become able to imagine a part of an unknown letter with the eyes open nearly as well as with the eyes closed, and the imagination of an unknown letter may improve until the imagination becomes as good or better than the sight. The distant card always moves in the same direction as the movement of the head and eyes, when a part of an unknown letter is imagined perfectly. The reverse is also true, that when the distant card does not move with the head and eyes, the imagination of an unknown letter is imperfect.

The patient should learn to practice the universal swing not only indoors, with the help of the Snellen test card, but it should also be practiced while walking or driving. Some people can demonstrate that all objects become clearer or more distinct by imagining them to move with the head and eyes. This result, however, cannot be obtained unless nearer objects appear to move opposite to the movement of the head and eyes.

When the universal swing is practiced, it is possible for patients with myopia to improve the vision to normal, and the myopia is no longer apparent. Many patients with myopia complain that the benefit obtained from palming, swinging, central fixation and other methods is only temporary. If by continued practice of these methods, however, the flashes of improved vision do not become more frequent and last longer, the universal swing is usually beneficial.

Some patients have difficulty in practicing the universal swing successfully. They are benefited in many cases by imagining the universal swing with the eyes closed for a longer time than with them open.

Sway left and right. The close chart moves in the opposite direction the head, eyes move to. The distant chart moves in the same direction. The two charts are placed apart so a space of about 4-5 in. width is seen between them. This helps the eyes see the appearance of oppositional movement.

### A Familiar Card (Memory and Imagination)

When patients practice reading a familiar test card a number of times daily, it is not very long before the letters become memorized. The criticism is made that patients do not see the letters, they only remember or imagine them. It is true that when the sight is perfect, the imagination as well as the memory is perfect. Practicing with the Snellen test card with the help of the memory and the imagination is a benefit. Myopia is always relieved or corrected with the aid of a perfect memory or a perfect imagination. Practicing with a familiar card is one of the quickest methods of curing myopia temporarily or permanently. The more perfectly the letters of the Snellen test card are remembered or imagined, the more completely is the myopia relieved.

## Case History

A boy, eight years old, practiced with a familiar Snellen test card twice daily for six months. His mother was discouraged because she said that her son had learned the letters by heart and one could not tell whether he saw the letters correctly or just imagined them. A number of Snellen test cards which the boy had never seen before were used in testing his sight. Much to the surprise of his mother, he read the strange cards just as readily, if not more readily than he did the familiar card. This, of course, convinced his mother that his vision was normal for the strange test cards. She was very curious to know why.

With the aid of the retinoscope, she was able to see the red reflex in the pupil and to imagine a cloud moving from side to side in the same direction as the retinoscope was moved. This always occurred when the patient had normal vision with the familiar or unfamiliar card. When he imagined the letters imperfectly, his mother demonstrated that the shadow moved in the opposite direction to the movement of the retinoscope. It was not difficult to convince her then that, when his vision for the familiar card was perfect, he had no myopia.

Many patients with myopia have been tested and in all cases **when the memory was perfect, the sight was perfect.** As a rule, school children who had good memories were more readily cured than other children. In most schools young children under twelve years of age, who had myopia, were temporarily or permanently cured by the use of the familiar Snellen test card.

## The Snellen Test Card

The Snellen test card, while it is of value as a test for the ability of the children to see, is of far greater usefulness as a means for improving the sight.

Acute myopia is usually cured by very simple treatment. Children under twelve years of age who have never worn glasses are usually temporarily cured by alternately reading the Snellen Test Card and resting their eyes by palming.

I have found that in schools where the Snellen Test Card is visible continuously, the vision of the pupils is always improved and that the children in the higher grades acquire more perfect sight than they had when they first entered school. Most children demonstrate that while the Snellen test card improves the vision that it is also a benefit to the nervous system. It prevents and cures headaches, lessens fatigue, encourages the children to study, and increases the mental efficiency.

## STORIES FROM THE CLINIC

### Cases of Myopia

By Emily C. Lierman

A woman, forty-six years of age, who has had myopia as long as she can remember, placed herself under my care, but doubted that I could give her a permanent cure for near-sightedness.

About forty years ago, noticing that she stumbled over objects which were easily seen by others with good vision, her parents had her fitted with glasses. After having had her glasses changed about five times, she came to me for help. At the oculist's advice, she tried faithfully to wear the last pair of glasses continuously, for at least a week, and then returned to him. The glasses were much stronger than those she had previously worn and magnified everything to such an extent that it was impossible to go without them. (or impossible to wear them). Although the patient was skeptical about the Bates Method, she was desperate and willing to believe anything in order that she might be able to do without glasses. I feared that with that attitude she would not continue with the treatment, but I found that I was mistaken. She was very faithful in practicing what I directed her to do.

Now, after four months of treatment and advice, which was carried out religiously by the patient, she drives her car and reads signs, sometimes half a city block away, without glasses. This patient is not entirely cured, although for days at a time she reads 10/10 with the test card and holds her book for reading at normal distance.

In the beginning, it was hard to convince her that it was strain which produced her myopic condition. In treating myopic cases, Dr. Bates and I have proved that all cases of myopia cannot be treated in the same way. This patient's vision with the test card in December, 1926, was the same in both eyes; namely, 10/70. The 70-line letters, however, were very much blurred. Palming helped temporarily, and her vision improved to 10/40 with the aid of **blinking, swinging the body a short distance from left to right and flashing one letter of the test card with each sway of the body.** I realized that this was not helping her enough and that she should progress more rapidly, so I experimented with other methods of treatment.

One day she came to me and told me that I was improving her mental condition.

Distant Flag

Window at close distance

Swing right>  
The flag moves right and the window moves left<.

5 Ft. C

+Two small identical eyecharts. Place one chart at 5 ft. and the other chart closer to the eyes.

+Look at the distant chart. Look at the white opening at the right of the C and the white center. Imagine it pure, bright, clear white, whiter than areas of the paper away from the C.

+Do this with the eyes open, then in the imagination with the eyes closed.

+Eyes open: Look at the C on the close chart, then distant, then close. Repeat imagining the white area pure, clear white with the eyes open, closed, open when looking at the close and distant charts.

+Then; Look at and shift part to part directly on the C and remember, imagine it dark black and clear white with eyes open, closed, open on the distant and close charts.

+Then; practice on smaller letters at different distances.

Swing left and right in front of the window and see distant objects (mountain, flag) move in the same direction with the body, head, eyes while close objects (window) appear to move opposite the body, head, eyes. Blink.

Next: Stop swinging. Sway a short distance 1-4 inches... Place a curtain cord in the center of the window. Practice shifting on the close cord and the distant flag.

Shift on the cord. Switch to the flag and shift on it. Switch back to the cord and shift on it, then the flag, cord, flag... Practice with both eyes together and one eye at a time.

## Swinging and Oppositional Movement

Knowing what good results Dr. Bates had had with the **universal swing**, I used that with my patient. I had her stand before a window and told her to swing from left to right, as I was doing. A decided swing of the body from left to right made distant buildings, flag-staffs and other distant objects appear to move with her body, head and eyes. I encouraged her to keep looking off at the distance while she explained to me how the things at the near point appeared to move. With great surprise in her voice she said: "The window, curtains, shade cord, and other things nearby appear to move in the opposite direction." (Oppositional Movement) I continued swinging with the patient, encouraging her to keep it up for five or ten minutes. I watched her eyes closely to be sure that she was blinking. She noticed that I was watching her and made an unusual remark, which I did not expect from her, because myopic patients usually stare without knowing it. She turned to me and said. "You are watching to see whether I blink or not. Don't worry about that, it feels more comfortable to blink while I am swinging." She also said that she noticed that her eyes felt less heavy while she kept up the swing and that the sun seemed to shine brighter than she had ordinarily noticed it at any time. All the while she was talking she kept up the swing.

When I made a test of her vision again before her first treatment was over her vision improved to 15/15. The patient was much excited and asked if this improved condition of her eyes would continue. I answered, "Yes, if you will remember every day to practice the universal swing frequently."

To vary the treatment for home practice, I gave her two small Fundamental cards with the test letters on the opposite side. She was directed to place one card on her desk as she sat or stood about five feet from the card. The same kind of a card with the same letters was to be held in her hand. She was to begin with the largest letter, which is seen by the normal eye at fifty feet. Looking at the "C" to the right of it where the small opening is, closing her eyes and remembering the small opening and imagining the opening and center of the "C" whiter than the margin of the card, then looking at the card placed on her desk and shifting from the card in her hand, to the other card, helped to improve her vision when practicing in another way failed. This practice helped her for awhile, but that which helped her most to bring about temporary normal vision was the practice of the universal swing.

The patient still reports her progress. After a short period of palming, which is practiced several times each day, she always does the universal swing and emphasizes the fact that it helps her more than anything else.

She told me that at first her husband had been afraid to ride with her after she had removed her glasses and had warned her not to attempt driving without putting them on. He was not opposed to the Bates treatment, but he feared an accident. Now he no longer doubts her ability to see better without the use of glasses, and helps to give her the **sun treatment** every day with the sun glass, which I suggested might be of benefit during the treatment.

Recently I had an unfavorable report of the condition of her eyes. There had been no sun for a few days and she was depressed. I assured her that her depression would disappear when the sun shone again. Practicing the universal swing often, whenever she had the opportunity, relieved her of tension and strain and her vision became normal again.

Encouragement helped, and I believe that she will not need much further advice or instruction from me, because she drives her car with perfect ease. She sees the center of the road coming toward her from the distance and as it comes close, she enjoys seeing it pass under the car. Instead of suffering her usual headache after driving an automobile as she did when she wore her glasses, she feels better after driving. She said that when she learned to see things moving to avoid the stare, her focus for the distance was changed and she could not wear her glasses again even if she wanted to, because they no longer suited her.

Another case, a woman age forty-eight, had worn glasses for more than fourteen years for myopia and headaches. She feared the strong light of the sun because it caused great pain in her eyes. I could not encourage her to practice the Universal Swing until I had first placed her in the sun with her eyes closed, and focused the sun's rays on her closed eyelids with the sun glass. This gave her instant relief. She complained that at all times while she kept her eyes open, they felt tightened up. This was true with her glasses on as well as off. After the use of the sun glass for more than ten minutes I placed her before a window and instructed her to look at the distant houses and other objects. She said that everything appeared blurred to her and that it made her eyes ache all the more while swinging. I knew that she was not practicing it correctly, so I had her sit in a chair and directed her to keep her eyes closed for awhile. While conversing with her, I discovered that palming caused more tension and strain, so I did not encourage it.

**There are many patients who are not benefited by palming, so we change the course of treatment for such patients and they are cured by other means.**

The vision of this patient was 5/200 with the right eye and 5/50 with the left. When the patient covered her left eye, she stared fully a minute with her right eye, in order to see the largest letter of the test card at five feet. **Directing her to count two with her eyes closed, then opening her right eye just long enough to count one as she looked at the test card, then closing her eyes and counting two,** the vision of her right eye improved to 5/50, the same as that of her left eye.

I then placed her in the sun again and used the sun-glass on her closed eyelids for about ten minutes. The expression of her face was entirely changed. Her forehead, which was all lines from tension, became smooth and the corners of her mouth were drawn upward instead of downward.

After the sun treatment, we started the universal swing again while standing by an open window. Off in the distance, an American flag was waving gently with the breeze. She noticed that the flagstaff moved or appeared to move with the movement of her body, head and eyes. The window, shade-cord, curtains, and a chair placed directly in front of her, all seemed to move opposite. This swinging was kept up for fifteen minutes, and immediately afterward in a bright light she read the white letters on the black test card ten feet away. Her vision improved to 10/10 reading with both eyes.

I treated her every day for a week and when she left me on the last day, she said that she had found blinking a help and felt that she must **blink to keep the eyes relaxed**, but she believed as I did, that the **universal swing** was what really cured her.

She assured me that her friends would have to swing with her, if she noticed at any time that they caused her to strain.

Left eye covered with eye patch.  
+ Eyes open - Shift on a letter on the eyechart while counting to one.  
+ Eyes closed - count to two.  
+ Eyes open - shift on the letter and count to one.  
+ Repeat.

Swing left and right in front of an open window. See distant objects (flag, building) move in the same direction with the movement of the body, head, eyes and see the close object (window) move opposite the body, head, eyes.

## Announcement

(Original Natural Eyesight Improvement Teacher Training Courses, Movies)

Because of the increased demand for the Bates Method in California, Emily C. Lierman, assistant to Dr. W. H. Bates for fourteen years and also manager of the Central Fixation Publishing Company of New York City, has opened an office at 609 South Grand Avenue, Los Angeles, California, where she is treating patients. Mrs. Lierman is also giving courses of instruction to those who desire to cure imperfect sight by the Bates method. At the completion of the course, the student receives a certificate authorizing him or her to improve defective vision by treatment without glasses.

Mrs. Lierman is delivering lectures throughout California and is showing **moving pictures** which illustrate the Bates Method of curing imperfect sight.

## Hypermetropic Astigmatism

By Dr. H. M. Peppard

Last fall a young man presented himself to me for examination complaining of **headache, nervousness, insomnia and eyestrain**. He had previously had a **nervous breakdown** and said he felt as if he were going to have another.

This statement was apparently correct if general appearances can be considered as an indication. The eyes were bulging with a dry, glassy appearance and the upper lid markedly retracted.

The eye examination revealed a **very hard eyeball** with 1.25 diopters of **hyperopia** with 2.50 diopters of **astigmatism** with the axis 180°. Glasses had been worn but gave little relief. The visual acuity was 20/50 for both eyes and the same in each eye.

Treatment by the Bates Method was started on August fourth. **Palming, swinging, blinking, flashing and reading of diamond type** was used. The flashing was especially beneficial.

On August 27<sup>th</sup>, the eyes were again tested. Visual acuity was 20/15 for both eyes, 20/15 in the right, and 20/20 in the left. The hyperopia or farsightedness was not present and the astigmatism was decreased to 1.00 diopter. A few more treatments relieved the remainder of the astigmatism and the vision improved to 20/15 in each eye.

With the improvement in vision, the general symptoms cleared up. He became able to sleep, was free from headaches and was not so nervous.

The eyes felt comfortable and his entire facial expression was changed from the relaxation around the eyes. The eyes no longer were starey, but bright and moist and the blinking frequent and easy. Six months later the eyes were in perfect condition and the patient no longer feared a nervous breakdown.

Dr. Harold M. Peppard wrote the book; 'Sight Without Glasses'

Read Aldous Huxley's book: 'The Art of Seeing' along with Peppard's book. Books have a few old methods that need updating, changing but 95% of the information in the books consist effective Natural Vision Improvement treatments.

## An Experiment With Simultaneous Retinoscopy

By W. H. Bates, M.D.

By simultaneous retinoscopy is meant the use of the retinoscope while the patient is using his eyes for distant or near vision.

In order to obtain accurate results by simultaneous retinoscopy, a patient was seated in a chair which was placed about ten feet from the Snellen test card. To the right, to the left, and above the Snellen test card was a blank, dark gray surface. An examination was made with the retinoscope which was held about six feet from the eyes of the patient. While the patient was looking at a blank surface without trying to see, and the retinoscope was used at the same time, it was demonstrated that there was no myopic refraction manifest. The eyes were normal and the patient was able to see with perfect sight.

When the patient moved his eyes quickly from side to side and no effort was made to see, it was demonstrated by simultaneous retinoscopy that no myopic refraction was produced. After shifting from one point to another, closing and opening the eyes and seeing the letters in flashes, the patient's vision improved. By repetition the flashes of improved vision became more frequent and lasted longer, until finally the patient became conscious of a permanent improvement.

Shifting has proved a very valuable method of improving the sight, not only in myopia, but also in all other eye troubles. When the eyes shift to the left, they are stationary for an appreciable length of time, before they can look to the right. When they are stationary, they may stare or strain sufficiently to lower the vision. In order to become myopic while shifting, it is necessary to strain sufficiently to change the shape of the eyeball.

### Circular and Elliptical Shifting Swing

**Circular or elliptical shifting** may be all that is necessary to prevent the eye from staring or making an effort.

When the eyes shift to the left and move in the orbit of a circle or an ellipse, the movement is continuous, and the eyes do not have time to stop before they look to the right. Two areas may be regarded alternately. One part of the background above and to the right of the test card may be regarded with normal sight. Use this area as a point of departure which may be seen for part of a minute or longer. Then shift to the lower left hand corner of the test card and quickly back again to the point of departure. This should be done in one second or less.

When regarding the plain background, the eyes are relaxed or at rest and have normal sight. Shift rapidly downwards to the lower left hand corner of the card and back again to the upper area of the background. In this way shifting may be practiced with benefit. When one can regard the point of departure with normal vision, the eyes become normal temporarily in flashes.

A benefit to the sight comes in flashes at first, although simultaneous retinoscopy indicates that the eye may be, at the same

### Practice shifting

Shift on the white paper on the top right area of the card for part of a minute. Blink and relax. Then, shift rapidly down to the bottom left white area of the card, then back to the top within a second or less. Looking at the white area relaxes the mind, eyes because there is nothing to see, no effort to see=no strain, no blur. As the eyes shift on the white areas of the card the vision and letters become clear. Look at the letters and shift on them.

time, continuously normal. The flashes become more and more frequent and continue for a longer time. (When looking at a blank page, wall... the eyes are relaxed, vision clear because there is not any effort to see, no strain, not trying to see anything.

## Announcement

Dr. H.M. Peppard, of 71 Park Avenue, is a representative of Dr. Bates and is qualified to improve or cure imperfect sight by the Bates method.

Office hours - 9:30 to 6:00 Telephone Caledonia 4694

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JUNE, 1927

### Demonstrate

(Walking, Movement and Oppositional Movement)

#### That the eyes can be used correctly or incorrectly when walking.

Many people have complained that after walking a short distance slowly, easily and without any special effort, they become nervous, tired and their eyes feel the symptoms and consequences of strain. When they were taught the correct way to use their eyes while walking, the symptoms of fatigue or strain disappeared.

The facts can be demonstrated with the aid of a straight line on the floor or the seam in the carpet.

#### Wrong Way

Stand with the right foot to the right of the line and the left foot to the left of the line. Now put your right foot forward and look to the left of the line. Then put your left foot forward and look to the right of the line. When you walk forward, look to the left of the line, when your right foot moves forward. Look to the right of the line when your left foot moves forward. Note that it is difficult to do this longer than a few seconds without uncertainty, discomfort, pain, headache, dizziness or nausea.

#### Right Way

Now practice the right method of walking and using the eyes. When the right foot moves forward, look to the right; and when the left foot moves forward look to the left. Note that the straight line seems to sway in the direction opposite to the movement of the eyes and foot, i.e., when the eyes and foot move to the right, the line seems to move to the left. When the eyes and foot move to the left, the line seems to move to the right. Note that this is done easily, without any hesitation or discomfort.

When you walk, you can imagine that you are looking at the right foot as you step forward with that foot. When you step forward with the left foot, you can imagine that you are looking at your left foot. This can be done in a slow walk or quite rapidly while running straight ahead or in a circle.

Correct method of walking and using the eyes:  
 +Right foot moves forward, look to the right.  
 +Left foot moves forward, look to the left.  
 +The line sways in the opposite direction the eyes and foot move to.

## Astigmatism

By W. H. Bates, M.D.

The study of astigmatism is important because of its frequency and because so many serious diseases of the eye are preceded by astigmatism.

### Definitions

The normal eye is spherical in shape and all the meridians are of the same curvature. The curvature of the cornea is like that of a segment of a sphere; but when astigmatism is present, it is said to be lop-sided; that is, one principal meridian of the curvature is more convex than the meridian at right angles to it. With an instrument called the ophthalmometer, it is possible to measure all the meridians of the curvature of the cornea.

Astigmatism may be simple hypermetropic, simple myopic, compound hypermetropic, compound myopic, mixed or irregular.

+In **Simple Hypermetropic Astigmatism**, one principal meridian of the cornea has a normal curvature, while the meridian at right angles to it is flatter than all the other meridians.

+In **Simple Myopic Astigmatism** one principal meridian of the cornea has a normal curvature, while the meridian at right angles to it is more convex than all the other meridians.

+In **Compound hypermetropic Astigmatism**, the two principal meridians are flatter than the meridians of the normal eyes, one being flatter than the other.

+In **Compound Myopic Astigmatism**, the two principal meridians are more convex than a normal meridian, one being more convex than the other.

+In **Mixed Astigmatism**, one of the principal meridians is flatter than a meridian of the normal eye, while the other principal meridian is more convex than a meridian of the normal eye.

+In **Irregular Astigmatism**, the meridians of the curvature of the cornea are so malformed that no glasses can correct it. This form of astigmatism is usually caused by the contraction of scar tissue, which has formed on the cornea after the healing of a corneal ulcer.

## Occurrence

Astigmatism occurs frequently and is usually combined with hypermetropia or myopia.

I have investigated the facts of the occurrence of astigmatism in new-born children. For the past one hundred years or more, atropine has been used to assist in measuring the astigmatism of the eye. It dilates the pupil and is supposed to paralyze the muscles which change the focus of the eyeball. While young babies were under observation, atropine, of sufficient strength to produce a maximum dilatation of the pupil, was accordingly used. Although the pupils became widely dilated, the ability of the eye to change its focus was not prevented by the atropine. With the aid of the retinoscope, it was found that the form of the eyeball changed from hour to hour or from day to day. My observations showed that the children were born with normal eyes and had no astigmatism, but it was very commonly found to be present as early as a half-hour after birth. The degree and kind of astigmatism varied within very wide limits.

These cases were kept under observation and examined at intervals. In nearly all cases, the eyes were normal and there was no astigmatism present, when they had reached the age of about six years. After attending school a few years, astigmatism was frequently acquired. When those children, who wore glasses for the correction of astigmatism, were examined at the age of twelve years or older, it was found to be still present and increased as they grew older, necessitating stronger glasses. Those children who wore no glasses for the correction of astigmatism, did not have it when they reached the age of twelve or older, which, of course, suggested treatment. Whenever it was possible to remove the glasses of young children, the astigmatism invariably became less or disappeared altogether.

## Symptoms

When a high degree of astigmatism is present, the vision is appreciably lowered. Usually when vertical lines are regarded, they may appear more distinct than horizontal lines, or the reverse may be true. This is, however, not a reliable test because patients with normal vision do not always see vertical or horizontal lines equally well.

Many patients with astigmatism complain of headaches and pain in various parts of the head and eyes. Some patients have said that when their eyes became tired or felt uncomfortable in any way, they could rest them by removing their glasses.

One elderly lady obtained a pair of glasses from an optician for the relief of astigmatism. After wearing them for a few days, she returned complaining that every morning, when she put her glasses on, the pain in her head increased very much, and that, after wearing her glasses for a few hours, the pain was occasionally only partially relieved. The optician remonstrated and told her that she needed to wear her glasses several weeks before her eyes could get used to them. The patient then told him that she had come to have glasses fitted to her eyes, and not her eyes fitted to glasses.

An optician was wearing window-pane glasses for the relief of headaches, and said that glasses were a great help to him. His wife, however, informed her friends that his headaches were much more frequent while wearing the glasses than when he did not use them.

## Cause

**Astigmatism is caused by a mental strain or an effort to see, either consciously or unconsciously.** Patients have demonstrated that astigmatism can be produced by **staring or straining to see**.

The normal eye with normal sight, normal memory or normal imagination has no astigmatism, but **when the normal eye remembers or imagines imperfectly, the retinoscope demonstrates the presence of astigmatism.**

Pain in the eyes and head can always be produced in the normal eye by straining or making an effort to see. Such headaches disappear promptly when relaxation methods are employed.

## Treatment- Astigmatism cures

Astigmatism is caused by a mental strain and can only be cured by complete relief of the strain. Glasses should not be prescribed because they increase mental strain, which is accompanied by an increase in the degree of astigmatism.

To relieve astigmatism, it is necessary for the patient to practice those methods which rest the mind and eyes. Children, when asleep, may acquire in an hour or less a high degree of astigmatism, and the muscles of the face may show a great deal of tension or strain. If this manifest tension can be relieved or corrected altogether, the retinoscope demonstrates that the astigmatism has become less or has disappeared entirely. When astigmatism is present in young babies, it can be lessened by relaxation methods. **The mother can rest the child by swinging it in her arms with a slow, short, easy swing.** In children twelve years of age, and older, astigmatism is often acquired, and can be corrected very promptly by **palming or swinging**.

Sway, Blink, Shift, Central Fixation.

Adults suffering from various forms of astigmatism are benefited by practicing **central fixation**, by **improving their memory and imagination** and by other methods which secure **relaxation**.

## Favorable Conditions

For the correction of astigmatism, we should consider favorable conditions, which promote the best vision. Some patients with astigmatism, perhaps the majority, prefer the illumination to be bright. They can see better in the strong sunlight and the astigmatism becomes less than when the light is dim. Other patients with astigmatism see better, and the astigmatism becomes less or disappears, in a dim light, while it may be very much increased in a bright light.

The distance of the Snellen test card from the eyes is also important. A patient may, at twenty feet, read the card with normal vision, when the astigmatism is not so great. The same patient may read the Snellen test card at ten feet with normal vision and the astigmatism may become worse. Some of these cases are difficult to understand. One patient became worse when the eyes were tested at three feet, but when tested at fifteen feet, the patient read the last line of the Snellen test card and the astigmatism disappeared. Each individual case, in order to obtain the best results from relaxation methods should be tested at a distance which is favorable.

### Central Fixation

The normal eye with normal sight sees with central fixation, i.e., it sees best where it is looking and not so clearly where it is not looking. **The astigmatic eye sees with eccentric fixation, i.e., it sees best where it is not looking. It is important, therefore, that patients with astigmatism consciously practice central fixation until it becomes an unconscious habit.** (Correct Vision Habit)

For example, one may look at the notch at the top of the large letter "C" of the Snellen test card and observe that the notch is seen best, while all other parts of the letter are seen worse. When one looks at the bottom of the large letter and sees that part best, the top is not seen so clearly. With the use of the retinoscope, it can be observed that the astigmatism has become less or disappeared altogether when this is done correctly.

One may look at the lower left hand corner of a white pillow and see that corner best, while the other corners are not seen so well. The patient should then look at the upper left hand corner of the pillow and see that best and the other corners worse. By looking at each corner of the white pillow in turn, the corner regarded will be seen best while the other corners are not seen so clearly and the vision of the whole pillow will be improved. Not only is the form seen better, but the whiteness is also improved by using central fixation. With the eyes open or closed, the memory of the pillow is also improved. Shift part to part on any area of the pillow - left and right, top and bottom, corner to corner, middle.

### Shifting

**The normal eye with normal sight is constantly shifting from one point to another and does not hold one point longer than a second. It may shift only a short distance, a quarter of an inch or less, and then back again to the point previously regarded.** Patients with astigmatism stare or make an effort to see. When a letter or other object is regarded, they attempt to see the whole letter or object at once, they may concentrate on one point for a continuous period of time, thereby increasing the astigmatism.

### Memory and Imagination

The normal eye has no astigmatism when the memory and imagination are perfect. The memory of a perfect letter "O", with a white center imagined whiter than it really is, can be accomplished easily, promptly, continuously, without effort, pain, or fatigue. The memory of the same letter, with the white center covered over by a gray cloud which blurs it, requires a stare or a strain to see or to remember, and astigmatism is manifest. A letter may be remembered imperfectly for a few seconds, but this is difficult or impossible to do for an appreciable length of time. The gray blur constantly changes and always becomes worse or more blurred when the effort to see or remember increases.

A perfect memory can only be obtained when the sight is perfect. A large area of white (white area of the page) can usually be remembered perfectly because it is seen perfectly. By regarding a white area alternately with the eyes open and closed, the memory is improved and the astigmatism is lessened.

When the memory is improved, the imagination usually improves. Since we can only imagine what we remember, in order to imagine letters or other objects clearly or perfectly, a good memory is necessary.

### Case Report - I

A man, aged sixty, was treated some years ago. At his first visit, he was asked to regard a white pillow resting on a table. He was told to close his eyes and remember it. When he did this, he remembered a black pillow instead of a white pillow, which surprised him very much. By having him see each corner of the pillow in turn, with his eyes open, his vision for the white pillow was improved, and when he closed his eyes he was able to remember a white pillow.

### Case Report - II

A girl, eight years old, had a high degree of astigmatism in each eye. The vision of the right eye was 5/200, one fortieth of normal, while that of the left eye was only 3/200 or one sixty-sixth

**C**

+Shift on the notch on the top of the C. Notice that while looking at the notch it is in the center of the visual field and is seen darkest black, clearest. Other areas of the C are in the peripheral field and are less clear.

+Shift to the bottom of the C. Now the bottom is in the central field and clearest and the top and other areas are less clear. Shift part to part seeing one part clearest at a time.

Shift corner to corner on the pillow and see one corner clearest at a time in the center of the visual field. Shift part to part on any area of the pillow, seeing one part clearest at a time. The central field moves with the eyes from part to part. Do this with the eyes open and in the imagination with eyes closed and notice that shifting on the actual and the mental image maintains the clear visual and mental picture of the pillow.

**O**

Shift on the letter O with eyes open, closed, open and remember, imagine it clear with a pure white center. Improving the memory, imagination improves relaxation and clarity of vision.

Girl reads fine microscopic print clear with shifting and central fixation. Print touching the eyelashes, eyes produce a magnifying, microscope effect.

Microscopic vision for any objects close to the eyes.

of normal. The left eye habitually turned in,—internal squint. The child was very bright and seemed to realize the value of central fixation almost from the beginning. By practicing central fixation and regarding the Snellen test card first at ten feet and later at twenty feet, the vision of each eye improved, so that in about a week the vision was normal in each eye and the left eye became straight permanently.

The patient's near vision was also tested. At ten inches, the usual reading distance for the normal eye, the patient by practice became able to imagine one part best of capital letters and, later on, of smaller letters. In about two weeks, she read diamond type at six inches by central fixation. The retinoscope indicated no astigmatism and no malformation, of any kind, of the eyeball. This young child acquired what may be called **microscopic vision**. In three weeks she became able to read very fine print with the paper in contact with the eyelashes of either eye, and very small objects were seen close to her eyes with the same clearness as they were seen with the aid of a microscope. For example, she could describe red blood corpuscles and white blood corpuscles mounted on a glass slide when held in contact with the eyelashes of either eye. The child was benefited or cured by the practice of central fixation. Although the results were very gratifying, the child received so much attention by exhibiting her ability to see, that I was very much relieved when the family left New York for a distant city taking the prodigy along with them.

## Conical Cornea

The question has often been asked if relaxation treatment benefits conical cornea with its large amount of irregular astigmatism. **The contraction of the superior and inferior oblique muscles** (when tense, functioning abnormally) **squeezes the eyeball and increases the length of the optic axis.** As a result of this pressure, the back part of the eyeball becomes thinner and bulges backwards with the production of **irregular astigmatism**. The scientific name for this bulging of the back of the eye is "Posterior Staphyloma." Less frequently, the front part of the eye, the cornea, may bulge in the form of a conical mass and is accordingly termed "**conical cornea**."

Since a strain causes the bulging of the back part or the front part of the eyeball, rest or relaxation of the strain should be and is followed by relief.

Conical cornea is a very painful, complicated disease of the eyes. The vision is always lowered and usually continues to grow worse from year to year. In the beginning, simple astigmatism with a clear cornea can usually be demonstrated in these cases. The amount of the astigmatism may be two diopters or less, and the impaired vision may be improved to the normal with a weak astigmatic glass. The bulging of the cornea increases slowly or rapidly and an ulcer appears near the center of the cornea where the parts are more severely inflamed. The astigmatism becomes the irregular type, in which glasses are not able to improve the poor vision to the normal.

A school teacher had been suffering from conical cornea in both eyes. Her vision was only 10/200 in each eye. With strong glasses for compound myopic astigmatism, her vision was improved to 10/50. For a number of years, she had worn glasses which had been made stronger from year to year. Each time that she was tested, stronger glasses were prescribed for the loss of vision during the preceding year. She suffered great pain which was not relieved by the strong glasses. By practicing **palming**, the **variable and universal swings**, the pain was completely relieved, and the vision improved to 10/40 without the use of glasses. The **relaxation treatment** improved her condition, so that she became able to see without glasses better than she had been able to see with them. It is important to realize that the relief from pain was accomplished in about half an hour of treatment and that the benefit was obtained after other methods had failed while she wore glasses.

**The stare or strain to see has been demonstrated to be associated with all diseases of the eyes, and is the cause of all imperfect sight.** When relaxation is obtained, the eyeball may at once become normal in form with normal sight. Anything that is done with an effort to improve the vision is wrong and always fails. The benefit is only temporary when the stare is only relieved temporarily, but it is always a permanent benefit when the eyestrain is continuously relieved.

Shifting, central fixation, relaxation causes the eye muscles to relax, the eye returns to normal shape, conical cornea, astigmatism... are removed.

## Astigmatism

By Emily C. Lierman

During the holidays, a woman came to me for treatment and brought her prescription for glasses with her. She told me frankly that she was doubtful that I could cure the mixed astigmatism with which she had been troubled for so many years and which was getting worse from day to day. She was **seventy years old and had worn glasses for reading and for distance for about twenty years**. During the past few years she had suffered considerable pain in the back of her eyes. The pain was more intense on bright, sunshiny days, and because of the pain and discomfort caused by the light, she always wore a large hat as a protection from the sun and she frequently wore dark glasses.

The copy of her prescription for glasses showed that she had hypermetropia and mixed astigmatism. The vision of her right eye was better than that of the left for the distance, namely 10/50, but all the letters of the card were blurred. The vision of her left eye was 10/70. When she looked at me, she had no wrinkles in her forehead and her eyes were open in a natural way. When she looked at the test card, there immediately appeared more than a half dozen wrinkles in her forehead and her mouth became distorted as she tried to read the letters for me.

I directed her to palm her closed eyes and, instead of telling her to remember a letter of the test card, which is something I usually direct the patient to do while the eyes are closed and covered, I asked her if she had a flower garden. She answered, "Yes." I noticed how nervous she was and promptly proceeded to make her more comfortable by giving her a **foot-stool, and a pillow to rest her elbows while palming**. She said that she could easily remember the different flowers which she

Oblique muscles shown in red. Tension in the Obliques places pressure on/in the eye causing lengthened eye shape, incorrect focus of light rays in the eye, unclear vision, cataracts...

Lady palms and remembers her flowers. Colors, shapes, names of flowers, shifts on the flowers part to part, flower to flower. Vision clear.

Window Test Card

Sway left and right in front of a window and eyechart.

+Sway left and shift quickly on distant objects outside the window.

+Sway right and shift quickly on a letter on the eyechart.

had planted herself and that it was always a pleasure to spend a great deal of her time in the garden watching the flowers grow. I asked her to name the different flowers and also to mention their colors.

We spent about five minutes' time in this way. Then I removed the footstool and cushion and had her stand as I taught her the **universal swing**. **Swaying to the left, she got a glimpse of the tops of buildings from my office window. When she swung to the right, she was told to glance at the test card on the wall ten feet away and to keep up the universal swing all the time.** Her vision improved in less than ten minutes to 10/30. By reading one line of letters and then another, as I directed her to do, **swinging and blinking with each sway of the body**, the vision of both eyes improved to 10/10. After one hour's treatment, the pain in her eyes had disappeared also.

She complained that she might not be able to do as well by herself at home, and was also doubtful whether her astigmatism could actually be cured. I then proceeded to make her sight worse by having her stare as she looked directly at one letter and then another. She soon complained that the pain in her eyes had returned. I felt sorry to think that under my direction she should be so punished. Many times I have heard Dr. Bates say, **"If you know how to make your sight worse, you will then know how to improve it"**. It has always been a disagreeable task for me to have the patient demonstrate this, as I am sensitive to the pain and discomfort that the patient feels. It is only when a patient complains that she is not receiving much help or that she does not understand how her particular case can be cured, that I cause the patient to make her sight worse by doing the wrong thing.

My patient soon discovered that **staring and straining caused the pain to return and that it lowered her vision for the distance as well as for the near point.**

#### Oppositional Movement

I placed her by a window and directed her to swing with me as my body moved from right to left. Printed signs on the upper parts of buildings in the distance seemed blurred to her before she began to swing. By noticing that the buildings in the distance moved slightly with her, while the window and curtains up close moved rapidly opposite to the movement of her body, her pain and discomfort disappeared. She noticed also that her desire to see things better, which made her forget to blink, prevented her from improving her vision for the test card. Then she conscientiously kept up the blinking as she kept time with the sway of her body. This pleased her and she was satisfied with the treatment.

Ten days later her vision for the test card had improved to 15/10 with each eye, and the black letters on the white card were clear and distinct. I gave her a small Fundamental card to hold in her hand. Immediately, she held the card off as far as her arm would reach. It was interesting to notice how the strain disappeared from her face when she drew the card further away from her eyes. She was told to close her eyes and then draw the fine print card up to about six inches from her eyes. Then, when she opened her eyes and looked at the card, I held her hand in place so that she could not move it further away. In an instant, she drew her head as far back as she could from the card. She said that looking at the letters of the card when it was held so close caused an instant pain in back of her eyes and made her feel nauseated.

I told her to quickly close her eyes and drop the card in her lap and forget about it. In trying so hard to please me, she had produced a terrible strain which made me almost as uncomfortable as it did her. I palmed with her as she again described her garden to me. While her eyes were closed, I placed a test card which was fastened on a stand, five feet from where she was sitting. This card was black with white letters. When all else fails to improve the sight of the patient, this card is my greatest help.

I then told her to follow my finger as I pointed to the first letter of each line down to the bottom of the card. I pointed a half-inch below each letter and told her to look in the direction of my finger tip and not at the letter.

Modern teachers state to look directly at the letters to see them clear. Shift on the letters, relax, blink. Occasionally, take a break and look at, shift on the white spaces to relax the eyes, (without trying to see the letters), then look directly at the letters to see, read them. Reading each letter clearly at five feet produced no strain whatever. As she mentioned each letter, she closed her eyes and remembered it.

Following my directions in this way, she became able to look at the white spaces of the small Fundamental card which she again held in her hand at six inches from her eyes. By shifting and blinking from the small letter "o" of the test card at five feet to the white spaces of the small Fundamental card, she read straight down to the finest print of the Fundamental card, line number fifteen. The change in her face was good to see because all signs of strain had cleared away. When reading the letters on the card, look directly at them, shift, use central fixation. Look at the white area of the card only when resting the eyes, not reading the letters.

She practiced at home for several weeks and then came to me again to hear what I had to say about her good sight. She was able to do without her glasses all the time and did not use them again. She wanted to take more treatment if I thought it was necessary.

I tested her eyes and at fifteen feet she read a strange card, which has small letters to be read with the normal eye at nine feet. This card she read with each eye separately and without any effort or strain.

She told me that she had practiced faithfully every day for more than two hours altogether, and had done as I told her to, which was not to put her glasses on again. She practiced the universal swing almost an hour a day. She said that she enjoyed the universal swing so much that instead of counting to one hundred, which I told her was necessary to do in order to know that she was swinging enough for the improvement of her vision and the relief of strain, she practiced for twenty minutes at a time.

It only took me ten minutes to find out that she no longer needed help from me. I told her, however, that she could be sure of a relapse if at any time she punished her eyes by staring or by not blinking enough.

**Palming and the universal swing** helped her to rest her eyes and to see things moving all the time. **This swing, with the help of the memory of the flowers in her garden, cured my patient.**

**Palm.** Then, look at, shift on the white spaces between sentences on the close fine print card and relax.

**Next** - Look at the distant eyechart and shift on the letters. No effort to see clear. Relax. If a letter remains unclear, look at/shift on a white area of the card to relax the eyes, then return to the letter. Name each letter and close the eyes and remember, imagine the letter clear and shift on it in the mind.

**Look** at the white spaces on the close fine print card again. Then, look at the fine print words and read them clear. Repeat.

#### Announcement

Dr. Bates is pleased to announce that Mrs. E. Reid and Mr. Ian Jardine of Johannesburg, South Africa, have completed a course of instruction under his personal supervision and are qualified to teach the Bates Method of improving imperfect sight without the use

of glasses. Their interest in the Bates method was originally inspired by the benefit Mr. Jardine received in his own case, which led them to travel eleven thousand miles from Johannesburg to New York to study under Dr. Bates personally in order that they might help others who have defective vision.

In the next issue of Better Eyesight will appear Mr. Jardine's account of his case.

## Questions and Answers

Q - Should one practice with fine print by holding it where it can be seen best or at the normal distance?

A - Hold the print at the distance from your eyes at which you see best. Remember not to look directly at the letters, until the eyes have looked at the white spaces first, relaxed, then; look directly at the letters to read them. If done without strain, no squinting: reading fine print closer, at a blurry distance improves the sight.

Q - Is age a factor in the cure of imperfect sight without glasses?

A - Age is not a factor. I have cured hundreds of patients past sixty.

Q - What method is best to relieve the **tension in the back of the neck**?

A - The variable swing. This is described in the September, 1926, number of the Better Eyesight Magazine. See Demonstrate article paragraph 2.

Q - Is the swing apt to cause nystagmus?

A - No, the swing relieves strain, whereas nystagmus is caused by eyestrain.

Q - When taking Dr. Bates' treatment, could one wear glasses for a few hours each day for close work?

A - No, each time you put on your glasses, your progress is retarded.

Q - What causes the lids of the eyes to itch and sometimes become scaly?

A - This is due to strain. Practice relaxation methods all day long, - shifting, blinking and central fixation. Get as much sun treatment as possible.

Q - What causes my vision to improve for a day or two, and then relapse?

A - This is caused by lack of practice and by straining your eyes. When the vision is good, you are relaxed.

Q - In palming, should one close the eyes tightly?

A - No, easily, lazily and naturally at all times.

Q - Why is my vision worse on a rainy or cloudy day than in broad daylight?

A - Because you strain to see on a dark day.

Also: the pupil is larger in dimmer light - the pinhole effect of bright light is not available. If the vision is imperfect, imperfectly focused light rays in the eye and the larger pupil in dimmer light lets in more light rays; more imperfectly focused light rays are on the retina and blur is increased. Practice Natural Eyesight Improvement, Correct Vision Habits - shifting, central fixation, relaxation, switching, memory and imagination at night for clear night vision and vision will be clear in all levels of light.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JULY, 1927

### Demonstrate

**Demonstrate that perfect sight is accomplished when the imagination is good, and that you see only what you imagine you see.**

Take a Snellen test card and hold it at a distance from your eyes at which your sight is fairly good. Look at the white center of the large "O" and compare the whiteness of the center of the "O" with the whiteness of the rest of the card. You may do it readily: but if not, use a screen, that is, a card with a small hole in it. With that card, cover over the black part of the letter "O" and note the white center of the letter which is exposed by the opening in the screen. Remove the screen and observe that there is a change in the appearance of the white, which appears to be a whiter white, when the black part of the letter is exposed. When the black part of the letter is covered with a screen, the center of the "O" is of the same whiteness as the rest of the card. It is, therefore, possible to demonstrate that you do not see the white center of the "O" whiter than the rest of the card, because you are seeing something that is not there. When you see something that is not there, you do not really see it, you only imagine it. The whiter you can imagine the center of the "O," the better becomes the vision for the letter "O," and when the vision of the letter "O" improves, the vision of all the letters on the card improves. The perfect imagination of the white center of the "O" means perfect imagination of the black, because you cannot imagine the white perfectly, without imagining the black perfectly. By practice you may become able to imagine the letter "O" much better than it really is, and when this is accomplished, you become able to actually see unknown letters.

Contrast between black and white, halos of black letters, camera effect and other functions of the eye, brain cause the appearance of the white glow, white center of a letter o appearing bright white.

## The Imperfect Sight Of The Normal Eye

By W. H. Bates, M.D.

**People with normal eyes do not have normal sight all the time.** It is only under favorable conditions that vision is continuously good or perfect. Some individuals may have normal sight at twenty feet, but not at a nearer or more distant point. Normal sight at twenty feet does not mean normal sight at ten feet, five feet, or nearer, or at twenty-five feet or further. What may be favorable conditions for one person may not be favorable for everybody or for the same person at different times. Frequently imperfect sight may be found to a greater or lesser degree in cases of squint or strabismus, although the optic nerve, retina, and other parts of the eye may be normal. Such cases are suffering from eyestrain and are cured by relaxation treatment.

The amount blindness produced by an unconscious or conscious strain is very variable. The amount of vision lost may be one-tenth of normal sight, or it may occasionally be six-tenths, nine-tenths. I have found the vision to be lowered to no perception of light, in eyes which had no organic changes in the retina, optic nerve, choroid or other parts of the eyeball. The pupil did not react to light by direct illumination. These cases were all cured by relaxation methods.

The imperfect sight of the normal eye is similar in its manifestations to **amblyopia ex anopsia** in which no organic changes are present to account for the poor vision. Not all cases of **squint** have imperfect sight of the eye which turns in or out habitually or continuously. Usually the eye with the poor vision is turned, but there are many exceptions, for example, the eye with good vision may be the one that is turned. Sometimes the vision may alternate and would then be good in the eye that is straight and poor in the eye which turns. After relaxation treatment has improved the sight of both eyes to normal, the eyes may become permanently straight, but it is always true that the patient can produce a relapse by a conscious or an unconscious effort, and as a result, the vision in one or both eyes is always lowered.

A woman, age sixty, recently came to me for treatment. She had worn glasses for more than thirty years to improve her vision not only for the distance, but also for reading. Bifocals made her eyes feel worse and produced a greater amount of discomfort than any other glasses. Three years ago, the vision of the right eye was good and she could read a newspaper with the aid of her glasses. With the left eye she could not read, even with glasses. Her vision for distant objects was imperfect and was not improved by glasses. Sometimes the right eye had good vision, while the vision of the left eye was much less. On other occasions the vision of the left eye was good, while that of the right eye was very imperfect. She had been to see a great many eye specialists for treatment, but none had been able to fit her properly with glasses for distance or for reading. All these eye specialists admitted that they did not know the cause of her imperfect sight. She was fitted with many pairs of eyeglasses, no two of which were alike. Some doctors prescribed eye drops, others internal medicines. With the hope of giving her relief from the agony of pain which she suffered, various serums were administered. Some eye specialists treated her for cataract, others for diseases of the retina, optic nerve and other parts of the interior of the eyeball.

She was suffering from eyestrain or a mental strain, which produced many different kinds of errors of refraction. When she strained her eyes, she produced a malformation of the eyeballs which caused imperfect sight. This condition had been temporarily improved by glasses. In a few days or a week, however, the glasses had caused her great discomfort and made her sight worse.

I made a very careful ophthalmological examination, but found no disease in any part of the eye. Her eyes were normal, although the vision was imperfect.

I emphasized the fact that if she wished to be cured permanently, it was necessary for her to discard her glasses and not put them on again for any purpose whatever. This she consented to do.

The use of her memory and imagination helped to improve her vision. **She committed to memory the various letters of the Snellen test card** and with her eyes open, regarding each letter, her memory or imagination of the letters was good. When she closed her eyes, not only could she remember or imagine each letter perfectly black, but she also could remember the size of the letter, its location, its white center and the white halo which surrounded it. With her eyes closed, she could remember the whiteness of the spaces between the lines much better than she could imagine it with her eyes open. With the aid of the retinoscope, I observed that when she imagined normal vision with her eyes open, there was no myopia, hypermetropia, nor astigmatism present. When she suffered pain, however, the shape of the eyeball was changed and her vision always became worse. This patient demonstrated that the normal eye is always normal when the memory or imagination is good. When the memory or imagination is imperfect, the vision of the normal eye is always imperfect.

A Snellen test card with a large letter "C" at the top was placed about fifteen feet in front of her. To one side was placed another Snellen test card, with a large letter "L" at the top. She was unable to distinguish the large letter "L" with either eye, but she could read all the letters on the "C" card, including the bottom line, with the aid of her memory and imagination. With a little encouragement, she became able to imagine the large "L" blacker than the large "C," although she could not distinguish the "L." In a few minutes, when she imagined the "L" blacker than the big "C," she became able to distinguish it. By the same methods she became able with the help of her memory and imagination, to imagine smaller letters on the large "L" card to be as black as letters of the same size on the "C" card. By improving the blackness of the small letters on the large "L" card, and imagining them perfectly black alternately with her eyes open and closed, the small letters became visible and she was able to distinguish them.

When this patient looked fixedly at, or centered her gaze upon one part of a large letter at six inches, she found that it was difficult, and it required an effort to keep her eyes open, and to look intently at one point. She also found that by looking at other letters and trying to see them all at once, or by making an effort to see all the letters of one word simultaneously, her vision was lowered. When she was advised to look at the white spaces between the lines, she said that it was a rest and that the white spaces seemed whiter, and the black letters then seemed blacker. When she avoided looking directly at the letters, she became able to read some of the large print.

(Modern teachers state; to look directly at the print to see/read it; central fixation. It is ok to first look at the white spaces, away from the print, to relax the eyes, mind before looking at the print.)

After she had imagined the white spaces between the lines to be whiter than they really were, it was possible for her to imagine the thin, white line. This line is imagined along the bottom of a line of letters where the black of the letters meets the white of the white space. She was not always sure that she looked at the white spaces, although she planned to do so. When she tried to read and felt pain or discomfort, she was unconsciously looking at the letters; but when she looked at the white spaces and succeeded in avoiding the letters, she felt no discomfort and she was able to read almost continuously without being conscious that she was looking at the letters. When she practiced relaxation methods, did not stare, did not strain nor try to see, her vision became normal.

## Military Story

A young man, aged 18, desired to enter the **Naval Academy at Annapolis**. He had already passed a satisfactory physical and scholastic examination, but he had failed to pass the eye test. The vision of each eye was one-half of the normal. By practicing the swing, and with the aid of his memory and imagination, his vision became 15/10, or better than normal. His great difficulty was that, although he read this test card with each eye with normal vision, 20/20, the day before his eye test, he became so nervous just as soon as he met the eye doctor that he practically went blind.

The eye doctor was sorry and wished to help him as much as possible and so referred him to me. I found, with the aid of the retinoscope, that the vision of each eye was normal when he looked at a blank wall without trying to see, but just as soon as he regarded the Snellen test card at twenty feet, he began to strain, his eyes became myopic, and his vision very imperfect.

It is seldom that one sees eyes as perfect as were the eyes of this young man. When his vision was good, the weakest glasses made his sight worse. The problem seemed to be to **improve, not only his eyes but his mental strain**, so that he would not lose the control of his eyes just by glancing at the Snellen test card.

A Snellen test card was placed at thirty feet, another card was placed almost directly in line at ten feet, so that it covered the distant Snellen test card. When the patient swayed from side to side, the near card appeared to move in the direction opposite to the movement of his body, while the more distant card seemed to move with the movement of his body. When he moved to the right, the 10 line letters on the near card seemed to move opposite, while the 30 line letters on the distant card moved with the movement of his body. Later he obtained normal vision at twenty feet by the same method.

The following is a letter which I received from the patient:

June 16, 1927

Dear Dr. Bates:

I am happy to inform you that I passed my eye examination to the U. S. Naval Academy and I am now a member of the student body, a merry, meek "plebe."

Dr. Bates, I wish that there were some adequate way I could express my appreciation to you for your assistance and kind advice which not only has given me better eyesight, but has made possible a thing that I had long desired and which will equip me with a wonderful education and a wonderful career in life. In the absence of proper words and phrases, I will just say that you have my heartfelt thanks and the thanks and gratitude of my parents. I deeply enjoyed the work and I am now deeply enjoying my eyesight.

I have tried to apply your methods of relaxation to not only eyesight, but to every other organ of my body and to my different endeavors. The Naval Academy is perhaps as difficult a school from which to graduate as any in the United States, and it is by eliminating the unimportant and the wrong methods of doing that a fellow can stay here. I think that the difference between success and failure can be in the way an individual does his work. I have learned my lesson about the evils of concentration and strain, and I hope to apply my lesson.

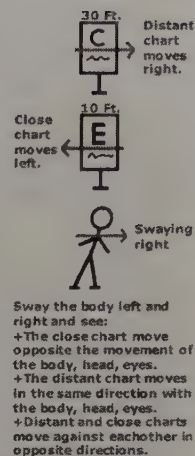

If at any time it is in my power to render the least service to you, I will be very pleased to do it. Again I thank you and wish you the best of luck and success in the work you are doing.

Sincerely yours, (No name written)

The sway, oppositional movement rests, relaxes the mind, body, eyes, gets the eyes shifting, left and right brain hemispheres activated, integrated and vision clear.

Seeing objects at different distances move against each other in opposite directions when swaying helps people with very blurry vision distinguish/see objects individually and clear. Improves mind/eyes ability to look at, shift on one object at a time. Central fixation.

It is normal for the clarity of vision to fluctuate. Practice the Bates method to keep vision at better than 20/20 and temporary fluctuations will be minor, not noticed. Avoid glasses. Glasses prevent the vision's natural return to clarity.

## STORIES FROM THE CLINIC

## Eyestrain

By Emily C. Lierman

A girl who had worn glasses for more than twenty years, came to me to have her eyes tested after she had been to an oculist and had had her glasses changed. She complained of constant pain in her eyes. Her vision with each eye separately was 15/30, or one-half of normal vision. While reading the letters of the Snellen test card at fifteen feet, she did not blink, until she began to read the letters on the line that should be read at thirty feet. Then her eyes began to water and she complained that they burned like fire.

## Palming

I told her to sit down and close her eyes to rest them. I made her comfortable with a cushion for her elbows while palming, and a foot-stool to raise her feet from the floor. I asked her to remember something perfectly and then let her mind drift to something else. She was told that it was necessary to remember pleasant things; that otherwise her mind would be under a strain and her vision would not improve. Like many patients, she began to question me about what the mind had to do with the eyes. She was told that when the mind is under a strain, all other parts of the body are also under a strain. When the mind is relaxed, the eyes are also relaxed and things are seen without effort or strain. Mind strain is always associated with eye-strain. You cannot affect one without affecting the other.

While she was palming, the patient described many colors that came to her mind. She described their combinations in making beautiful paintings and fancy draperies. After palming for more than ten minutes, I told her to remove her hands from her eyes, to stand and sway her body from left to right. By glancing at only one letter of the test card at a time and then looking away, she read 15/10 or better than normal vision in ordinary daylight.

I tested her sight for the reading of fine print, and she read it with perfect ease, first at four inches and then at ten inches.

When I saw her again, she had discarded her glasses, her pain was gone, and her eyes no longer troubled her.

Palm and remember things perfectly, let the mind drift from one positive thought to another, pleasant things. See objects in color, clear, details. Shift on objects in the mind.

Face the eyechart and sway left and right while shifting quickly, 'fraction of a second' on one letter at a time. Look away after each letter to avoid effort to see, to keep relaxation.

Fine print read clear at 4 and 10 inches.

Fig. 42. Palming

This is one of the most effective methods of obtaining relaxation of all the sensory nerves.

Fig. 45

Fig. 1.—Patient with absolute glaucoma of the right eye. He had suffered agonizing pain for six months and had no perception of light. He was photographed when testing the tension of his eyeball, which he found to be perfectly hard.

Fig. 2.—The patient is palming and remembering a perfectly black period. After half an hour the eyeball became soft, the pain ceased, and the patient became able to see the light. After three years there was no return of the glaucoma.

Fig. 46. Strabismic Amblyopia Relieved by Palming and the Memory of Black

While the patient was exhibiting in her surgical history the method of relieving pain by palming and the memory of black, another member of the family, who was suffering from rigid cataracts, came in, and having heard what was being said, immediately got to the practice and was cured. The youngest sister developed severe pain in her head and eyes, and did not obtain any relief until she also practiced palming and the memory of black.

### Fundamentals By W. H. Bates, M. D.

- 1 - Glasses discarded permanently.
- 2 - Central fixation is seeing best where you are looking.
- 3 - Favorable conditions: Light may be bright or dim. The distance of the print from the eyes, where seen best, also varies with people.
- 4 - Shifting: With normal sight the eyes are moving all the time.
- 5 - Swinging: When the eyes move slowly or rapidly from side to side, stationary objects appear to move in the opposite direction.
- 6 - Long swing: Stand with the feet about one foot apart, turn the body to the right—at the same time lifting the left foot. Do not move the head or eyes or pay any attention to the apparent movement of stationary objects. Now place the left heel on the floor, turn the body to the left, raising the heel of the right foot. Alternate.
- 7 - Drifting swing: When using this method, one pays no attention to the clearness of stationary objects, which appear to be moving. The eyes move from point to point slowly, easily, or lazily, so that the stare or strain may be avoided.
- 8 - Variable swing: Hold the forefinger of one hand six inches from the right eye and about the same distance to the right, look straight ahead and move the head a short distance from side to side. The finger appears to move.
- 9 - Stationary objects moving: By moving the head and eyes a short distance from side to side, being sure to blink, one can imagine stationary objects to be moving.
- 10 - Memory: Improving the memory of letters and other objects improves the vision for everything.
- 11 - Imagination: We see only what we think we see, or what we imagine. We can only imagine what we remember.
- 12 - Rest: All cases of imperfect sight are improved by closing the eyes and resting them.
- 13 - Palming: The closed eyes may be covered by the palm of one or both hands.
14. Blinking: The normal eye blinks, or closes or opens very frequently.
- 15 - Mental pictures: As long as one is awake one has all kinds of memories of mental pictures. If these pictures are remembered easily, perfectly, the vision is benefited.

#2 - Central fixation - Place the object the eyes are looking at in the center of the visual field.  
 #5 and 9 - Oppositional movement.  
 #6 - Long swing - The head, eyes do move with the body, in synchronization, at the same time, in the same direction.  
 #8 - This can also be done with the finger 6 inches in front of the face/nose, between the left and right eyes.  
 #10, 11, 15 Memory, imagination, remembering, imagining objects, mental pictures clear.  
 #13 - Palming and other activities, correct eye functions listed above and in this book are described with diagrams on <http://www.cleareyesight.info> and in the E-Book: Do it Yourself - Natural Eyesight Improvement.

### Seven Truths of Normal Sight

- 1—Normal Sight can always be demonstrated in the normal eye, but only under favorable condition.
- 2—Central Fixation: The letter or part of the letter regarded is always seen best.
- 3—Shifting: The point regarded changes rapidly and continuously.
- 4—Swinging: When the shifting is slow, the letters appear to move from side to side, or in other directions, with a pendulum-like motion.
- 5—Memory is perfect. The color and background of the letters, or other objects seen, are remembered perfectly, instantaneously and continuously.
- 6—Imagination is good. One may even see the white part of letters whiter than it really is, while the black is not altered by distance, illumination, size, or form, of the letters.
- 7—Rest or relaxation of the eye and mind is perfect and can always be demonstrated.  
 When one of these seven fundamentals is perfect, all are perfect.

## Glaucoma

A man, age fifty-nine, came to me recently to find out whether anything could be done to prevent blindness of his right eye. He had only perception of light in his left eye. In 1918, both eyes had been operated upon for glaucoma. The left eye had had no sight before the operation. The vision of the right eye with the test card was normal. After closing his eyes and palming for five minutes or longer, he noticed that objects about the room looked clearer. I placed him in a chair with his back to the light and gave him the booklet with **microscopic type**, a small **diamond type card** and a small **Fundamentals card for practice**. He held the booklet of microscopic type about ten inches from his eyes. Above this was placed the "Seven Truths of Normal Sight," by W. H. Bates in diamond type, and then above this the Fundamental card, exposing sentences up to paragraph four which explains shifting.

I told the patient to look at any white space of the microscopic type, to close his eyes and remember it for an instant; then to open his eyes and look at a white space of the diamond type card. He was advised to quickly close his eyes again and remember the white space for an instant, then to open his eyes and look at the type of the Fundamental card.

I encouraged him to shift, blink and remember the white spaces of the different types as he flashed them. Then, after closing his eyes for an instant, he became able to see the "F" of the word "Fundamentals" blacker than the rest of the word. I explained that this was called central fixation, and that seeing best where he was looking helped him to see the whole word more clearly. While he practiced in this way for ten or fifteen minutes, I watched him carefully so that he did not strain when looking at the fine type, and

advised him to look only at the white spaces. Look at the white spaces first, to relax the eyes, then: look directly at the letters to see/read the letters.

He read one sentence after another, stopping to mention a period, a semi-colon or a colon. I explained that it was necessary for him to notice all little details, because it would improve his memory as well as his sight. Remembering the white spaces of fine type, then of larger type, then of type a little larger than newspaper type, helped him to see type smaller than ordinary reading type. In an hour, after much encouragement, my patient read all the fifteen sentences of the Fundamental card. He became very much excited, because, while he had received help from others for distant vision, he had not been able to read such fine type for many years, even with glasses.

Practice shifting on, remembering, imagining a letter on the cards clear with the eyes open, closed, open.

Eyes open: Shift on a letter and remember, imagine it clear.

Eyes closed: Shift on the letter in the mind and remember, imagine it is clear.

Eyes open: Shift on the letter again and continue to remember, imagine it clear.

I then decided to attempt to improve the left eye in which he had no sight. One of the small Fundamental cards has white letters on a black background and is an exact copy of a larger test card. After he had palmed for some time, I told him to be sure to keep his right eye covered, so that he could not see with it. (Both eyes open and close together when wearing the Eyepatch. Do not close or open only one eye. Use the patch.)

Then asked him to open his left eye and tell me if he could see what I was holding in my hand about ten inches from his eyes. He answered: "I see everything dark with the exception of something that looks like a small white 'E' on the top of the black card." This was correct. He then became very much excited, and as a result of this strain, the vision left him.

I instructed him to practice all that he possibly could with the fine print cards and also with the distant cards and to write me in a week's time. In his report he said: "Standing with my back to the window, the sky overcast with fog or clouds, I can see the T O Z of the small test card at a distance of two feet, one letter at a time, with my left eye. I can also see the end of my thumb holding the card at the lower left corner. The sight of my left eye is almost as good at night, under a shaded lamp with an 80 watt light. You may be sure I am continuing the exercises daily, as you advised."

Man improves vision in his left eye, the eye with less clear vision.

+Shift on letters on the large distant card and close fine print card with the left eye. Blink.

+Shift on a letter with the eye open and remember, imagine it clear, +Then: repeat in the imagination with the eye closed.

+Open, repeat.

+Look at and remember, imagine the white spaces between sentences, in and around letters pure, bright white with the eye open, closed, open.

+Then look at the black print and read it clear.

+Last: practice with the right eye, then left again, then both eyes together.

Mrs. Edith Reid and Mr. Jardine of Johannesburg, South Africa, who are qualified to improve defective vision by the Bates Method have sent in the following reports of their respective cases.

### Report of Mrs. Edith Reid

I had got to a stage when I had to wear glasses for all close work. My distant vision was poor and the light worried me terribly. The glare from the sun used to give me dreadful headaches so much so that when out sketching, I always wore two pairs of glasses, blue ones over my ordinary glasses. Even then I used to get home tired out with a horrible headache. My memory was shocking.

When worried or excited, I used to almost forget my own name.

I had heard of Dr. Bates' method being practiced by Ms. Quail so I thought I would try and see if anything could be done for me. When tested I could read only 10/20 on the Snellen test card, and on the small card, paragraph 2. I was not able to see that there were any letters on the last line at all. It was proved that the trouble was all caused by strain. I was taught how to **use my eyes without strain and to rest them by swinging and getting things to move everywhere.**

I discarded my glasses, and at my second treatment, I was able to read the entire test card at ten feet, 10/10. My near vision also improved. I was then taught to **sun my eyes daily** and to **rest them by palming**. Each day not only my sight but also my general health improved in every way.

One day I was traveling in the train with my husband and he came across a paragraph in the newspaper which he wanted me to read so he gave it to me saying: "Read that." I took the paper, never realizing what I was doing. When I had read about half of the paragraph, I realized that I was reading small print. I became very excited and shouted, "Goodness, I am able to read small print." I suppose people in the compartment must have thought that I was crazy, but it did not worry me. I felt only so very grateful that I wanted to tell everybody about Dr. Bates' wonderful method.

Palming, memory, imagination, mental pictures

I was taught how to perfect my memory of a letter, by looking at a letter and then remembering it with my eyes closed, and to remember something that was pleasant to me. This I found very difficult, but by this time I had absolute faith in the method, so used to try to remember mental pictures, at odd moments, all day long. After practicing this for several weeks, I found that I was able to palm and call up a picture of any place I had known and to paint a picture from memory.

Reading small print in an artificial light still bothered me, but I have been very fortunate to have been able to come to America and be treated by Dr. Bates himself. Now I am able to read diamond type and newspaper print by electric light.

I have had my glasses on only once since I was told to discard them. I was making a black velvet cushion at night and was afraid that I might strain my eyes so I put my glasses on. I found everything looked misty, so I took them off and very carefully wiped them, but things were still misty. I then washed them but things continued to look misty, and only then did I realize that my **eyes had become so well that the glasses were too strong for my improved vision.** From the time I began wearing glasses, my sight rapidly became worse, not only my near sight, but my distant vision as well. I always thought it wrong that when one reaches so called "middle age," one's sight should fail. **Now it has been proved that through this method, one can live to be one hundred years old, not wear glasses and yet have perfect sight.** It is impossible for me to express in words my deep gratitude to Dr. Bates for his discovery of the cure of Imperfect Sight Without the Use of Glasses.

## Report of Mr. Ian Jardine

My dear Dr. Bates:

At the age of about eleven years I was completely blind for about five weeks during a severe illness. My vision slowly returned until about three months after, when it was apparently normal again.

A year after this, my eyes began to trouble me and glasses were prescribed. The prescription was made up wrongly, the left lens being placed before the right eye and vice versa. This was discovered only six months' later on a re-examination because of continuous headaches.

The next twelve years were a succession of examinations by the best eye specialists in South Africa, each one meaning stronger glasses with no relief of pain.

About eighteen months ago, I was assured by two prominent eye specialists in Johannesburg that I had an incurable eye disease and that nothing could possibly be done to save my sight, which they said would fail altogether in the near future. Unknown to me, my father had been told on my first examination that this disease was present in the eyes and would slowly spread, but so slowly that they did not expect blindness until the age of 50 or 60. My field of vision was so limited that I could see only what was immediately in front of me, and at night I was almost totally blind.

Faced with this cheerful outlook, I was granted a holiday during which time I heard of Dr. Bates' method of Eye Education, being practiced by Ms. Quail of Capetown.

At the first lesson my glasses were removed and I was told that they were never to be put on again. This was a great shock as all the doctors had greatly stressed the fact that the glasses were to be left off only during sleep. Then I was taught the swing, in other words to see or imagine everything moving. The pain immediately disappeared, so that I walked home in the seventh heaven of delight led by Ms. Reid who helped me a great deal during the treatment. However, a day or two later, on the persuasion of well meaning friends, I wore my glasses. The old pain immediately returned, but I put up with it thinking that perhaps my eyes had to get used to the strong lenses again. Fortunately, next day was lesson day. Ms. Quail informed me that it was to be either glasses and no cure, or no glasses and a cure. As I had in the long run, nothing to lose by leaving off the glasses, I determined never to have them near me again and to try out this new system quite fairly. **Then I was shown how to sun my eyes by letting the rays of the sun fall on the closed eyelids, while moving the head gently from side to side.** This seemed a strange thing to do, as previously I had worn blue glasses to shield the eyes from strong light.

By practicing the **universal swing**, i.e., imagining everything to be swinging gently from side to side,—noticing the movement of all things when walking,—pedestrians bobbing up and down, vehicles hurrying by, buildings and pavements gliding past as one moved forward,—**spending a good part of each day in the sun**, improved the vision so remarkably that three months after the first treatment, I was able to resume my profession,—auditing,—most times having to work under dim artificial light, but always without glasses and without discomfort.

However, I am afraid that during those three months, I suffered many weak moments, becoming rather despondent and fearful at times when the sight did not seem so good as it was the day before, or when things still looked blurred, but I can look back on those unhappy days,—real enough at the time,—with a smile and without the least doubt for the future. My eyes are now entirely free from disease and the sight is normal.

**Sunning - face the sun, eyes closed, move the head side to side.**

## Questions And Answers

Q - a - How often should the sunglass be used?

b - How long on the closed lids before using it on the eyeballs themselves?

c - Can one use the sunglass on one's own eyes?

A - a - Daily for two or three minutes. (Two or three seconds at a time. Minutes are too long. Applying the sunglass for only a few seconds prevents burning the eye.)

b - Usually for several weeks on the closed lids before using it on the eyeballs themselves, although the length of time varies with each individual case.

c - Some people can, but it is rather difficult and awkward to do.

Q - My neck gets very cramped in the back and becomes very painful. Is there any way of relieving this?

A - Practice the long swing, variable swing and circular swing. (The directions for all these swings have appeared in previous numbers of Better Eyesight.)

Q - Since I have taken off my glasses I find it almost impossible to not half close my eyes to see better. (Squinting)

A - Partly closing your eyes brings on a strain which increases your imperfect sight. It is a bad thing to do because it injures your eyes.

Q - My vision, after practice with the test card is good, but I cannot sustain it. What means can I use to have continuous vision?

A - Acquire a continuous habit of imagining stationary objects to be moving easily, until it becomes an unconscious habit.

Q - If I blink everything becomes blurred. How can I overcome this?

A - Practice blinking, slowly, easily, without a conscious effort as much as you possibly can. Shift

Q - I have myopia and have been practicing your methods. At first, I had very good results, but I now seem to be at a standstill.

How can I continue to progress?

A - There are three things which you can practice. One is blinking, one is palming, and one is the practice of the circular swing, that is, moving the head and eyes in the orbit of a circle. The modern Infinity Swing, Figure Eight is best.

Q - My eyes are so sensitive to light that it is impossible to use the sun treatment. In what way can I use it and avoid headaches and pain which it causes?

A - Sit in the sun with your eyes closed, allowing the sun to shine directly on your closed eyelids, as you move your head slowly from side to side.

Q - I have found blinking and shifting to be of great benefit to me but, although I have been practicing both for six months, it has not become a habit. I still have to practice both consciously. What means can I use to blink and shift normally?

A - Continue to consciously practice blinking and shifting until you acquire the unconscious habit. It is merely the substitution of a good habit for a bad one. Practice with the eyes open before going to sleep. Practice in the imagination with the eyes closed before drifting off to sleep. The conscious and subconscious mind will absorb the correct habits, correct eye function and activate it automatically.

Q - Can one swing objects or letters by moving just the eyes, or must one always move the head or body?

A - It is easier to move the head and body with the eyes.

## SCHOOL NUMBER BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

AUGUST, 1927

### Demonstrate

That glasses lower the vision.

Stand fifteen feet from the Snellen test card and test the vision of each eye without glasses.

Then test the vision of each eye with glasses on, after having worn them for half a hour or longer. Remove the glasses; test the vision again and compare the results. Note that the vision without glasses becomes better, the longer the glasses are left off.

Test the eyes of a person who is very nearsighted. Remove the glasses and test the sight of each eye at five feet, nearer or farther, until the distance is found at which the vision is best without glasses. Now test the vision for five minutes at this distance, which is the optimum distance, or the distance at which the vision is best. For example, near-sighted people see best when the print is held a foot or nearer to the eyes. If the eyes see best at six inches, the optimum distance is six inches; but if the distance at which the eyes see best is thirty to forty inches, the optimum distance is then thirty or forty inches.

In near-sightedness, glasses always lower the vision at the optimum distance. The same is true in far-sightedness or astigmatism. For example, a near-sighted person may have an optimum distance of six inches. If glasses are worn, the vision is never as good at six inches as it is without them. This demonstrates that glasses lower the vision at six inches, or the optimum distance in this case. In far-sightedness without glasses, the optimum distance, at which objects are seen best, may be ten feet or further. If glasses are worn and the sight is improved at the nearer point, the vision without glasses at the optimum distance becomes worse.

## The Prevention Of Imperfect Sight In School Children

By W.H. Bates, M.D.

Eye education has been proved to be effective in preventing and improving defective vision in school children.

A negative proposition is one that cannot be proved. You cannot say that any methods, recommended for benefiting the vision of school children, prevent imperfect sight and the use of glasses, because the vision of the children might remain good if no measures were employed for their benefit. However, a positive proposition is something that can be proved to be true. For example, if the eyesight of school children is imperfect, eye education always improves the imperfect sight.

A **SNELLEN TEST CARD** was used for more than twenty years as a means of preventing and improving imperfect sight. This card was placed on the wall of the classroom. Every day, while sitting quietly in their seats, the children were encouraged to read the Snellen test card, with each eye separately, covering one eye in such a way as to avoid pressure on the eyeball. This required only a few minutes and did not interfere with the regular schoolwork. The results obtained from this simple practice were very gratifying.

In one high school, a teacher became interested in eye education and, with the consent of the principal, introduced the method into her own classes. She made it a rule not to treat a child, unless he were willing to remove his glasses permanently. Besides curing children, she cured many teachers who were wearing glasses. Each teacher, who had learned the method, surreptitiously cured all the children in her classes who had imperfect sight. In this way an endless chain was formed. After a number of years, the method became known to the parents of the children and also to a number of physicians. As a result of this publicity, the teachers were asked to stop treating the children by the use of eye education. It is difficult to understand why eye education should be condemned when voice education is encouraged and teachers are appointed to educate children for the relief of stammering. Many teachers of voice culture have found that their pupils were suffering from nerve tension, because of eyestrain. When the eyestrain was relieved, the nerve tension disappeared and the stammering was corrected.

**PALMING.** Resting the eyes by palming is one of the best methods we have for obtaining relaxation and improved vision.

Many children suffer from headaches, eyestrain and fatigue. When the eyes are closed and covered with the palms of both hands, it is possible to obtain rest and relaxation of the nerves of the eyes and of the body generally, provided the palming is done properly. Palming is successful when all light is excluded and no light or colors are imagined. When a child with normal eyes and normal sight enters a dark closet, where all light is excluded, no light is seen or imagined. (This sentence means: no light is seen through the fingers/hands and no colors are seen on the black field of the closed eyes. Modern teachers say that it is ok if a little light gets through the fingers. The hands must not be pressed hard against the face, and do not touch the eyes. Also; moving colors are seen sometimes when the eyes are first closed, often when the mind and/or eyes are under strain, tension or after looking at a bright light. Do not worry about the colors. Just relax, think pleasant thoughts and these colors will fade. Remembering, imagining different colors, colored objects, scenery when palming is beneficial. See the Color Breathing Relaxation Chart in the book; Do It

Yourself – Natural Eyesight Improvement. The same is true when the normal eye practices palming; no light is seen or imagined. Black is imagined easily, without strain; but any effort that is made to see black is wrong. Most children are fond of pleasant memories and when they palm, they usually think of pleasant things, which help them to palm successfully. When school children learn by experience that palming is a benefit to their sight, headaches, nervousness, or other disagreeable symptoms, they will practice palming very frequently without being encouraged to do so.

**CENTRAL FIXATION.** Those children, who have trouble in obtaining relaxation by palming, are benefited by practicing central fixation, which means seeing the point regarded best, and other parts not so clearly. For example, in remembering a pet dog, one child liked to think of his curly tail, then of his long silky ears, or of the black spots on his legs. When conditions are favorable, that is, when the light in a classroom is neither too bright nor too dim, eyestrain is less manifest. The children are more relaxed and become able to palm more successfully.

**SWAYING.** Another method used is to have the children stand with their feet about one foot apart and sway the whole body from side to side. When this is practiced, the stare, strain or effort to see is prevented and the vision is always benefited.

**FINE PRINT.** When school children are able to read fine print at the distance from their eyes at which they see it best, the eyestrain is relieved as fine print cannot be read with an effort. **The distance where fine print is seen best varies with people.** All children should not be encouraged to see fine print at the same distance from their eyes.

With practice, relaxation, people can see fine print up close to the eyes, even seeing it in a 'microscopic view' close to the eyelashes of one eye at a time. Bates teaches to switch back and forth, close and far, shifting on the fine print up close and a distant object with both eyes, then one eye at a time, then both together again. Switching on two fine print cards at close distances about 3 inches to 1 foot apart also improves close vision. See the 'correct vision habits card' in our other book.

**SHIFTING.** When the eyes are normal, they are completely at rest and when they are at rest, they are always moving, which prevents the stare or strain. When looking at an object, do not try to see all parts of that object equally well, at once. That is, when you look at the back of a chair, you see that part best, and the seat and legs not so clearly. But do not hold the point regarded longer than a second. Remember to blink, as you shift rapidly to the seat and then to the legs of the chair, seeing each part best, in turn. When the eyes stare and an effort is made to see, the vision is always lowered.

Shift part to part on the chair and see each part clear, one small part at a time. The eyes, 'center of the visual field' may be on a part for only a fraction of second before shifting to a new part - during that fraction of a second that part is in the center of the visual field and is seen clearest.

**SWINGING.** When the eyes move slowly or rapidly from side to side, stationary objects, which are not regarded, appear to move in the opposite direction. Like many things, the swing can be done wrongly as well as rightly. When done wrongly, the blackness of the letters and the whiteness of the spaces, between the lines of the Snellen test card, become imperfect. When the swing is imperfect, the vision also becomes imperfect. To be able to practice the swing perfectly is a great help to the sight of school children. The teacher can direct the children to stand beside their desks while swaying from side to side. The pupils can notice that the desks in front of them, the blackboard, and the Snellen test card are all moving in the direction opposite to the movement of their bodies. When the pupils look out of the window, the curtain cord and other parts of the window will appear to move in the opposite direction, while more distant objects, buildings, trees or mountains, will appear to move in the same direction as they sway. When walking straight ahead, children can notice that the floor appears to move towards them. If the children are conscious of the movement of the floor and other objects, the stare and strain is prevented, and the vision is always improved; but if the pupils do not notice the movement of objects when they, themselves, move, they are apt to strain and the vision is always lowered.

When pupils imagine the Snellen test card to be moving from side to side, the imagination of the black letters or of the white spaces is improved. **If the head and eyes are moved an inch or less from side to side, the Snellen test card and the letters on it will also appear to move an inch or less.** With the aid of the short swing, it is possible for the pupil to remember, imagine or see each and all the letters of the Snellen test card correctly and continuously, but if the letters do not move, an effort is soon manifest. The children then find that trying to see a letter, or part of a letter, stationary, requires a strain and is difficult. It seems strange, although it is true, that to fail to have perfect sight requires an effort, and hard work. In other words, perfect sight can only come easily, and without effort; while imperfect sight is obtained with much discomfort and effort.

**BLINKING.** The normal eye, with normal sight blinks frequently, easily and rapidly, without effort or strain. If children do not blink frequently, but stare and try to see things with the eyes open continuously, the vision is always impaired. At first the child should be reminded to blink consciously but it soon becomes an **unconscious habit** and the vision is improved. (Correct Vision Habit)

**MEMORY AND IMAGINATION.** The scholarship of children is affected by their memory of mental pictures. Measures which have been practiced by many school teachers for the preservation or the improvement of memory are quite numerous. When children learn how to remember some things perfectly, the memory of other things is improved. With a perfect memory, it is also possible to have a perfect imagination. We see only what we think we see, or what we imagine. When the imagination is perfect, the sight is perfect and when the sight is perfect, the memory is perfect. These and other clinical observations have demonstrated the truth that **sight is largely mental. Perfect sight or imperfect sight is due to the condition of the mind.** When the mind is healthy and active, perfect memory can usually be demonstrated, but when the mind has lost its efficiency, the memory becomes impaired. The memory is benefited by those methods which bring rest and relaxation. With the eyes closed, the memory is usually better than it is with the eyes open.

After regarding a letter which is seen imperfectly at a distance of ten feet or nearer, the student can remember the same letter more perfectly by closing his eyes. When the child can remember a perfect letter at ten feet with the eyes open, he soon becomes able to see and remember the same letter at eleven feet, and can gradually increase the distance to fifteen or twenty feet. Practicing the sway, alternately with the eyes open and with the eyes closed, is a benefit to the memory and the sight, because when the eyes are moving, a stare, strain or effort to see is more or less prevented.

When a line of letters on a Snellen test card can be read easily, it is usually possible to read some of the letters on the line below.

Look at, shift on a unclear letter on the eyechart. Close the eyes and shift on the letter in the mind and remember, imagine it clear. Open the eyes, shift on the letter, close the eyes and repeat. When the letter is clear, practice at farther distances. Do the reverse for close vision improvement.

However, if this cannot be done, have the child come closer, until all the letters of the bottom line are seen at a distance of five or ten feet. When a child cannot read all the letters on the 10 line at ten feet, he may be able to remember or imagine all the letters of the 10 line, with the eyes closed, better than with them open. By alternately closing the eyes for part of a minute or longer, and then opening them for only a moment, the vision improves.

A child may be able to see the first letter on the bottom line of the card when he is told what the letter is. Although he may not know what the second or third letters are, he may be able to actually see them and other letters on the bottom line by improving the vision of the first letter so that it is imagined perfectly. When the memory and imagination of the first letter is quite perfect, or sufficiently perfect to be distinguished, the eye becomes normal and the other letters are really seen and not imagined.

A child, at some previous time, may have had an inflammation or disease of the eyeball, which caused his imperfect sight. For example, a scar, sufficiently thick to interfere materially with the vision, may have formed over the front part of the eyeball. A perfect memory or imagination of a letter with the eyes closed, always lessens the opacity, and the vision is always improved, at least temporarily. By repetition, the short periods of improved vision occur more frequently and last more continuously.

The imagination is very important, much more so than many of us believe. Some people think imagination is simply another word for illusion. However, it is possible to imagine correctly as well as to imagine incorrectly. Some people can imagine a truth perfectly, but react differently when they imagine things imperfectly.

A girl, twelve years of age, had unusually good vision. She was able to read the 10 line of a strange card, which she had never seen before, at fifty feet. She said that she could look directly at one letter of the 10 line and see it continuously, but when her eyes were observed while she was doing this, it was found that she shifted almost continuously.

Her memory was also unusually good. She was the only member of the party who could remember the names of the officers on the different steamers on which she had traveled to Europe. She remembered the numbers of her staterooms, as well as the numbers of the staterooms of the other members of the party. However, when she imagined all these things incorrectly, she felt decidedly uncomfortable, but when she remembered to imagined things perfectly, she felt no discomfort.

At school, her teachers considered her stupid, because she disliked some of her studies and devoted no time to those lessons. Her poor scholarship disappointed her family very much. She was very unhappy and decided to prove what she could do. About a week before the examinations, she read through her Latin textbook and remembered it perfectly. She also read her other textbooks and remembered what they contained. She asked to be examined in all her subjects and much to the surprise of the teachers, she passed the examinations with unusually high honors.

A student obtained high grades in history by creating movie pictures in his mind of every story, event he read in his history book. He stole the history book for the next school year, read it during summer vacation (without pressure from teachers to hurry and get a perfect grade). In September he entered that class and earned all A's on his history papers.

## School Children

By Emily C. Lierman

### Davey

Davey, eight years old, was very near-sighted, and the glasses he was wearing, made him nervous and irritable. His father had been told about the Bates Method and what could be done to restore perfect sight without wearing glasses. Davey's father brought the boy to me, although he was skeptical and his mother was even more so. I could tell by the little boy's attitude toward me that the Bates Method had been much discussed in the home circle, and that I was considered a sort of mystic worker.

The first question Davey asked me was, "What are you going to do to me?"

I answered, "I am not going to do anything to you, but I will try to do a whole lot for you. I will help you to get rid of your thick glasses that I am sure you don't like."

His answer was, "O, yes, I would like my glasses if I could see out of them. Father said that if you don't help me, he will try to find other glasses that will help."

I let the little fellow talk for a while, because I thought it would help me to understand him better. I told him I was especially interested in children and that it was always my delight to give school children better sight. I said I would not interfere with him, if glasses were what he wanted most. He said that he was afraid to play baseball or other games which might not only break his glasses, but perhaps hurt his eyes.

I tested his vision with his glasses on, and found that at ten feet from the regulation test card, he could see only black smudges on the white, but no letters. Then I placed the card six feet away. All he could see at that distance was the letter on the top of the card, seen normally at two hundred feet. I then had him take off his glasses to see what he could read without them. He could not see anything at all on the card. I asked him to follow me to the window and to look in the distance and tell me what he could see. To the right of me, about one hundred feet away, there was a sign. The letters of this sign appeared to be about three feet square. One word of the sign had four letters. The first letter was straight and the last was curved, and had an opening to the right. I explained this to Davey, as I told him to look in the direction in which I was pointing, and then to a small card with fine print that I had given him to hold. I told him to read what he could of the fine print. He read it at two inches from his eyes. Under my direction, he alternately followed my finger as I pointed to the fine print and then to the building sign. He told me he could not see anything in the distance.

Davey felt very uncomfortable because of his poor sight and became rather restless. I told him to hold the fine print card closer, and not to read the print this time, but to look only at the white spaces between the sentences, and to blink often. He shifted from the white spaces of the fine print to the sign in the distance, watching my finger as I pointed, first to the near point and then to the distance. Suddenly, he got a flash of the first letter of the first word on the sign. This practice was continued for twenty minutes, and then we had a rest period. Davey sat comfortably in a chair and palmed his eyes. Children are very apt to become bored with anything that takes time and patience, and I know that Davey had little patience with anything regarding his eyes.

I asked him questions about his school work, and what subjects he liked best. He said he just loved arithmetic. I asked his father to give him an example to do while he palmed. The little fellow thought this was great fun, and without hesitation he gave his father the correct answer for each example. This gave Davey a rest period of fifteen minutes. His mother remarked that this was the first time she had ever noticed him sit quietly for so long a time.

### Long Swing and Sway

Davey was then shown how to swing, by moving his body slowly from left to right, and getting only a glimpse of the letters on the card, at six feet. When he looked longer than an instant at the card, he leaned forward and strained to see better, but failed each time. **When he learned not to stare, but to shift and blink while he swayed, his vision improved to 6/50.** We returned to the window. I told him to shift from the white spaces of the fine print, which I held close to his eyes, then to the distant sign, and he became able to read all of the sign without any difficulty.

Much had been accomplished in one treatment and both parents were grateful. Davey was given a card with instructions for home practice. He returned three days each week for further treatment. Every time he visited me, I placed the test card one foot further away. Eight weeks after his first treatment, he read all of the test card letters at ten feet. This was accomplished by reading fine print close to his eyes, then swinging and shifting as he read one letter of the card at a time.

This boy has sent other school children to me as well as a school teacher with progressive myopia, who practiced faithfully until she was cured. Every week, she sent me a report about her eye treatment and the progress she made. Her pupils noticed that she had discarded her glasses, and after school hours she invited some of them, who had trouble with their eyes, to practice the Bates Method with her. In eight weeks' time, her vision became normal, and all her pupils, with the exception of three, are improving their vision without the use of glasses.

Practice switching from a fine print card to a distant sign outside a open window;  
+Shift on letters on the fine print card.  
+Switch to the distant sign and shift on letters on the sign.  
+Switch back to the fine print. Repeat shifting on letters on the close fine print card and distant sign.

Sway in front of the eyechart, shift on letters, blink and read a fine print card, then switch to the distant eyechart and shift on the letters, then back to the fine print. Repeat.

Swing in front of the eyechart and glance at letters.

### Esther

Esther, aged seven, first came to me in January, 1927, to be relieved of **squint**. She had worn glasses since she was three years of age for the relief of squint in the right eye. Her parents noticed, after she had worn glasses a short time, that she was more nervous than before. Later, they were much concerned because she acquired bad habits, such as holding her head to one side instead of straight, especially while studying and reading her school lessons. Her glasses were then changed. It was thought that wrong glasses had been prescribed because she still kept her head to one side as before, and her nervousness became more pronounced. The parents were told that in time the squint would be corrected if Esther wore her glasses all the time.

The squint continued to get worse instead of better, so the parents brought her to me. The vision of her right eye was 10/15, but in order to read the letters of the test card, she had to turn her head so that it almost rested on her right shoulder. Her left vision was 15/15 and she read the letters of the card in a normal position. I tested her right eye again, placing the card up close. She turned her head just as much to one side as she did when the card was placed ten feet away. I asked her mother to hold the child's head straight, and again told Esther to tell me what the letters were. I held the test card two feet away while she covered her left eye. She said everything was all dark, and she could see nothing.

It did not take me long to find out that Esther was a bright child, and that she would willingly do anything for the benefit of her poor eye. She said to me, "It is too bad that my sister should have two good eyes and that I should have only one good one." I encouraged her to follow my directions closely and I told her if she continued to do so and practiced as often as she should at home, that we would then try to correct the vision of the poor eye.

#### Palming, Memory, Imagination

I found her to be quite an artist. When her eyes were covered, I asked her if she could remember a drawing of some kind. "Oh, yes," she answered, "while my eyes are closed and covered I can imagine that I am drawing your picture."

I said, "All right, you keep on imagining that you are drawing my picture and later on I will let you sit at my desk and draw a picture of me." We talked about pleasant things for five or ten minutes while she had her eyes covered.

#### Long Swing

I then taught her to swing her body from left to right, glancing for only a second at the test card, and then looking away to her left. I purposely avoided having her swing to the right, because she had the desire, while reading or trying to see more clearly to always rest her head on the right shoulder. I drew her mother's attention to the fact that, **as she swung, both eyes moved in the same direction as her body was moving.** When she stopped blinking, which I had encouraged her to do rhythmically with the swing, her right eye turned in and her head also turned to one side.

After she had practiced swinging for a little while, I noticed that she gaped a few times, which meant that she was straining. It is good for parents to notice this, in helping the child practice for the relief of squint, and to stop all practice with the exception of closing the eyes to rest them.

When practicing the Long Swing for the first few times, for some people with squint, (wandering/crossed eyes) the eye may wander, cross. This occurs due to the Long Swings function of removing different types, multiple layers of strain from the mind, eyes, eye muscles and correcting left and right brain hemisphere function, integration and eye movement. A negative thought, emotion, experience may have initially caused the first strain, slight blur, then the person worries about the blur, starts squinting, staring and this causes a additional, different strain: worry, eye muscle, eyestrain. Blur is increased, wandering/crossed eye occurs or increases and more worry, strain, staring, squinting and trying to force the eye straight occurs=a third type of strain. The Long swing and other Bates activities will remove all these strains and reverse the condition back to normal - straight eyes, clear vision.

Esther palmed again for a little while and then I showed her some celluloid toy animals and asked her to name each one of them. She named each one correctly with the exception of the buffalo, so I did not use that one for her case. If a child under treatment for squint is asked to tell things in

Left eye covered. Using the right (squint) eye. Mom touches a familiar toy and the girl names it.

detail, the child must be familiar with the objects. While she again covered her eyes to rest them, I placed animals on the floor five feet away from where she was sitting. I told her mother to touch each animal and have Esther name them. Out of eight animals, she named three incorrectly. They were among the last ones she tried to see. We then noticed that her head turned to one side in order to see them. All this time her left eye was covered.

Then I had Esther sit at my desk and asked her to draw my picture. The drawing was quite well done for a little girl of her age. She kept her head straight while drawing. When strain is relieved, the symptoms of imperfect sight are relieved also. She enjoyed drawing, therefore it did not produce a strain. When she was asked to read the test card letters, she strained in order to see them and the condition of her eyes became worse.

Esther was encouraged to do something that she liked at every treatment, such as writing figures from one to ten, or drawing a line without using a ruler. At the first attempt, the lines were very crooked and the figures not straight.

**Swinging and palming, practiced several times daily, soon improved the right eye to normal.** At the last visit, her head remained straight and the squint had entirely disappeared.

The vision of her right eye became better than normal, as far as reading the test card was concerned. She read the bottom line at twelve feet and seven inches. This line is read by the normal eye at nine feet. She did equally as well with the left eye, which, of course, had normal vision in the beginning.

To be sure that the child was entirely relieved of squint, I told her to look at my right eye, then at my left eye, then to my chin and other parts of my face as I pointed with my finger to each part. She followed me with both eyes moving and her head perfectly straight and as yet she has had no relapse.

## THE USE OF THE SUN GLASS

In using the sun glass, it is well to accustom the eyes of the patient to the strong light by having him sit in the sun with his eyes closed, and at the same time he should slowly move his head from side to side, in order to avoid discomfort from the heat. Enough light shines through the eyolids to cause some people a great deal of discomfort at first, but after a few hours' exposure in this way, they become able to gradually open their eyes to some extent without squinting the lids. When this stage is reached, one can focus, with the aid of the sun glass, the light on the closed eyolids, which at first is very disagreeable. When the patient becomes able to open the eyes, he is directed to look as far down as possible, and in this way the pupil is protected by the lower lid. Then by gently lifting the upper lid, only the white part of the eye is exposed, while the sun's rays strike directly upon this part of the eyeball. The sun glass may then be used on the white part of the eye. Care should be taken to move the glass from side to side quickly. The length of time devoted to focusing the light on the white part of the eye is never longer than a few seconds. After such a treatment the patient almost immediately becomes able to open his eyes widely in the light.

## A School Teacher's Report

June 12, 1927

As a teacher of Speech Improvement I have found that some of the exercises that are used by Dr. Bates in the correction of poor vision are very helpful in the treatment of stammering. Those who stammer are invariably nervous, and the palming and swaying exercises calm the nerves and help the children to speak more quietly and slowly and therefore without stammering. In all cases where I have introduced the swaying in my stammering classes, the result has been a greater calmness both in reading and speaking and I believe that in this age of nerve tension, relaxation exercises are a boon even for children of school age.

Poor speech and poor sight often go together and it is a happy circumstance that Dr. Bates has devised exercises that will help both defects at the same time. An outstanding case of a child suffering both from defective speech and very poor eyesight was a little Italian boy who was in one of my stammering classes. I asked him to read a sentence from the blackboard and he immediately bent his body away over to one side and stretched his neck as far forward as he could, straining to see the letters. I directed him to cover his eyes for a few minutes and then to sway for a while. He soon found that he could see much better and that he could read without stammering. He was very backward in reading and spelling. Although in the second year of school, he did not even know

the names of all the letters of the alphabet. I believe that this was largely due to his poor vision and that the stammering came as he became aware of his inability to keep up with the rest of his class. During the short time that he was with me, his speech and sight greatly improved.

Posture is another thing that may be improved by the swaying exercise. Ordinarily, when you ask a child to stand in good posture he will place his feet close together like an Egyptian statue. In the sway, he is shown that by putting his feet apart he has a broader base for standing and more ease and comfort for moving. I hope that some day we may be able to bring all these beneficial exercises to all the children in the schools who need them.

## Announcement

We wish to call to the attention of our readers, the Bound Volume of the "Better Eyesight Magazine" from July, 1926, to June, 1927. This contains articles written by W.H. Bates, M. D., on his discoveries, relative to the cure of Imperfect Sight by Treatment Without Glasses.

Each month, he discusses in detail the causes and treatment of various phases of imperfect sight. Instructions and suggestions for home treatment are also given.

Another article, demonstrating the various truths of Dr. Bates' discoveries, proves most beneficial in this treatment.

There is also a Question and Answer column in which questions submitted by subscribers and interested readers are answered by Dr. Bates.

We have only one hundred copies and advise all those who wish to keep the book as reference to send in an early order.

Bound in green leather and embossed in gold.

\$3.00 prepaid.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

SEPTEMBER, 1927

### Demonstrate

(Sunning and use of the Sunglass)

#### 1 - That sun treatment is an immediate benefit to many diseases of the eye.

Before the treatment, take a record of your best vision of the Snellen test card with both eyes together and each eye separately without glasses. Then sit in the sun with your eyes closed, slowly moving your head a short distance from side to side, and allowing the sun to shine directly on your closed eyelids. Forget about your eyes; just think of something pleasant and let your mind drift from one pleasant thought to another. Before opening your eyes, palm for a few minutes. Then test your vision of the test card and note the improvement. Get as much sun treatment as you possibly can, one, two, three or more hours daily.

When the sun is not shining, substitute a strong electric light. A 1,000 watt electric light is preferable, but requires special wiring. However, a 250 watt or 300 watt light can be used with benefit, and does not require special wiring. Sit about six inches from the light, or as near as you can without discomfort from the heat, allowing it to shine on your closed eyelids as in the sun treatment.

#### 2 - That the strong light of the sun focused on the sclera, or white part of the eyeball, with the sun glass, also improves the vision.

After the eyes have become accustomed to the sunlight with the eyes closed, focus the light of the sun on the closed eyelids with the sun glass. Move the glass rapidly from side to side while doing this for a few minutes. Then have the patient open his eyes and look as far down as possible, and in this way, the pupil is protected by the lower lid. Gently lift the upper lid so that only the white part of the eye is exposed, as the sun's rays fall directly upon this part of the eyeball. The sun glass may now be used on the white part of the eye for a few seconds, moving it quickly from side to side and in various directions. Notice that after the use of the sun glass, the vision is improved.

## Blindness

By W. H. Bates, M.D.

When the normal eye has normal sight, it is constantly moving. When it has imperfect sight or is partially or completely blind, it is always seeing stationary objects or letters stationary, or is making an effort to do so. These two truths suggest the prevention or cure of blindness.

When adults, school children and others are taught to imagine stationary objects to be always moving, the vision always improves.\*

To do the wrong thing, namely, to imagine or try to imagine all objects stationary, very soon becomes associated with an effort or strain. Why is it a strain to have imperfect sight? Because it is impossible for the eyes or mind to concentrate. To regard a point continuously is difficult or impossible. Trying to do it, is trying to do the impossible; and trying to do the impossible is a strain.

All cases of imperfect sight or blindness are caused by a strain. When the strain is relieved or corrected by closing the eyes and resting them, the vision always improves.

It can be demonstrated that blindness from conical cornea, ulceration and inflammation of the cornea can, in all cases, be made

worse by straining or making an effort to see. This is a truth, and, therefore, has no exceptions.

\*(Stationary objects appear to move when the eyes move, shift. - Oppositional movement.)

+Stare at a object - Do not shift on it - The object does not move, no oppositional movement is seen - Strain and blur results.

+Look at the object - Shift on the object part to part - The object appears to move in the opposite direction the eyes shift to:

Oppositional Movement- Relaxation and clear vision.

## Glaucoma

**GLAUCOMA** is a serious disease of the eyes. In most cases, the eyeball becomes hard and this hardness can be felt by pressing lightly on the closed eyelid with the fingers. For the relief of this hardness, various operations have been performed to promote the escape of the fluids of the eyes. These operations have not always been satisfactory. Many cases of glaucoma have been relieved for a limited period of time, but sooner or later, become totally blind. When blindness occurs, operations have usually failed to restore the sight.

**CAUSE.** (and symptoms) The theory that the disease is caused by a hardening of the eyeball is incorrect, because we find cases of glaucoma in which the eyeball is not increased in hardness, and there are cases of hardening of the eyeball in which there is no glaucoma. The normal eye may be hardened temporarily by conscious eyestrain. The cause of glaucoma, in all cases, is eyestrain, and may be demonstrated as follows: When the normal eye has normal sight, it is not under a strain. When a letter or an object is remembered or imagined imperfectly, the eyeball at once becomes hard. Other symptoms of glaucoma may also be observed, namely, one may see rainbow colors around the flame of a lighted candle. Another symptom is the pulsation of one or more of the retinal arteries. In most cases, severe pain has been observed.

Patients with glaucoma usually suffer not only in ways already mentioned, but also from other symptoms just as severe and more difficult to describe. Glaucoma affects the nervous system and produces not only extreme depression but disturbances in all the nerves and organs of the body.

**TREATMENT.** When a person is suffering from glaucoma, the memory of perfect sight produces complete relaxation with a temporary cure of the glaucoma.

Too many cases of absolute glaucoma, totally blind with no perception of light, suffering an agony of pain with great tension or hardness of the eyeball, have been enucleated. Acute, absolute glaucoma may have no manifest organic changes in the eyes. **When the eyestrain is relieved by palming, swinging and the use of a perfect memory or imagination, these cases have always obtained temporary relief at once and a permanent relief by the continuation of the relaxation treatment.**

## Cataract

In **CATARACT**, the pupil instead of being black becomes a light gray or some other color, due to the opacity of the focusing lens of the eye, which is just behind the colored part of the eye, the iris. Rays of light which enter the eye pass through this lens and are focused on the back part of the eye, the retina. When the lens becomes opaque, the rays of light from different objects do not pass through the lens and the vision is consequently lowered and the patient becomes more or less blind. If one places six sheets of glass, one on top of the other, so that all are parallel, it is possible to see through them. If, however, one or more of the glasses form an angle or is not parallel with the rest, the layers of glass become cloudy, just like the layers which form the crystalline lens in cataract.

**CAUSE.** Cataract has been observed for many thousands of years by the people of India, Egypt, and in various countries of Europe. The theories of the cause of cataract are very numerous. The lens is composed of transparent layers. When these layers are squeezed or when the eyeball is squeezed, the layers which form the lens become cloudy or opaque. It is a very simple experiment to take the eye of some animal which has just been slaughtered and to hold it with the tips of the fingers of one hand. By pressing the eyeball, the lens at once becomes cloudy and a white mass, which can be seen twenty feet or further, usually appears in the pupil. With the cloudiness of the lens, there may occur at the same time, a cloudiness in the front part of the eye, the cornea. Just as soon as the pressure is removed from the eyeball, the area of the pupil becomes perfectly clear and the lens becomes perfectly transparent. It is such an easy thing to try and is so convincing that I wish that more ophthalmologists would study it.

**Pressure of the eyeball may come from the contraction of the muscles on the outside of the eye, which are quite capable of keeping up a continuous pressure for many years, without the patient being conscious of it.**

Cataract has been produced in normal eyes by the memory or the imagination of imperfect sight. The memory of imperfect sight produces a strain of the outside muscles of the eyeball, which is accompanied by a contraction of these muscles, and cataract is produced.

Almost any kind of opacity of the lens has been produced by pressure. The area of the pupil may become varicolored, due to the difference in pressure. The strain of the eye or mind which produces cataract is a different kind of strain than that which produces glaucoma. **Every symptom of eye trouble is caused by a separate strain.** The strain which produces near-sightedness is a different kind of strain than that which produces astigmatism or inflammation of the cornea or inflammation of the colored part of the eye, the iris. The strain which produces pain is not the same strain which produces squint. One may practice the strain which produces squint continuously without necessarily producing pain. The strain which produces cataract does not produce pain. Cataract is a disease of the eye which is never accompanied by pain unless the patient with cataract also strains in a way which produces pain. The strain which produces cataract never produces pain.

**TREATMENT. Palming, swinging, sun treatment, and other methods of relaxation treatment\*1 cures cataract because it relieves eyestrain which is the cause of cataract.**  
September 1927

\*1- Described in the book "Perfect Sight Without Glasses," by W.H. Bates, M. D., and previous issues of "Better Eyesight" Magazine.

## Conical Cornea

In **CONICAL CORNEA**, the front part of the eye bulges forward and forms a cone-shaped body. The apex of the cone usually becomes the seat of an ulcer and sooner or later, the vision becomes very much impaired. In advanced cases, the patient suffers very much from pain. Various operations have been performed, but the results have always been unsatisfactory.

**CAUSE.** The cause of conical cornea is eyestrain. The fact has been demonstrated that those measures which cure eyestrain; **palming, swinging, the variable swing**, as described in paragraph 7 of the Fundamental card, and the use of the **memory and imagination,—are a benefit or a cure of conical cornea.**

## Opacity Of The Cornea

The cornea, when healthy, is perfectly transparent and does not interfere with the vision of the colored part of the eye, or pupil, but when the cornea becomes opaque, the opacity may be so dense that the color of the iris cannot be distinguished, and there is no perception of light.

**Cause.** Opacities of the cornea are said to be caused by infections, ulcers or some general disease, but there are many cases which are caused by eyestrain, because when the eyestrain is relieved by relaxation treatment the opacity of the cornea always improves and the vision becomes normal.

### Blindness Cured

**Treatment.** One patient, forty years of age, had been **blind from birth**. The corneas of both eyes were totally opaque, so that it was impossible to see the color of the iris. The patient was helpless on the street and required someone to lead him. **Central fixation, the use of his memory and imagination**, and other methods for the relief of eyestrain were practiced. **The Sun treatment** was especially beneficial. The patient was taught to expose his closed eyelids to the sun for many hours daily.

At the end of a few months' treatment, he became able to recognize people on the street. He was taught the alphabet and the names of the figures. When his knowledge of the letters became perfect, he was able to read the Snellen test card, 20/20. He was also able to read fine print without glasses. After thirty-five years, his friends reported that his eyes were still normal.

Another case was that of a woman, aged seventy-five, who had to be led into the office. She had suffered from inflammation of the cornea of both eyes for many years, and had frequent attacks of ulcers. From time to time, these ulcers would heal, but they always left a scar.

When the patient was first seen, a scar tissue involved the whole cornea, so that one could not distinguish the colored part of the eye. I believe that eyestrain was the only cause of the trouble, because the **sun treatment, palming and swinging**, brought about an improvement so that the cornea became perfectly clear, and the vision of the patient for distant and near objects was normal.

## The Blindness Of Squint Or Amblyopia Ex Anopsia

In cases of **SQUINT**, the vision of the eye which turns either in or out is variable. In many cases, the squinting eye may have normal vision, but in the majority of cases, the vision may be very much lowered, and in rare cases, the squinting eye may be totally blind with no perception of light.

**CAUSE.** There have been many theories proposed to account for the blindness of squint. I have found, however, that the cause of the blindness is due to eyestrain.

**TREATMENT.** The vision of these cases is benefited by relaxation methods - palming, swinging and the use of the memory or the imagination. A letter may be imagined perfectly or imperfectly. When imagined imperfectly, the vision is always lowered. **When imagined perfectly, with the eyes open as well as with the eyes closed, the vision is always improved.** By remembering or imagining a letter, with the eyes closed for half a minute or longer, one becomes able to imagine a letter quite perfectly with the eyes open for a few seconds. Repeat.

**CASE HISTORY.** In one case, a woman, about thirty years of age, was totally blind in the right eye which turned in, although the eye itself was apparently normal. That is to say, there were no opacities in any part of the eye, and the retina and optic nerve were normal.

With both eyes open, the vision was 15/20. By practice, with the aid of her memory and imagination, the vision, with both eyes, soon became normal without glasses, 15/10. Coincident with the improvement of the vision of both eyes together, which meant an improvement in the vision of the left eye, the patient gradually became able to distinguish light in the right or blind eye. In less than two weeks, after daily treatment, the vision of the right eye became normal and the eyes straight.

It seems curious that so many articles have been published on amblyopia (dim-sightedness) ex-anopsia (from lack of education or use of eye) without going further and studying the results of the opposite of ex-anopsia, - relaxation methods of treatment.

## Blindness

By Emily C. Lierman

On March 19, 1927, a woman came to me who was affected with temporary blindness. She was not with me longer than five minutes when I noticed that she was under an intense mental and nervous strain. When I spoke to her, tears welled up in her eyes. Every part of her body was tense and the white parts of her eyes, i.e., the sclera, were blood-shot and she had no desire to keep them open in a natural way.

She told me that she had had trouble with her eyes as long as she could remember. Blocks of blind spots were visible before her eyes at all times; blindness caused by strain. She said she always kept her glasses near her bed so that she could put them on first thing in the morning.

Her sight was better at night than in the daytime. The daylight caused her a great deal of discomfort and pain and most of the time she had a desire to keep her eyelids lowered. When she was wearing her glasses, she felt more depressed than when not wearing them. Her eyes itched and she had rubbed her eyelids until they had become soar. This caused her to be more nervous than ever. **Long periods of daily sun treatment finally cured the itching of her eyelids.**

When I tested her sight with the test card, her right vision was 15/20 but she strained very hard to see the letters, which gave her eyes the appearance of being closed. The vision of the left eye was 15/50 and it caused her pain when she read with it. I encouraged her to palm and while her eyes were closed, I asked her to talk about her loved ones at home. As she told me of some of their habits and how she loved them I noticed her smile for the first time.

She was taught to **stand with her feet one foot apart and sway her body from left to right; flashing the test card letters one at a time.** I reminded her many times to blink her eyes in order to stop the stare, for she stared a great deal. When she finally learned how to **blink while swaying**, her vision improved to 15/15 with each eye separately.

I then had her sit in a chair with her back to the sunlight and gave her the Fundamental card to hold. I asked her what she could read on it. She said she could not read any of the print at all on the card. I told her to shift from the white spaces of the microscopic type, to the white spaces between the lines of the "Seven Truths of Normal Sight," which she held with the Fundamental card; flashing only the white spaces and avoiding the reading of print. This practice was kept up for almost a half-hour and I then suggested that she notice the numbers at the beginning of each sentence of the Fundamental card. Her attention was drawn to the number next to each number. She was told to notice the white spaces of the different sized type as she held it in her hand. (Then look at the period, then the letters). Before her first treatment was over, she read the sentences from number one to number five.

At the beginning of her second treatment she said that the food placed before her at the table was beginning to look like food to her before she ate it. Before, she never knew what she was eating until she tasted it.

**Sun treatment** was kept up regularly every day. This improved her vision for the test card and fine print to normal. I handed her a newspaper and pointed to the smallest type that I could find on the front page. The smallest print was about the size of diamond type. She read this clearly for the first time in her life. During her second treatment, when she held the card in the sunlight, her vision improved for the Fundamentals card to number eight.

After several treatments she told me that her friends were noticing how much younger she looked. The sclera of both eyes was clearing up and she was smiling most of the time. She became able to read all of the Fundamental card at reading distance, ten or twelve inches from her eyes and sometimes closer. The blind spots and black spots that had appeared before her eyes for many years, also disappeared. She was told to remain in the sun for hours at a time, keeping her eyes closed while her head moved slowly from side to side. The sway of the body was advised and she did this a hundred times in the morning and a hundred times at night before retiring.

She told me how much better she slept at night since having had her first treatment. She said it had been many years since she had had a restful night's sleep. She enjoys walking fast on the street now, noticing stationary objects moving in the opposite direction as she walks. She reads numbers in the telephone book and other print that was not clear before. Since she has been cured, she is helping others and writes about her eyes continuing to be a blessing to her. This patient has proved again that faithful practice and patience brings about the much desired result,—normal vision.

She describes her own case in the following way: "Before I was treated by Ms. Lierman for the improvement of my sight, an American flag a short distance away looked to me like a dark piece of cloth hanging from a pole. Now I can clearly distinguish the colors; the red, the white, the blue, and I believe I could count each star if the flag would stay still long enough."

"For many years the first thing I would do on awakening in the morning would be to look for my eyeglasses. I could not see or find anything without them. At the dinner table, I could not see a small fishbone on my plate, in a poorly lighted room, much less other things that the normal eye sees without any effort. Now I can see the tiny crumbs, even though they may be as white as the color of my table cloth."

Along the street, whether I was walking or riding, I could not read signs as the normal eye does. After my second treatment all signs along the street and shop windows were easily seen by me. Before I started treatment, I could not see any objects moving at all. They all seemed to stand still. Now I can see all objects moving, that are moving, and since I have learned how relaxing the sway of the body is, I can imagine stationary objects are moving as I sway. **If I carried an umbrella or a purse on my arm, I would hold so tightly to these things that the effort caused pain in my hands and arms before I realized it. Now my**

Face the eyechart. Stand with the feet one foot apart, sway the body left and right, blink and flash the letters, one at a time See picture: Swaying right and flashing the letter B 'fraction of a second'.

Sunlight shining over the shoulder onto the microscopic fine print card. Shift quickly on the white spaces of the fine print, then the white spaces of the larger print, then fine print again... When the eyes are relaxed, vision clear, look at, read the print.

Sunlight and Sunning daily. +Face the sun, eyes closed. Move the head side to side. +Do the Sway, Long Swing, Figure Eight facing the sun. +Shift on the sun, eyes closed, left and right, top and bottom. +Practice Scaddic Sunning; move the open fingers of the hands up and down, left and right in front of the closed eyes and see moving light, color, shadows. This is a eye, eye muscle massage, relaxation, improves eye movement. +Eyes open; look at the bright sunny sky away from the sun. Spend time outside in the sun daily.

Shift part to part, small point to small point on the flag. Blink, relax.

arms and hands feel relaxed and I carry packages, an umbrella and other things without causing strain or effort. Things now come easily to me. Perhaps others who are troubled in this way would be glad to know how I was cured of this particular strain and tension caused by holding on tightly to things unnecessarily.

"Mrs. Lierman taught me how to place the palm of one hand gently, easily on the palm of the other hand. At first I did not do it gently enough for her and we practiced it together. My strain was so great, which she realized too, that I was willing to follow her in any suggestion that she made for my comfort and relief from strain. This helped me so much that I began to **uncross my knees for more relaxation and rest**. This helps more than one realizes and now since I know it does, I notice that nine out of ten people are under a tension most of the time because their knees are crossed. For years I have been under constant strain and tension, which caused greater depression than anything else. Since I have taken the treatment and followed Ms. Lierman's suggestions for home treatment, I no longer feel depressed.

"After my second treatment, I could thread a needle and I was not particular either as to the size of the eye of the needle. I believe this is worth reporting because for many years I had to have my glasses handy to thread a needle whether the eye was large or small; it made no difference.

"Since I was treated, a friend of mine drew my attention to something away off in the sky. She pointed to this object and said, 'look at that balloon in the distance!' I looked and said, 'No, it is a kite, I can see the tail clearly.' The kite became visible to my friend and she remarked how much better my eyes were since I had discarded glasses. I have much cause to be grateful for my renewed vision!"

## Perfect Sight Without Glasses

By W. H. BATES, M.D.

The author of this book presents evidence that all errors of refraction are caused by strain—and cured by rest and relaxation.

The complete method of treatment is described so clearly that the reader can usually discard his glasses and improve his vision.

For sale at this office and at trading bookstores.  
Price \$3.00 Postpaid.

### METHODS OF TREATMENT

described in  
Stories from the Clinic  
By EMILY C. LIERMAN

This book fully explains the author's experiences in treating clinic patients and her application of Dr. Bates' method of treatment to each individual case.

"Stories from the Clinic" is a contribution to the practice of Ophthalmology.  
Price \$2.00 postpaid

Central Fixation Publishing Company  
363 Madison Avenue, New York City

## Questions And Answers

Q - Is memory and imagination the same? When we remember an object, do we have to visualize it?

A - The memory and imagination are not the same. It is best when you remember an object to visualize it with the help of the imagination, but it is not always necessary to visualize it. (The brain will automatically produce a mental picture of the object.)

Q - When I try to imagine a black period, it blurs and I get all colors but black.

A - When you fail to imagine a black period, it means that you are making an effort to see black. It may help you to think of a black football that has been thrown into the ocean and is being carried further and further from shore. As it recedes in the distance, it becomes smaller and smaller until it seems only a small black speck or period.

Q - Why is it a rest to read fine print? I should think it would be a strain.

A - Fine print can be read perfectly only when the eyes are relaxed. If any effort is made, the print immediately blurs. It is, therefore, evident that the more fine print you are able to read, the more continuously relaxed your eyes and mind are.

(Fine print activates perfect central fixation, and improves close and distant vision.)

See oppositional movement chapter 17 in the book: Do It Yourself - Natural Eyesight Improvement - Original and Modern Bates Method.

Imagine a black football floating far out into the ocean until it looks like a small black period. Shift on the black period and see it swing, move opposite the movement of the eyes. Practice with the eyes open and closed.

Q - I am following your method for squint. While riding in an automobile or train, is it necessary for me to palm?

A - No. It is beneficial to observe the universal swing, that is, looking in the distance and noticing that everything on the horizon, the clouds, treetops, etc., seem to move in the same direction in which you are moving. Without looking directly at near objects, you are conscious of the fact that they seem to be moving past in the opposite direction. Remember to blink frequently, as the normal eye does.

## Perfect Sight

If you learn the fundamental principles of perfect sight and will consciously keep them in mind your defective vision will disappear. The following discoveries were made by W. H. Bates, M. D., and his method is based on them. With it he has cured so-called incurable cases:

**I. Many blind people are curable.**

**II. All errors of refraction are functional, therefore curable.**

**III. All defective vision is due to strain in some form.**

You can demonstrate to your own satisfaction that strain lowers the vision. When you stare, you strain. Look fixedly at one object for five seconds or longer. What happens? The object blurs and finally disappears. Also, your eyes are made uncomfortable by this experiment. When you rest your eyes for a few moments the vision is improved and the discomfort relieved.

**IV. Strain is relieved by relaxation.**

To use your eyes correctly all day long, it is necessary that you:

1. Blink frequently. Staring is a strain and always lowers the vision.

2. Shift your glance constantly from one point to another, seeing the part regarded best and other parts not so clearly.

That is, when you look at a chair, do not try to see the whole object at once; look first at the back of it, seeing that part best and other parts worse. Remember to blink as you quickly shift your glance from the back to the seat and legs, seeing each part best, in turn. This is central fixation.

3. Your head and eyes are moving all day long. Imagine that stationary objects are moving in the direction opposite to the movement of your head and eyes. When you walk about the room or on the street, notice that the floor or pavement seems to come toward you, while objects on either side appear to move in the direction opposite to the movement of your body. (Oppositional Movement)

## Announcement

The new edition of "Perfect Sight Without Glasses," by W. H. Bates is now on sale at this address and all leading book stores. Those who were unable to procure the book while our stock was exhausted will receive prompt delivery. Bound in green leather and embossed in gold. \$3.00 prepaid.

We wish to call to the attention of our readers, the Bound Volume of the "Better Eyesight Magazine" from July, 1926, to June, 1927. This contains articles written by W. H. Bates, M.D., on his discoveries, relative to the cure of Imperfect Sight by Treatment Without Glasses.

Each month, he discusses in detail the causes and treatment of various phases of imperfect sight. Instructions and suggestions for home treatment are also given.

Another article, demonstrating the various truths of Dr. Bates' discoveries, proves most beneficial in this treatment.

There is also a Question and Answer column in which questions submitted by subscribers and interested readers are answered by Dr. Bates.

We have only one hundred copies and advise all those who wish to keep the book as reference to send in an early order.

Bound in green leather and embossed in gold.

\$3.00 prepaid.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

OCTOBER, 1927

### Demonstrate

#### 1. That the drifting swing improves the sight.

Take a record of your best vision of the Snellen test card with both eyes together and each eye separately without glasses. Now close your eyes and imagine that you are occupying a canoe which is floating down some creek, river or stream. Imagine that the trees, houses and other stationary objects on either side are moving in the direction opposite to the way in which you are moving.

Another way in which to practice the drifting swing is as follows: With the eyes closed, recall a number of familiar objects which can be remembered easily. Sometimes in the course of a few minutes, fifty or one hundred objects may be remembered quickly and then forgotten. Remember each mental picture by central fixation; that is, think of only one part at a time of the object that you are remembering. (Shift from part to part, while seeing, thinking of each part, one part at a time.) Just let your mind drift easily from one object to another, without making any effort. Do not try to hold each object as remembered; forget it quickly. Notice that after practicing the above methods for a few minutes the vision for the test card is improved.

#### 2. That the long swing improves the sight, relieves pain, fatigue and many other nervous symptoms.

Take a record of your best vision of the Snellen test card with both eyes together and each eye separately without glasses.

+Stand, with the feet about one foot apart, facing a blank wall.

+Turn the body to the left, at the same time raising the heel of the right foot.

Now place the heel of the right foot on the floor in its usual position;

+Then turn the body to the right, lifting the heel of the left foot.

+The head and eyes move with the body; do not make any effort to see more distinctly stationary objects which are apparently moving. Practice this fifty to one hundred times, easily, without making any effort. Notice that after practicing, the vision for the test card improves.

Drifting Swing

Palm, eyes closed and imagine floating down a river in a boat. See Oppositional Movement; the trees, houses, shoreline, mountains... on the left and right sides of the river move by in the opposite direction the boat is moving to. Imagine sitting facing forward, then backward in the boat and see the shoreline, river move toward and past you and away and past you.

Shift on objects. Imagine objects clear, in color, motion. Hear, feel objects: wind blowing leaves on the ground, in the trees, river water, warmth of the sun...

The Long Swing

## Squint

### Treatments for crossed, wandering eyes

By W. H. Bates, M.D.

**DEFINITION.** When one or both eyes are habitually turned in toward the nose, the condition is called internal squint or convergent strabismus. When the eyes turn out, it is called divergent squint. Sometimes one eye may be turned up, while the other remains straight or may be turned down. This has been termed vertical squint. Some cases of squint may be a combination of several kinds of squint, vertical convergent or vertical divergent.

**CAUSE.** The cause of squint is a mental strain. Internal squint is produced by a different strain from the one which turns the eyes out, upward or downward. Double vision is produced by a mental strain different from that which lowers the vision or causes fatigue, pain or dizziness. Normal eyes have been taught to consciously produce all kinds of squint at will. This requires an effort which is variable in its intensity.

The facts suggest that since squint in all its manifestations can be produced at will, it should be considered curable by eye education, and this has been demonstrated in all cases. It is a well known fact that many persons, including children, can learn how to produce squint and become able to relieve permanently all the varied symptoms of squint. The success of the operative treatment of squint is very uncertain.

**TREATMENT.** Since squint is always caused by an effort or a strain to see, mental relaxation is a fundamental part of the successful treatment. This may explain why teaching the eyes to see better is a relaxation method, which promotes the cure of the squint. If the vision of each eye is about one-half of the normal, the right or the left eye may turn in. With an improvement in the vision of each eye to the normal, the eyes may become straight.

#### Internal Squint

Double image of light

One light is seen, eyes are straight.

Double images merged into one light, using the imagination with the eyes open and closed and by crossing and uncrossing the eyes. Read Dr. Bates full treatment to cure internal convergent and external divergent squint.

If the good eye has a vision of 15/20 while that of the poorer eye is only 15/70, improving the vision of the good eye may also improve the vision of the eye that turns in and the eyes may become straighter.

In many cases of squint, double vision can be demonstrated. These cases are more readily cured than those cases of squint which do not see double. **This fact suggests that all cases of squint should be taught how to produce double vision.** When the patient regards a small light with both eyes open, it is possible to encourage him to see two lights with the aid of prisms, (prisms are not necessary) the blue glass over the eye with good sight, when the light seen by the good eye is very much blurred. If the person is unable to imagine two lights a short or long distance apart, palming frequently helps. By resting the eyes with the aid of palming, the separation of the two lights is changed. With the help of the swinging, central fixation, the two images approach each other and may merge into one light.

Squint cases are materially benefited when they become able, by an effort, to imagine the double vision better with their eyes closed than with their eyes open. They are able to demonstrate with their eyes closed that the image seen by the right eye is to the right of the image seen by the left eye. This is called **homonymous diplopia**. By a little training or encouragement, they become able to imagine the two images closer together by relaxation methods.

When the image seen by the right eye is to the left of the other image, it is called **crossed diplopia** and, with few exceptions, divergent squint is present. With the eyes closed, a person with internal squint may imagine double vision with the images separated or close together. Or he may become able to imagine the images crossed, or the image seen with the right eye to be to the left of the other image; in other words, he may be able to produce divergent squint with the aid of his imagination. **A number of people have been cured of internal squint by teaching them how to produce divergent squint.**

Young children, two years of age, have been cured of all forms of squint by swinging the whole body in a circular direction and swinging them strongly enough to lift their feet from the floor. While swinging, the hands of the child are held by the hands of an adult who may be swinging them. At the same time the child is encouraged to look upward as much as possible. The little patients always seem to enjoy this form of exercise. Games of all kinds have been practiced with much benefit to the squint in children.

One can obtain small toy animals of various sizes and colors. The names of the animals and their colors can be taught to the children. In the beginning they learn the names of the animals more readily when they are close, about two feet away. When the child recognizes each animal correctly at this distance, one can, by gradually placing each animal further off, improve the vision for a greater distance. The more perfectly the child becomes able to see the animals, the less is the squint.

Teaching children with squint the names of the different colors at a near or greater distance is a benefit. In the beginning, the size of the colors may need to be large to help the memory, imagination or sight. As the sight improves, the child becomes able to distinguish the colors of very small objects. One may need to spend half an hour or longer daily for some weeks in order to improve the vision for colors to the maximum. Numbers and letters of the alphabet can also be taught to the child who has squint, with benefit.

#### Convergent and Divergent Squint Cure.

+Imagining double image of the light with the eyes open, then closed, then open. (As is seen if eyes were crossed.)

+Imagining images moving closer together.

+Imagining the left eye sees its image on the left side, right eye sees its image on the right side. (correct)

+Then, imagining the left eye sees its image on the right side and right eye sees its image on the left.

Swing the child in a circle counter-clockwise, clockwise... Feet leave the ground, child looks up. Straightens eyes.

#### Sway side to side.

Body, head, eyes move together, in synchronization, at the same time, in the same direction.

Sway relaxes the mind, body, eyes, prevents effort to see, strain, blur and squint.

## Double Vision

Not all children are conscious of seeing stationary objects multiplied. When they reach the age of six years or older, double vision, when it occurs, is usually very annoying. Adults with double vision and squint are usually more seriously disturbed than are young children.

One of the best remedies for double vision is palming for longer or shorter periods of time. It is well to remember that while double vision often requires the vision of each eye, one may have multiple images referred to each eye alone.

**Any method of treatment which secures relaxation, corrects the double vision and lessens the squint.** Some patients are benefited by standing with the feet about one foot apart, the arms and hands hanging loosely at the sides, while they **sway** the body slowly, continuously, easily, from side to side. The swaying of the body from side to side lessens or prevents concentration or other efforts to see. Since double vision can be demonstrated to be caused by concentration or some other effort to see, the prevention of effort by the sway naturally lessens or corrects double vision. Should this not be sufficient to cure the squint, one may practice **blinking, palming, or the memory or the imagination of perfect sight.**

**The Snellen test card** may be useful in the cure of squint. While swaying from side to side, standing a few feet from the card, all stationary objects in the field of vision may appear to be moving in the opposite direction to the sway. More distant objects, that have no background, may appear to move in the same direction as the movement of the body. When practicing with a white card with black letters, the whiteness of the card improves in whiteness, while the blackness of the letters becomes darker and the vision improves.

## The Tropometer

The tropometer is an instrument invented by Dr. George T. Stevens, of New York, to measure the strength of the muscles of the outside of the eyeball. It is a very valuable instrument for some cases. For example, a patient, a young man of about twenty-three years of age, came to me suffering from an alternate squint of a very high degree. I measured the strength of the muscles which turned the eyeball in. He had the maximum strength of these muscles. A free incision was made through both muscles and the result was negative. The eyes turned in as much as they had before the operation.

In order to increase the effect of the operation, I removed a quarter of an inch of the internal rectus muscle and then measured the effect produced with the aid of the tropometer. Much to my surprise, the tropometer measured little or no diminution of the strength of the internal rectus to turn the eyeballs in. I then proceeded more or less cautiously, alternately using the tropometer to

measure what progress I was making.

When the tropometer indicated that the strength of the internal rectus was reduced to normal, functional tests demonstrated that both eyes were straight, with single vision. I exhibited the patient before the Ophthalmological Section of the New York Academy of Medicine. Every ophthalmologist, and there were many prominent men present, made the statement that the eyes would turn out within a very short time. Twenty years later, a large, heavy man came up to me after I had finished a lecture on the cure of the eyes at one of the public schools of New York. Although I did not recognize him, he was the same patient. He had had no relapse during all these years.

Dr. Bates main treatment is to avoid cutting the eye muscles. Natural Bates method doctors have learned to use relaxation, shifting, central fixation, movement, left and right brain hemisphere activation, integration, (professional alignment of the neck vertebrae and skull/eye socket bones only if necessary) and other natural treatments to cure cross and wandering eyes.

## Case Reports

About fifteen years ago, a southern lady came to me with her daughter, age ten. When she arrived at the office, she found a number of patients who had come to be cured of their bad eyesight without glasses. She was one of those nervous people who disliked above all things in this world to have to wait, especially in a doctor's office. When my secretary advised her not to wait, she took a firmer grip on the arms of her chair and resolved to see it through.

The child was suffering from well marked alternate internal squint. Sometimes the right eye would turn in so far that the pupil was covered over by the inner corner of the lids. At other times, the child was observed to be afflicted with internal squint of the left eye. Her mother told me that they had been to several large cities, including the capitals of Europe, where she had hoped to obtain a cure for her daughter's squint.

The child was an avid reader and had read many books. Her memory was unusually good. She also had a very good imagination. She could read the 10 line of the Snellen test card at more than twenty feet in a good light. When the light was poor and her vision was tested with the aid of a strange card, she was able to imagine correctly each of the four sides of any letter. For example, the letter "E" was the fourth letter on the fifth line of the test card. When the test card was placed thirty feet away in a poor light, she was unable to distinguish the letter as a whole.

After closing her eyes and covering them with the palms of both hands (palming), she imagined the left side of the "E" to be straight. When she imagined the left side of the "E" was curved or open, she strained. She imagined the top straight, and the bottom straight, and the right side open, which was, of course, correct. When any of the sides were imagined wrong, she always strained and was more or less uncomfortable.

She was then asked to imagine the fourth letter on the sixth line. She was still practicing palming. She was able to imagine the left side of the unknown letter to be straight, the top straight, the bottom open and the right side open. She imagined that the letter was an "F" and was correct.

She was then tested with diamond type at about ten feet from her eyes, a distance at which it was impossible for her to read the letters. She was then told to palm. While palming, she was asked to imagine the first letter of the fourth word, on the fifteenth line of the diamond type. With her eyes closed and covered, she was able, without effort, by imagining each of the four sides correctly to demonstrate a letter "M." She imagined this letter so perfectly that she was able also to imagine other letters of the same word correctly. The exercise of her imagination was continued for an hour during which time she imagined correctly a number of lines of the diamond type. The result was very gratifying, because the squint disappeared in both eyes and the relief was manifest two days later.

Imagine and see one letter clear and all letters, objects become clear.

The mother supervised the imagination of the fine print for half an hour daily for many days and weeks, with the result that at the end of six months, the child's eyes were still straight. The treatment was then discontinued, and at the end of five years, her eyes still remained straight.

A girl, age twenty-five, was afflicted with a **complicated squint of various muscles of the eyeball of each eye**. She habitually looked straight with the right eye, while the left eye turned down and out. When the right eye was covered, the left eye looked straight, and the right eye turned down and out. She had a vertical divergent squint in each eye. At times, she turned the left eye up and inward.

**She was instructed to produce all forms of vertical, internal or external squint.**

With her eyes closed, she was directed to place her fingers lightly on the outside of the closed eyelids. With the help of her imagination, she became able to move the right eye in, while the left eye remained straight. When the left eye turned in, the right eye remained straight. She could produce every imaginable form of squint with her eyes closed, better than she could produce a squint with her eyes open. With her eyes open, she was able to do it in flashes or temporarily and later more continuously. It was interesting to observe how readily the patient could tell by the sense of touch whether the eye was looking in, out, down, up, or straight.

Practice this with the eyes open, closed, open: Remember, imagine parts of a letter correct. Remember, imagine the top of the E straight (correct) and relaxation, clear vision occur. Remember, imagine it curved (incorrect) and strain, blur occur.

Shift on and see, imagine correct, one part of the letter at a time. Shift part to part seeing each part, one at a time clear.

Next: practice on a small fine print letter.

### Strabismus Cure

Look at a candle flame.

+See and imagine seeing two candle flames (as is seen when the eyes are crossed).

+Cover one eye at a time to see where each eye image of the flame is seen in the left and right sides of the visual field. Then: both eyes uncovered:

+Imagine and see with an effort the two flames move farther apart.

+Then, with relaxation, no effort imagine and see the flames move close together and merge into one flame. Eyes are straight, vision clear.

Read Dr. Bates complete directions on the left.

230 *Squint and Amblyopia: Their Cure*

Fig. 54. Case of Divergent Vertical Squint Cured by Eye Education.

No. 1.—The right eye turns out and up, the left being straight.  
No. 2.—The patient learns to look down and out with the left eye while the right looks straight.  
No. 3.—The patient learns to turn both eyes in by looking at a pencil held over the bridge of the nose.  
No. 4.—The patient is permanently cured.  
All four pictures were taken within fifteen minutes of each other, the patient having learned to reproduce the conditions represented at will.

(Squint/Strabismus)

Many patients have been cured of internal squint by teaching them how to produce divergent squint, either with the eyes open or with the eyes closed. There were times when it was difficult for the patient to produce some forms of squint. With the aid of a small candle light, with the eyes open, the patient could imagine she saw two candle flames. The one seen by the right eye was to the right of the one seen by the left eye when one or both eyes turned in. By practice, she became able, with an effort, to increase the distance between the two candle flames. By lessening the effort, she became able to bring the two candle flames closer together, which was evidence that the squint required an effort and that a cure could be expected when the eyes were relaxed.

There were times when her ability to produce internal squint with her eyes open was not always easy. With her eyes closed, her imagination of the two candle flames was better. With an effort, she was able to imagine the candle flame seen by the right eye to be to the left of the candle flame seen by the left eye. In other words, the two candle flames were crossed. With her eyes closed, she could imagine the crossed images farther apart, or she could bring them closer together by relaxation until they merged into one. **Her ability to produce all kinds of squint helped her to do those things which were necessary to correct the squint. She devoted many hours to the production of vertical squint which enabled her to quickly correct divergent squint. When she became able to produce internal squint, it was not long before she was able to correct external squint.**

When the patient began treatment, she was wearing glasses for the correction of imperfect sight. After her eyes became straight by eye education, her vision became normal without glasses. Because of her wonderful control of her eye muscles, very satisfactory photographs were obtained of her eyes.

Shifting, central fixation, relaxation, no effort to see clear, no effort, strain to keep the eye straight corrects Strabismus, Squint.

## STORIES FROM THE CLINIC

By Emily C. Lierman

A young mother, who was much worried about the condition of her little boy's eyes, brought him to me for my candid opinion as to the cure of squint. When he was two years old, it was noticed that his left eye frequently turned in. At the age of three, when I first saw him, the right eye seemed to turn in more than the left. The mother had visited many eye specialists but none of them gave the child permanent relief.

I felt so sorry for the little fellow when he stood before me with his large rimmed spectacles. He tried to keep his head still while he looked up at me, but he could not. His head moved in a sort of semi-circle as he tried to see me more clearly, through his glasses. I pretended not to understand what he said to me, and he really had a great deal to say.

I sat down and took him on my lap. Then I asked him to remove his glasses so that I could understand him better. "Glasses don't talk, do they?" he said. "No; but they make me stare like you do, and I also think they make me a little hard of hearing," I remarked, jokingly. He looked at his mother and quietly asked her to remove his glasses so that Ms. Lierman could hear him better.

I had no desire to have him take me seriously, nor did I want him to feel that he was going to be examined as he had been heretofore. I asked him his name. "Frank," he said, and then gave his full name and address and the date of his birthday, which I thought was bright for a child so young. He had spent many hours and days during the last year being examined and having drops put in his eyes. He asked me if I were going to put those drops in his eyes and said that if I were, he would run away.

I told him that I would not even touch his eyes with my hands. His mother and father were with him, and to prove to Frank that I really meant what I said, I asked both the mother and father to hold my hands, which they did. In the meantime, Frank slid off my lap, threw himself on the floor before me, kicked his heels in the air and wept with fear. His father apologized for his behavior, but I assured him that it was not necessary to make excuses for little Frank, because it was not unusual for children with squint to act that way.

"Yes," the father answered, "I noticed that you emphasize that in your book, 'Stories from the clinic.'" Nothing could be done until the father threatened to take the boy from his position on the floor, and even then he kicked and screamed, begging at the same time to be left alone, saying that he wanted no drops and no examination of his eyes. I asked both parents to leave him entirely to me.

His mother took two packages of chewing gum from her handbag. One package she handed to me, while the other she held concealed in her hand. I never saw a child move as quickly as he did from the floor for that chewing gum. I said he could not have any of it until he stood on a chair, ten feet from a test card that I had placed on the wall opposite. This test card is the one we call

the inverted "E" or the "pot hook" card, and is used for young children and patients who cannot read or write.

He willingly consented to do as I wished him to, and without further fuss, he stood on the seat of the chair opposite the card.

At my suggestion, his mother stood twenty feet away from him and held a piece of wrapped gum in her hand for him to see. She

Pathologic, Yonkers, Inverted E Test Card

asked him what the name of the gum was. The mother had previously told me that he could mention the name on the wrapper of the gum and could tell whether it was Beechnut or Wrigley. He said immediately that it was "Beechnut." I watched his eyes as he looked at the gum and both were straight. I then told Frank to close his eyes and showed him how to palm. While his eyes were closed and covered, his mother replaced the Beechnut gum with the Wrigley.

Frank was then told to remove his hands from his eyes and look at the package his mother held up for him to see. He said, "Oh, I know that is Wrigley Spearmint gum." The mother then placed both hands behind her back and changed the gum from one hand to the other, then held up both hands for him to name the gum. He mentioned them correctly, saying that the right hand held the Wrigley and the left hand held the Beechnut. I drew his father's attention to the fact that when he shifted from her right hand to her left hand, noticing first the object which she held in one hand and then the object she held in the other hand, he blinked his eyes, and while swinging and blinking, his eyes moved in unison. The father remarked how straight both eyes were during this exercise.

After his mother had promised that he could soon have the chewing gum, I told the little fellow to palm his eyes again. When he removed his hands from his eyes, his right eye turned in decidedly. I pointed at a letter "E" on the test card for him to see, and he leaned forward, straining hard to see how the letter "E" was pointing. He rubbed both eyes with his chubby hands and complained that he could not see anything.

I explained to his parents how **unfamiliar objects seen at the distance caused the blindness of squint, while familiar objects seen at the same distance produced no tension, no strain, and therefore no blindness from squint.** The inverted "E" card was unfamiliar to him and made him strain.

His mother noticed, among other test cards, one that was familiar to him, but the letters of the card had not been memorized by the child. I placed this familiar test card fifteen feet away and pointed to the ten line of letters, or the line of letters that should be seen by the normal eye at ten feet, and he immediately strained to see them. His right eye turned in as it had before. I then placed the familiar test card ten feet away and directed Frank to close his eyes after he had seen each letter as I pointed to it. In this way, he read the ten line letters with both eyes straight.

I placed a toy on the floor and told Frank to go and pick it up. He reached for the toy but missed it by a foot. By turning his head around in a sort of semi-circle, he finally put his hand on the toy and picked it up. I spent almost a half-hour longer with him than I usually do with each patient, swinging him around as I held both his arms, and raising him slightly from the floor. He laughed with glee, enjoying every moment of the swing.

He was rather heavy for me to lift, so I asked his father to take my place. Frank thought this was a wonderful game and all the while his father swung him around from left to right, he looked up toward the ceiling and then to his father's face. All three of us noticed how straight both eyes were during this procedure. His parents were directed to practice this swing every day, always making a game of anything that was done for Frank's eyes. They were told to report to me, from time to time, how he was getting along.

Later, when I saw him again, I placed him fifteen feet from the test card. He knew the alphabet, as well as the numerals, so I used the card with unfamiliar letters. He covered his left eye and read with the right and when I pointed to a "C," he said, "That is a broken 'O.'" I began to smile, which disturbed him somewhat, and then asked him why he called it a broken "O."

"Why," he said, "anybody would know it wasn't broken if it didn't have an opening to the right side, and maybe grownups like to call it a 'C,' but I know it is a broken 'O' ". I pointed to a 'G' and asked what it was, he said, "That is also a broken 'O,' only it's different." He read 15/10 with each eye separately, and with both eyes straight.

I had him stand by my window and asked him to look off in the distance and notice the letter signs on the tops of the buildings. In trying to see the letters correctly, he strained and both eyes turned in slightly, the right one more than the left. He demonstrated again that unfamiliar objects seen at the distance cause more strain. Every time Frank's eyes turned in as he tried to see, he would say that he could not see at all. When questioned about whether he saw black before his eyes, he answered, "No, but I just can't see." Immediately after a failure to see at the distance, and while looking at unfamiliar objects, he would have a sort of nervous spasm, which his mother said was hysterics.

It has been some time since I have seen Frank, but I believe, or hope, that his mother has continued to help the little fellow. I always think of him when I look at the "C" of the test card, which he called the "O."

## Announcement

Dr. Bates wishes to announce that Mrs. E. C. Lierman, his assistant for fifteen years, has finished her work in California, and has resumed her work at his office.

## Questions And Answers

Q - When doing the swing, what does one move, the head or eyes?

A - One moves the eyes in the same direction as the head is moved.

Q - Does massaging benefit the eyes?

A - No, because it does not relieve the mental strain which caused the eye trouble.

Q - Is practicing under a strong electric light as beneficial as practicing in the sun?

A - If the sun is not shining, the strong electric light can be used with benefit, although more benefit is derived from direct sun treatment.

Q - Memory - Can one remember perfectly and see imperfectly?

A - It is impossible to remember perfectly and see imperfectly at the same time. Perfect sight can only be obtained with the aid of a perfect memory. When the memory is perfect, the mind is relaxed and the vision is normal. Imperfect memory requires a strain of the eyes which produces the imperfect vision.

Q - Can one blink too quickly and too often?

A - The normal eye blinks quickly, easily and frequently.

Q - What causes a white matter to appear in the eyes after sun treatment?

A - The white matter in the corner of the eye is produced by infection and is cured by sun treatment.

Q - If bad eyesight is caused by some physical ailment, will your methods help?

A - Yes, relaxation is always a benefit, not only to the eyes, but to all the nerves of the body.

NOVEMBER, 1927

### Voluntary Production Of Eye Tension A Safeguard Against Glaucoma

It is a good thing to know how to increase the tension of the eyeball voluntarily, as this enables one to avoid not only the strain that produces glaucoma, but other kinds of strain also. To do this proceed as follows:

**Put the fingers on the upper part of the eyeball while looking downward, and note its softness.**

(Place the fingers on top of the upper skin of the closed eyelids, not the eye itself.)

**Then do any one of the following things:**

- + Try to see a letter, or other object, imperfectly, or (with the eyes either closed or open) to imagine it imperfectly.
- + Try to see a letter, or a number of letters, all alike at one time, or to imagine them in this way.
- + Try to imagine that a letter, or mental picture of a letter is stationary.
- + Try to see a letter, or other object, double, or to imagine it double.

**When successful, the eyeball will become harder in proportion to the degree of the strain, but, as it is very difficult to see, imagine, or remember, things imperfectly, all may not be able at first to demonstrate the facts.**

*[The above article, which appeared in the December, 1920, issue of "Better Eyesight," is reprinted at the request of the editor, in connection with the other articles in this month's issue on "tension".]*

## Tension

By W. H. Bates, M.D.

The tension of the muscles and nerves of the human eye is a very important subject for various reasons. Perhaps the most important of all is the fact that it occurs so frequently and so universally. When a person has near-sightedness, eye tension can always be demonstrated, because when the eye tension is relieved and corrected, the near-sightedness is cured. All persons who have astigmatism have eye tension. When the eye tension is relieved, the astigmatism disappears. Patients with cataract, diseases of the optic nerve or diseases of the retina are suffering from tension. When the tension is relieved, the eye disease disappears.

In some cases, it is more difficult to relieve the tension than in others. No matter whether it is difficult or not, there can be no cure of the eye disease unless the tension is corrected. This tension, besides affecting the eyeball, is also manifest or can be demonstrated in any or in all parts of the body. **A person who has glaucoma is under, not only tension of the eyes, but a tension or an unusual contraction of the muscles of the arm, the hand, or all the muscles.**

Tension of the internal muscles is always present when a patient has a disease of the chest, and it can be demonstrated that he is also suffering from tension, not only of the chest, but also of other muscles and nerves in other parts of the body. There is a tension that contracts the bronchial tubes which interferes with the proper circulation of air into the lungs and out of the lungs. People with pneumonia, tuberculosis of the lungs, or tuberculosis of any part of the body are all suffering from eye tension, and when the eye tension is relieved, the tension in other parts of the body is also relieved. It is an interesting fact that all diseases of the eyes and all diseases of the body are generally associated with eye tension.

#### Opera Singers Voice Cured by Relaxation

A very remarkable case of tension was that of an opera singer who suddenly lost her ability to sing. Specialists on the throat examined her very carefully and they were united in the statement that she had paralysis of the muscles on the left side of her larynx. In connection with this paralysis there was a tumor grown on the left vocal cord. Her symptoms of paralysis were caused by tension, because when the tension was relieved, the paralysis of the vocal cord was also relieved and cured. The tumor which had grown on the left vocal cord disappeared.

There are two things about this case which can be discussed; one is that the paralysis was caused by tension and the other that the tumor of the vocal cord was also caused by tension. When we analyze her case and try to give an explanation of what the tension accomplished, we will probably say a good many things which are not so. It is exceedingly difficult, as I have said a great many times, to answer the question, "Why?"

We may have cases of eye diseases in which it is difficult to relieve the tension, but it may be **easy to relieve the tension in the muscles of the stomach or in the various groups of muscles in the arm, or hand, neck and when such tension is relieved, that of the eye muscles is relieved, and in this way, the disease of the eye, no matter what it may, be can always be relieved or cured. This is a very important fact, because when understood and practiced, some very severe forms of diseases of the eyes can thus be cured, and in no other way so well.**

Chronic neck muscle tension, limited movement (often caused by computer use, eyeglasses) cause eye muscle tension, impaired movement, blood flow to head, eyes, unclear vision, impaired eye health.

Relax the muscles in the body, chest, arms, shoulders, neck = the eye muscles relax, eye moves freely, eye returns to normal shape, no tension in the eye, circulation improves, eyes are healthy, vision is clear.

The question that comes up more prominently than any other is: What can the patient do to bring about relaxation of any group of muscles? A man, by the name of **F.M. Alexander, of London, England** has accomplished a great deal in the cure of all kinds of diseases. He says that all diseases of the body are caused by tension. They can all be cured by the relaxation of the tension. He has offered many methods of bringing about relaxation in the most interesting, although seemingly incredible way and the most successful is to bring about relaxation by having the patient state that it is desired. (Alexander Method)

For example, a patient sitting in a chair or lying down on the floor, whichever is easier, says: **"I desire relaxation of the muscles of my neck, so that my head can be lifted forwards and upwards."** This is sometimes repeated one hundred to a thousand times. Mr. Alexander has always succeeded in having the patient bring about relaxation of the muscles of the neck by this method.

Mr. Alexander goes further and brings about relaxation of the muscles of the chest, both outside and inside, by having the patient say: "I wish my shoulder to relax and to move downwards and backwards. I wish my chest to relax and to move backwards. I wish my whole body to relax and move backwards. I wish my foot to move backwards without effort, without strain of any muscles of the body." Relaxation of the body, back, chest, shoulders, neck results in easy movement, relaxation of the eye muscles, eyes, and clear vision.

It has been a great shock to many orthodox physicians to observe the cures that Alexander has made. Epilepsy, considered by the medical profession to be incurable, has been cured by relaxation, without the use of any other form of treatment. Of course, rheumatism responds perhaps more quickly to relaxation than a great many other diseases, but there are cases of so-called rheumatism affecting the shoulder in which all parts of the joint become immovable.

One patient was afflicted with Parkinson's disease; all the joints of the body became so fastened together, so immovable, that the patient was unable to produce any voluntary movement of the hand or the arm. As time passed, the voluntary and the involuntary muscles gradually became useless from tension. Mr. Alexander had the patient relax those muscles which she could relax most readily. When this was done, the more difficult muscles became relaxed, until finally she was cured completely by the relaxation of tension.

(The Alexander Method and other body movement exercises) continues to be popular today, 2010; original and modern Natural Eyesight Improvement teachers apply body, neck relaxation, movement as a main eyesight improvement treatment.)

### Bier's Congestive Treatment The Coal Miner

We may say that tension is a very important factor in the cause of most diseases of the body. A very instructive case was the following: About twenty years ago I came into my clinic and found there a coal heaver whose face and hands and all parts of his body were covered with soot, or black particles of coal. His right eye was suffering from an ulcer of the front part. The case interested me very much and I took him in to see the surgeon in our department, a man who believed very strongly that an abscess in any part of the body is caused by germs, and when there is a collection of pus, it is the physician's duty to drain it and get rid of it. I said to him:

"Would you drain that pus?"

He answered: "Certainly, a man would be crazy not to drain it."

I then said: "Doctor, do you know that some patients in this condition, who have had the pus drained have lost an eye, and oftentimes both eyes from sympathetic ophthalmia?"

"I don't care, it ought to be drained," he said.

"Just watch me, I said.

Without cleansing the patient's face or eyes, a pressure bandage was placed over his eye and tied so tightly that his face became much swollen. I told him that in two days, his eye would be cured. The surgeon said:

"Impossible."

I said, "Take a good look at him so that you will recognize him if you ever see him again."

At the end of two days, the man came back, very much annoyed with me. He said that the bandage nearly killed him.

"Take it off," I said.

He took it off and the pus had disappeared. The surgeon who saw it said that I had not cured him, that the man did not have an abscess to start with, that he had a perfectly healthy eye, and that anybody who said that the eye was full of pus two days before was wrong.

Strange as it may seem, the pressure bandage relieved the tension in the eye to a considerable degree, with a result that the pus in the anterior chamber was entirely absorbed. The eye recovered its health in forty-eight hours and the eyeball became very soft, because the tension was relieved. Working in a dark coal mine, lack of sunlight impairs the health of the eyes. Mules working in the mines developed cataracts and other eye problems, blindness.

It is well to demonstrate the results produced by tension. When the letter "O," for instance, is remembered imperfectly, the white center becomes a shade of gray and the black part of the letter becomes less black and often covered with a gray cloud. To remember an imperfect letter "O" requires an effort. The effort tires the eyes and mind. The memory of imperfect sight lowers the vision of other letters. When the effort becomes sufficiently great to blur the letter "O" more completely, the tension becomes increased, the eyes feel uncomfortable and may suffer considerable pain. **This pain may be felt in the head, back of the neck, in the arms and in other parts of the body.**

The memory of perfect sight does not produce fatigue, pain or any other form of discomfort. The memory of perfect sight can only be accomplished easily. Any effort, strain or tension spoils it. Eyes, clarity of vision, memory, imagination function together, are integrated. Improve one and all improve. Practice improving every function and all are greatly improved.

When the sight is perfect, it is possible for the memory to be perfect, because we can only remember what we have seen; when the memory is perfect, the imagination is perfect, because we can only imagine what we remember. When the imagination is perfect, the sight is perfect, because we can only see perfectly what we imagine perfectly. The demonstrations of these facts have repeatedly appeared in this magazine and should have suggested methods of treatment of the greatest value.

Remember, imagine the letter O incorrect - a gray blurry center, the black ink a light black/gray color smearing onto the white page. The eyes, mind tire, strain and vision is unclear.

Remember, imagine the O clear, dark black, the white center pure white - relaxation and clear vision occur.

Many writers have stated that imperfect sight can be obtained without any difficulty. Usually, the contrary is the truth. Recently a girl was treated for nearsightedness. With some instruction, she became able to demonstrate that to see a letter "O" imperfectly for any length of time was difficult or impossible. She imagined the left hand side of the letter "O" to be straight. I asked her how it felt. She answered: "It hurts."

Then I asked her to imagine that the right-hand side was open. She quickly said: "It hurts."

Then I asked her what she meant by saying, "It hurts."

"Well," she replied, "when I imagine a part of a letter wrong, my eyes feel uncomfortable and I don't like the feeling."

I then said to her: "Can you imagine what this letter might be?"

"Yes, I can imagine what it might be, but it hurts."

Then I said, "Suppose you imagine it is an 'O,' what happens?"

She smiled and said: "That doesn't hurt. It is an 'O.'"

I then pointed to a letter which came after the "O" and asked her if she could imagine what it was. She said: "Don't ask me, because it hurts."

I then asked her to close her eyes and remember the letter "O." She was able to do this without any discomfort. The next step was to have her look at the letter "O" on the card, remember it as well as she could, with her eyes closed, and then imagine that she could see it. The memory and the imagination were repeated a number of times until she told me that the letter which came after the "O" was a "K." I said to her:

"Are you sure?"

She answered, "No."

"Why not?"

"Because it hurts."

"Can you imagine that the left hand side is straight?"

She answered: "Yes, and it doesn't hurt."

"Can you imagine the top is straight?"

"Yes," she answered, "and it doesn't hurt."

"Can you imagine the bottom is straight?"

She said, "Yes and it doesn't hurt?"

"What is the letter?" I asked her.

"The letter is 'E,'" she said, "I am sure. Yes, I am positive that it is a letter 'E' because it doesn't hurt."

During this treatment, the patient's friends and relatives became interested. She had them all practice it and all of them were able to demonstrate that when they imagined the letters or parts of the letters correctly, there was no pain, and when a letter or part of a letter was imagined incorrectly, decided pain and symptoms of tension were produced.

Remember, imagine a letter correct with the eyes open, closed, open and the mind, eyes relax, the letter is seen clear.

Shift on parts of a letter and remember, imagine the parts/letter clear, correct. Practice this with the eyes open, then in the imagination with eyes closed, then eyes open again. When the letter, its parts are remembered, imagined correct: relaxation occurs and vision is clear.

## STORIES FROM THE CLINIC

### Tension in Myopia

By Emily C. Lierman

MISS HILDRETH LENNOX, aged twenty-eight, came to me as a patient on May 2, 1927. She informed me that she had read, "Perfect Sight Without Glasses," and had studied it for about a year before coming to me. During that time she had discarded her glasses entirely after having worn them for fourteen years. Her vision was R.V. 15/200-blurred. L.V. 15/200-blurred.

When she read the card with both eyes, she could just about make out the 70-line, and the letters were more blurred than the 200-line letters. She enjoyed palming, so while she had her eyes covered, I asked her to remember anything that she could remember having seen, without effort or strain and if possible, to remember only pleasant things. She understood very readily that memory of unpleasant things caused more strain. Being a musician, she could remember her notes very well and also compositions that she enjoyed playing on the piano. She described to me, while her eyes were closed, how she had worked her way from Canada to Palo Alto, California, by giving concerts on the way. Her home is in Canada, but she is now staying with her aunt, Mrs. Tucker, in Palo Alto.

After she had palmed for a while, I taught her the universal swing. This she did gracefully. She remembered to blink each time she swayed to the right. I have noticed that the myopic patient makes a hard task of blinking. A strain is produced then, and the vision does not improve except for an instant. Then I notice that the patient squints and squeezes the eyes almost shut. To avoid this, I have them swing just a little faster than usual.

I find that the patient likes to blink in unison with the sway in one direction only, and not to the right and then to the left.

I test the sight of the patient with the white test card first—the one with the red and green lines. After the patient has palmed and has practiced the universal swing for a period of ten minutes or a little longer, I again test the sight of both eyes at fifteen feet.

I did this in Ms. Lennox's case and the vision improved to the 30-line, but all the letters of this line were seen double. The patient was again asked to palm and to describe to me what she remembered having seen from the train window on her way to the Coast. This helped her to relax so that when her test was made again—this time with the black test card with white letters—she read all of the black card at ten feet, as she covered her eyes for a part of a minute after flashing each letter. When she was told that she could not possibly stare if she covered her eyes after seeing one letter of the test card at a time, she never stopped smiling as she

Palm and remember, imagine pleasant things, objects that were seen easy, without effort, strain. Lady likes to remember her music notes, playing piano, traveling the cities, towns from Canada to Palo Alto, California. She remembers, imagined objects she saw in the past clear. This improves her vision.

Long Swing, blink and shift for a 'fraction of a second' on a letter on the eyechart when the body, head, eyes swing to one side. Don't stop, continue swinging. The sway can also be done by facing the chart and rocking left and right and flashing the letters.

read one letter and then another of the test card in this way.

I did not have another patient until more than two hours later, so I spent more time with Ms. Lennox than I usually do with any patient. She did so well for me that I encouraged her to go right on regardless of the time. Again she covered her closed eyes and explained her **mental pictures**, and when she removed her hands from her eyes and then **swayed her body, blinking as she swayed to the right, she flashed 10/10 of the black card and each letter was seen clearly.**

To the right of her, also ten feet away, I had placed a test card on the wall. I directed her to blink as she moved her body to the right, and to flash a letter of the card that she could see without making an effort of any kind. I explained that the letter could be seen best by looking a little above or below it, or a little to the left or the right of it. She said that she could see the letter more clearly when she followed my suggestion. She said that the letters almost disappeared, or became double, when she looked directly at the letter as she flashed it.

Modern teachers state to look directly at the letter;

The letter can be seen clear, looking directly at it, (central fixation) when the eyes shift on the letter, even if for only a split second as the eyes flash the letter.

The memory of each of the letters seen helped her to read the black test card more easily. After she had finished reading the last letter of the 10-line, I was amazed to have her ask this question:

"Mrs. Lierman, I have not seen this card before, so I am not sure, but I see a figure 10 over the 10-line letters very plainly. Am I right?"

I became excited myself and answered, "Why, yes, but according to most of the eye specialists, it is impossible for you to see that figure 10 at ten feet. You should see that figure only at five feet with the normal eye, not at ten feet."

Switching Back and Forth, Near and Far

I find that myopic patients improve their sight and are cured more quickly by having them **stand near a window and look off in the distance at large signs about a block away, or perhaps not quite so far.** When the patient is able to **see the large letters of the signs by blinking and shifting to a smaller sized letter of the test card, they soon become able to distinguish sign letters which they did not know were there at all when they were first asked to read the signs within their line of vision.** Ms. Lennox could only see the large letter of a sign about half a city block away from my window. The smaller letters were blurred to her and she was not encouraged to try to read them.

On May 3, her second treatment, we stood at the window before test-card practice, shifting to a large letter of a sign she had seen the day before. She became able, by blinking and shifting to the skyline, flashing a white cloud in a blue sky and then back to the sign letters, to read a sign which had letters, I should imagine, about a foot high. This sign was more than three city blocks away. The patient never stopped smiling and I was encouraged to help her more in this way.

The little blue booklet with Bible type was given to her. We used the page that has Psalm 119 on it, and which has more white spaces than either the Beatitudes or Psalm 23. Holding the fine type about six inches from her eyes, she was told not to read the type, but to look at the white spaces and remember them with the eyes closed. Alternately closing her eyes for a part of a minute and then opening them for a second, she read the small sign letters at more than three blocks away.

When she looked at the fine print, which she did often, she asked me if she could read a sentence or two. At first she read the fine print, which was easy for her to do, at a little more than four inches from her eyes. I wanted to see how far off she could hold the type and still read it. At six inches the print was not clear and the white spaces were less white-they seemed gray to her.

I told her to look at the white clouds as they moved very slowly and gracefully in the beautiful blue sky above us. She said she could easily remember the cloud being very white and the sky a beautiful blue as she alternately opened and then closed her eyes. Each time she remarked that the white clouds could be remembered whiter and the blue sky bluer while her eyes were closed. While she was practicing this, I took hold of her right hand, which held the Bible print. I drew it twelve inches from her eyes. When I told her to look at the white spaces and not worry about the type at that distance, she smiled and remarked, "Why, I can read this fine print just as well at this distance." Memory, improved by imagining white clouds and a blue sky as well with her eyes open as with them closed, improved her myopia. Then we started the test-card practice. She read a strange white test card with the black letters at 15/15 with each eye separately.

On May 4, when my patient came again, I noticed that her eyes looked tired. She said she feared that she had practiced too hard, or had made too great an effort to improve her imperfect vision. I told her she had no cause for worry and to just forget about it. We again practiced with **microscopic print, shifting to the distant building signs more than three city blocks away, then back to reading a sentence of the microscopic type** by looking at the white spaces instead of the print. (Then when the eyes are relaxed; look at, shift on, read the microscopic print.) She read smaller letters of the signs far away and her eyes were wide open. She also read another test card that she had not seen before, and at the normal distance, 15/15.

On May 5 she had all smiles and both eyes were wide open. She informed me that she had made a discovery. She said, "Do you know that I don't dare to stop blinking, because if I do, my eyes feel like hornets' nests. They sting. I can get relief only by blinking. I make it a habit now, to read smaller letters of words and signs on the housetops. I shift from the white line of my fine print booklet to distant signs that I see as I walk along the street or while riding in the trolley cars. **Shifting from the near point to the distance always improves my eye-strain and relieves any tightness that comes for an instant when I stop doing the right thing. The moment that my eyes feel uncomfortable, I find out, to my sorrow, that I have been unconsciously staring.** I have learned that by **shifting and blinking**, I see all words move the least bit when I read, and I can now read book print for hours without any discomfort.

"I notice that when I sit at my piano and read my music, I can sit perfectly straight instead of leaning forward to see my notes. I feel proud that I can see just as well without leaning forward. I now read my notes easily at the right distance. I feared becoming round-shouldered from leaning over to see the notes. I noticed, too, that when I do not see things moving, my eyelids seem to close and I feel tired quickly."

On May 6 Miss. Lennox read Number 15, which is diamond sized type, with the Fundamental truths by Dr. W. H. Bates on the

+Blink and shift on a letter on a distant sign through a open window.  
 +Then shift on a letter on the close eye chart. Repeat.  
 +Blink and shift upon (for a fraction of a second 'flash') a distant cloud, then shift on the letter on the distant sign. Repeat.  
 +Shift on the white spaces on the Fine Print Bible at 6 in. from the eyes and imagine them pure, glowing white with the eyes open, then closed for part of a minute.  
 +Then, open the eyes and read, see clear the words on the distant sign for a fraction of a second.  
 +Repeat looking to the distant sign, clouds... and then looking at the white spaces on the fine print, then, look directly at and read the fine print.

opposite side, at three feet, ten inches. I produced the small test card with the inverted "E's," and held it at a further distance from where she was standing. She began the universal swing, blinking always, and read the bottom line of the card at four feet, ten inches.

The normal eye can tell the direction in which the letters of the bottom line of the inverted "E's" are pointing, at two feet-not at four feet, ten inches-so her vision had improved to more than normal in five days. I saw the patient a week later and her vision was still the same. On her last visit she told me that she had been warned by an eye specialist in Canada never to leave off her glasses again or she would go blind.

She said, "you know how well I appreciate what you have done for me. I can now see my friends across the room better without my glasses than I could with them. Before I came to you for treatment, my friends at a tea found fault with me because I did not return their smiles when I looked at them from the other end of an ordinary-sized room. It was not so long ago that I could not read the 'Specials' on the menu card in a restaurant without my glasses. Now I can read clearly the print on my menu card that would be best for me not to read, such as French fried potatoes and other things that I enjoy, but which are not good for me."

## Case Report

The following is a report of a case treated by Miss Anne Woessner, West Nyack, N. Y. Ms. Woessner is one of Dr Bates' representatives.

Ada, aged 24, from childhood has had hypermetropia combined with partial paralysis. Very strong glasses had been prescribed for her by a New York specialist. These glasses were shaped like two miniature searchlights, which, together with the nosepiece and shafts, resembled some fantastic bug.

Last February, the first time she came to me, she had left off her glasses. It was indeed pitiful to see her walk up the short path from the gate to the porch steps. Without her glasses she could only see a dim, blurred outline of people or objects two feet away.

Upon test the four and one-half inch high "C" appeared a gray smudge at two feet. When handed a card printed with regulation reading type she saw only a blank.

After **palming** one half hour, she became able to read the 70-line at four feet. I then explained the importance of **blinking**, **shifting** and **swinging**, which she practiced for twenty minutes. This resulted in the reading of the 20-line at four feet, but blurred and gray in color.

She practiced faithfully at home the following week and started the next lesson with 4/40 quite clear. From this time on she improved steadily. The **sun treatments** became so soothing that she often dozed, much to our mutual amusement.

Her phenomenal memory greatly helped her to relax. She could relate many incidents which had happened in her childhood. Often I would read a story while she palmed and while still palming, she would repeat the story almost verbatim. This always helped. The large letters became clearer and the small type on the "Fundamental" card seem to be very clear to her in spots.

With the practice of **central fixation**, **memory of period** and **two to three hours of sunlight daily**, she is now able to read newspaper type slowly and the diamond type on the back of Dr. Bates' professional card. The change in her appearance is as remarkable as that of her sight. She is now a true sunshine girl with large eyes of blue, cheeks and hair touched by the sun, and is smiling always. She fairly flies around her home. She phoned me specially one night recently to say that she had read the clock clear across the room.

There is still much to be done, however. She has had just fourteen treatments to date and if she continues to practice so conscientiously she surely will be rewarded eventually with normal sight.

In closing I wish to state that I am still holding her glasses which she handed me upon her second visit. "Don't ever want to see them again."

Beginning of treatment, this lady had very blurry vision, had to feel her way up the path to Dr. Bates office. After treatment with Bates method, she could see and walk with ease.

## ANNOUNCEMENT

During the month of November, the following back numbers of "Better Eyesight" are selling at ten cents per copy:

July 1919 Central Fixation	Apr. 1922 Perfect Sight
Sept 1919 Flashing Cure	Without Glasses
Nov. 1919 Memory Cure	July 1926 Myopia
Dec. 1919 Shifting and Swinging	May 1927
Dec. 1921	Nov. 1920 Squint
Mar. 1920 Progressive Myopia	Oct. 1922
Dec. 1920 Glaucoma	Aug. 1920 School Nos.
June 1926	Aug. 1921
Oct. 1922	Aug. 1927
	Oct. 1920 Imperfect Sight
	Dec. 1924

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

DECEMBER, 1927

### Favorable Conditions

The vision of the human eye is modified in many ways when the conditions are unfavorable to good sight. Unfavorable conditions may prevail when the light is not agreeable to the patient. Some patients require a very bright light and others get along much better in a poor light. Many cases are hypersensitive to the light and suffer from an intolerance for light which has been called **photophobia**.

While intolerance of light may be manifest in most cases from some diseases of the eyes, there are many cases in which the eye is apparently healthy and in which the photophobia may be extreme. **(The cure for this condition is to have the patient sit in the sun with his eyes closed, allowing the sun to shine on his closed eyelids as he moves his head from side to side.)**

There are patients with good sight whose vision is materially improved when used in a bright light, as well as those with good sight whose vision improves when the eyes are used in a dim light. **The patient should practice with the test card in a bright as well as a dim light to accustom his eyes to all conditions.**

Reading in sunlight and in dim light improves the clarity of vision when relaxation is applied and effort, strain, squinting are avoided. A boy improved his vision by reading comic books at night by flashlight under the covers in his bed.

The fact that he enjoyed the comics, and that the print and pictures kept his eyes moving, shifting and improved use of his memory, imagination, all which induced relaxation resulted in clear vision.

#### Halos - The white Glow

The ability to perceive **halos**, or an increased whiteness, around letters is a favorable condition. By using a screen or a fenestrated card, it is possible for many patients to see an increased whiteness around a letter, which improves their vision for the letter. When a screen is not used, one may be able to **imagine a white halo around the inner or outer edge of the black part of the "O."** When a screen covers the black part of the letter "O," for instance, the white center becomes of the same whiteness as the rest of the white page, which proves that **it is the contrast between the black and the white which enables one to imagine the white halos. The presence of the black improves the white; the presence of the white improves the black.**

The Halo appears as a bright, pure, glowing white on the white paper around and inside black letters. The halo is brightest, whitest on the white page closest to the edge of the blank ink. Halos can also be seen around other colored letters, objects.

### Routine Treatment

By W. H. Bates, M.D.

Many doctors do not think well of treatment which has become continuously the same. I believe, however, that when routine treatment benefits a large number of patients, one is justified in practicing it in most cases. In the beginning, the writer very soon became impressed with the fact that there was something about routine treatment which had advantages over other forms of treatment. The particular advantage was speed; that is to say that by routine treatment it was often possible to cure many cases at the first visit. However, to obtain the best results, I have found it necessary to modify the routine from time to time, or to make certain changes whenever improved methods of treatment were discovered. If a patient does not respond readily to a regular routine, it is evidence that this treatment is not for him and that he requires a different form of relaxation treatment.

When a person presents himself for treatment, a record is made of his name, address, date of birth, et cetera. (If the patient is over fifty years of age, one should be prepared to treat presbyopia; all persons over fifty years of age are usually unable to read fine print at six inches without glasses.)

(Bates discovered that many people over 50 years old can see fine print clear. Presbyopia is curable, can be prevented.)

The next procedure is to have the patient remove his glasses, if he is wearing them, and test the vision of each eye with the aid of the Snellen test card at fifteen or twenty feet. If none of the letters can be seen at this distance, the card is placed at eight feet, five feet or nearer and the vision tested at that distance. The eyes are then examined with the ophthalmoscope or retinoscope.

**(The ophthalmoscope is valuable in diagnosing cataract, opacities of the cornea and diseases of the interior of the eyeball. The retinoscope is used in diagnosing near-sightedness, far-sightedness and astigmatism.)**

**REST:** The patient is then directed to either close his eyes or palm for half an hour, whichever is more comfortable for him. In **palm**ing, the patient closes both eyes and covers them with the palms of both hands, in such a way as to exclude all light. To palm successfully, he should make no effort to remember, imagine or see black. If black cannot be seen perfectly, the patient is told to let the mind drift from one pleasant thought to another.

**THE SWAY:** After the patient has rested his eyes or palmed for half an hour, he is directed to stand before the Snellen test card, with his feet about one foot apart and then to open both eyes. He is then told to sway his body gently from side to side, while his vision is again tested with the card. While swaying from side to side, he is told how to imagine the Snellen test card to be moving. His attention is called to the fact that when his body, head and eyes move to the right, the Snellen test card moves to the left, and when he moves to the left, the Snellen test card appears to move to the right. (Oppositional Movement)

The patient then is called upon to demonstrate that when his eyes move from side to side, that not only does the Snellen test card move from side to side, but that all the letters or figures on the Snellen test card move with the card. It is well to have the patient demonstrate also that when an effort is made to stop the movement of the letters, the letters become blurred or cannot be seen. The sway is beneficial in many ways because it lessens or prevents the stare, tension and strain.

**BLINKING:** It can always be demonstrated that when a patient with imperfect sight looks intently at one point, keeping the eyes open constantly, or trying to do so, a strain of the eyes and all the nerves of the body is usually felt, and the vision becomes imperfect. It is impossible to keep the eyes open continuously without blinking. Each time the eyes blink, a certain amount of rest is obtained and the vision is benefited. For this reason, the patient is instructed to **blink frequently while swaying before the card, and at all other times.**

**CENTRAL FIXATION:** Central fixation is seeing best where one is looking and worst at all other points. When the patient is swaying before the card, he is told to see one part of a letter which he is regarding at a time and to see that part better than any other part, then to quickly shift his glance to another part, seeing that part best and other parts of the letter worse. The letter is seen much more readily in this way. The patient is reminded that the normal eye uses central fixation at all times.

**IMAGINATION:** Another method is to improve the vision by a perfect imagination. If the patient is unable to see the letters on a certain line, he is told what the first letter is and is directed to close his eyes and imagine that letter as perfectly as he can, and then alternate by imagining it as perfectly as he can with his eyes open. When the letter is imagined perfectly enough, other letters on that line when regarded are seen and not imagined.

It is very evident that one cannot imagine unknown letters. Therefore, if the vision improves by the use of the imagination, unknown letters when regarded are seen and not imagined. It has been repeatedly demonstrated that an **opacity of the cornea** which may be so dense that the pupil or iris are not seen, will **clear up in some cases after the alternate imagination of a known letter or a known object is practiced with the eyes open and closed.** When opacity of the lens is examined with the aid of the ophthalmoscope, the opacity becomes increased when the patient remembers imperfect sight. The memory of imperfect sight causes a contraction of the muscles on the outside of the eyeball, which in turn produces imperfect sight, cataract, cornea scar...

**MEMORY:** The pupil is told to remember a small letter "o" with a white center which is whiter than other letters on the Snellen test card. A small letter may be imagined much better than large letters of the Snellen test card. When the facts are analyzed, it is discovered that the reason small letters are imagined better than large ones is because a small letter has not so much of an area to be seen. It is easier for the eye to remember or imagine a small object than a large one. A perfect letter "O" can only be remembered when no effort is made; an imperfect letter "O," on the contrary, is difficult to remember. When a letter "O" is remembered very black with a very white center, the vision is benefited because no effort is made.

A great many near-sighted patients believe that they can remember or imagine an imperfect letter "O" much easier than a perfect letter "O." These people are encouraged to remember or imagine an imperfect letter "O," which helps them to understand and realize as thoroughly as possible that the memory or the imagination of imperfect sight is very difficult and requires a good deal of hard work, whereas **the memory of perfect sight can only be accomplished easily without effort.**

**THE PERIOD:** With the help of the imagination, alternating with the eyes open and closed, it is possible for many patients to remember or imagine they see a small black period. It may not necessarily be a black period but may have any color of the spectrum and be of any shape—round, square, triangular or irregular. It is impossible to remember or imagine a period that is stationary. It must always be remembered by central fixation and be moving. Some patients can imagine a period as small as it is printed in the newspaper. Unfortunately, it is difficult or impossible to teach all patients how to remember a period perfectly. **The great value of the period is that when it is remembered perfectly, many serious diseases, such as opacities of the cornea, opacities of the lens, diseases of the retina and choroid, diseases of the optic nerve and blindness can all be relieved promptly.**

**SUN TREATMENT (with Memory, Imagination and Palming):** An important part of the routine treatment is the use of the direct sunlight. The patient is told to sit in the sun with his eyes closed, moving his head a short distance from side to side, and allowing the sun to shine directly on his closed eyelids. He is instructed to forget about his eyes, to think of something pleasant and let his mind drift from one pleasant thought to another. Before opening his eyes, he palms for a few minutes. When the sun is not shining, a strong electric light (1000 watts) is substituted. The patient sits about six inches from the light, or as near as he can without discomfort from the heat, allowing it to shine on his closed eyelids as in the sun treatment.

**FINE PRINT:** If the patient has presbyopia, he is directed to practice with the fine print in the Fundamental card in the following way: The card is held at first at the distance from his eyes at which he sees best. He is told not to look directly at the letters, but just at the white spaces between the lines and imagine that they are perfectly white - whiter than the margin. He is asked if he can imagine that there is a **thin, white line beneath each line of letters, and that it is whiter than the rest of the white spaces between the lines.**

Blinking rests the eyes, activates shifting-eye movement, tear production, coats the eyes, cornea with tears that clean, nourish, protect the eye/cornea, prevent dry eyes and act as a natural contact lens increasing the clarity of vision. Blinking prevents over-exposure of the eyes to strong light.

E

Shift dot to dot on the E seeing one dot clearest at a time in the center of the visual field.

The bird is seen clearly by placing it in the center of the visual field. The eyes are looking at the middle of the bird, placing it in the exact center of the visual field. (See dot=exact center.) The dot (center) moves with the eyes as the eyes shift part to part, point to point on the bird seeing one part (actually one small point) clearest at a time.

Shift on a known letter and imagine it clear with eyes open, closed, open. All letters become clear.

Remember, imagine and shift left and right, top and bottom... on a small black period. See it move in the opposite direction the eyes shift to. Practice with the eyes open and in the imagination with eyes closed.

Sun Treatment, Sunning.

Read Fine Print daily. + Look at and imagine the white spaces between sentences pure, bright white. + Then, repeat this in the imagination with the eyes closed. + Eyes open: See the Thin White Line under the sentences. Next: Look directly at the print and see, read the letters clear.

When this line is imagined perfectly white, the eyes then shift to, look directly at the letters and the letters are read without effort or strain. If the patient cannot imagine the white line easily, he is told to close his eyes and think of a series of white objects; he may recall a white-washed fence, a snow drift, several pieces of white starch, or a pot of white paint. He is then directed to open his eyes again and look at the white spaces, imagining them to be as white as the white objects he remembered. He is told to close his eyes again and imagine that he has a pot of white paint and a fine pen and that he is drawing a thin, white line beneath a line of print, then to open his eyes and imagine that he is drawing a thin white line beneath each line of letters on the Fundamental card, as he moves his head from side to side. He is told to blink as he shifts from one end of the line to the other, to occasionally look away and to close his eyes frequently for half a minute or so to rest them. Imagining the white spaces and white line perfectly white causes the mind, eyes to remove the 'grey blur' and other incorrect images from the white page in and around the black letters, words. The brain imagines the page the way it truly appears; clear and white. This causes the letters to be seen dark black, distinct, and clear.

By practicing in this way, letters which could not be seen before appear black and distinct. As one's ability to read is improved, the card is brought closer and the patient is instructed to practice in this way, until the entire card can be read at six inches from his eyes. If it is impossible for him to do this during his treatment at the office, he is directed to practice in this way every day at home. **The patient is told that fine print cannot be read when an effort is made see it and that it can only be read when the eyes are relaxed. For this reason, the reading of fine print is helpful in producing relaxation.**

Take a break anytime and look at the white spaces, thin white line to relax the eyes, mind. Shift on them. Avoid staring, eye immobility.

Use the soft end of a white imaginary feather (nosefeather) to imagine painting the white spaces and thin white line with bright, glowing, pure white paint.

### INSTRUCTIONS FOR HOME TREATMENT

The most important fact is to impress upon the patient the necessity of discarding his glasses. He is told that when glasses are used temporarily a relapse always follows and the patient loses for a short time, at least, everything that has been gained. If it is impossible or unnecessary for the patient to return at regular intervals for further treatment and supervision, he is given instructions for home practice to suit his individual case, and is asked to report his progress or difficulties at frequent intervals.

The importance of practicing certain parts of the routine treatment at all times, such as blinking, central fixation, (shifting, relaxation) and imagining stationary objects to be moving opposite to the movement of his head and eyes, is stressed. **The normal eye does these things unconsciously, and the imperfect eye must at first practice them consciously until it becomes an unconscious habit. An automatic, correct vision habit.**

### Pansy Land

By Emily C. Lierman

[Editor's note - Mrs. Lierman regrets that she has no Christmas story this year, but she has written a fairy story instead, which she hopes the children will enjoy.]

Once upon a time in a town near the Pacific Coast there lived a boy named George who suffered intensely from poor eyesight. One day he met a girl named Christine. The little boy had heard that Christine knew the great secret of good eyesight and begged her to tell him what he could do to cure his eyes. It did not take Christine long to teach George how to use his eyes right and keep from straining them. Christine soon found that George was not lonely like she was, for one day he brought Amy with him, the girl who made many children happy with her stories. She was beautiful to look at and had many friends. George and Amy were constant pals, and helped to make Christine happy. Amy's eyes also became wonderfully bright through Christine's guidance and help, and everyone in Pansy Land wanted to know how this came about.

One day these three friends of Better Eyesight took a trip to the land of pansies. Before they were allowed to enter the gate, they had to seek admission from the door keeper. They waited until he went to see whether or not the pansies had gone to bed, as it was near closing time. He soon came back to them and told them to enter, that the pansies still had their eyes open and would welcome them. They walked a great distance and found that with the exception of narrow paths, everything was covered with miles and miles of pansies. There were yellow pansies with eyes as blue as the skies, brown and tan pansies with rose-colored eyes, and others dressed in all the colors of the rainbow. All of them were swaying with the gentle breeze and they were most beautiful to see.

Suddenly, a jolly gnome appeared before them. They noticed that his eyes were shining brightly and that he had the kindest face of anybody they had ever seen. George knew him right away. He said, "This is Horatio the Great. It is he who first discovered how to cure people without glasses and help those who had pain and other troubles with their eyes." George also remarked that he had the biggest heart that anybody ever had, and was the best friend of poor children all over the world. Horatio the Great stood by, listening to these kind remarks but was too modest to make any reply. He just listened.

After George got through talking, the kindly gnome invited them to sit in his parlor, which was made of the loveliest pink mushrooms imaginable. He told them to place their palms over their eyes and not to think of anything bad or wrong and then to make a wish. They wished that they could be two very little girls and a very little boy again.

All of a sudden, there was a rumbling sound like thunder, and George, Amy, and Christine became very much frightened. The good gnome knew what had happened. He said, "Take down your hands and let me see how badly you have been frightened, when there was nothing at all to be frightened about." He looked into their eyes and said, "Because you were frightened, you began to strain and your eyesight is now bad. You must be calm like I am, no matter how much trouble or worry you might have or how frightened you become. Don't you know that fear always affects good eyes and makes them bad?"

He then told them to again cover their eyes with the palms of their hands and he would tell them what caused their fright. He said, "You know I have many helpers in Pansy Land; some of them are my good gnomes. It was the good gnomes that you heard when they returned to their places on the roof of my palace. Don't be alarmed."

After this remark, there was no more fear and no more eyestrain. He then told them to remove their hands from their eyes. When they opened their eyes again he held in his hand a shining light, which was really a star on the end of a wand. With this he touched their eyelids and they were little children again.

When he touched the lonely little girl he said, "Now your name is Crystal, because you will use the crystal glass with the help of the warm sunshine. You will cure children and grown ups all over the world in time to come. You are ordered to finish your work here on the West Coast of this great big world where many people want you. You must be strong in your mind and heart and know that when your enemies want to hurt you, the good gnome, Horatio the Great, will always be standing by you and will keep you from harm. You must never be afraid."

Amy and George stood by listening with their eyes wide open, but blinking all the time to be sure that they would not strain and displease Horatio the Great.

The good gnome then touched little Amy with the shining star and said, "you will do greater things than you have ever done, now that you have better eyesight and no longer need glasses. You will go to many boys and girls and give them the sunlight with your sun glass. You will take away all pain and sorrow from those who suffer with eye trouble. Sometimes you will go alone, but most of the time little George will take you in his chariot so that you will not be weary in well doing." This pleased little George because he did not ever want to be separated from Amy, who had always made happiness and joy for him. Little Crystal knew in her heart how much they loved each other and this made her very happy.

The kindly gnome, Horatio the Great, then placed his wand with the shining star on the head of little George and said, "My book which tells you how to take care of people's eyes will help you to understand the work that you have to do. What you must enjoy is helping people with bad tummies and relieving eyestrain. I give you my special blessing because of the good work you have already done. You will take Crystal and Amy to your beautiful home in Marston Hills."

This made George very happy. His beautiful home has a frog pond in a lovely garden. In the pond lives one large frog. He has many friends who live near him all the time. Their names are Climbing Rose, American Beauty, Geranium, Calla Lily, Honey Suckle, and many others that would take much time to name.

This kindly frog is never thirsty and is ever ready to share with you the sparkling water that flows from his mouth. Even the frog has his work to do. In the pond directly under the throne on which the frog sits during the day, there lives a family by the name of Goldfish. Not so long ago the family increased in great numbers. They are lively and hungry all the time and Amy and George always feed them. All of the goldfish have perfect eyesight. The frog will tell you that at no time is eyestrain allowed in his kingdom. He has for his kindly assistant, Mary, who looks after things not only in the garden, but in the house that George built.

Horatio the Great led the procession to a little woodland which belonged to the pansies. Little Crystal noticed that a beautiful palm had been crushed on one side and many leaves were scattered on the grassy carpet. The two little girls and the little boy closed their eyes while the gnome told them the story of the crushed palm, and what had happened on that day. He told how the Queen of the fairies had been honored by all the fairies of Pansy Land. No disorder is ever allowed, because it causes much work and strain to those who are the caretakers, but on this special occasion when the Queen of the fairies that live all over the world had been given a reception, he made excuses for the fairies because of the disorder of the place.

From there he led them away to the center of the pansy bed that had the most colors. He told them to palm again and remember the color of any pansy they saw. While their eyes were closed and covered, the good gnome passed his wand with the shining star over the heads of the pansies. When Crystal, Amy and Georgie opened their eyes, low and behold, there was a beautiful fairy on the top of every pansy, right before their eyes. What a beautiful sight it was and how happy these children were. The sun never shone more brightly; never in their lives did they smell more wonderful perfume. Immediately, there was a beautiful fairy dance and the more the children blinked, the more wonderful the fairies danced.

All good things must come to an end, for a little time at least, and soon the kindly gnome remarked that it was bed time for the fairies and the pansies. Horatio the Great, with his kindly manner, led the way to the gate and gently bowed before the two little girls and the little boy, who honored him with their smiles and good wishes and said good bye for awhile.

George remembered what he had promised the gnome, and placing little Amy and Crystal in his chariot, drove on to his home in the hills to the frog pond and the flowers.

Because of their happiness, the good gnome did not wish to change them into grown ups again, so they will always be children and live happily ever after.

## Questions And Answers

Q - Why is it a rest to read fine print? I should think it would be more of a strain.

A - Fine print is a relaxation, large print a menace. The December, 1919, issue of this magazine explains this in detail.

Large print is also seen clear by reading with relaxation, shifting, central fixation.

Q - Must the body be at rest before the eyes can be cured?

A - When the eyes are relaxed, the whole body is relaxed.

Q - Which is more beneficial, the short or the long swing?

A - The short swing, if you can imagine it. - Shift on small letters and see Oppositional Movement - The Short Swing: The letter moves in the opposite direction the eyes shift to.

Q - Are "movies" harmful?

A - No. Quite the contrary. Send for the magazine on this subject.

Q - Trying to make things move gives me a headache. Palming gives me more relief. Why?

A - Making an effort to do a thing will not help you. When you are walking along the street, the street should appear to go in the opposite direction without effort on your part. Some people get more relief from palming, while swinging helps others more.

Q - Why do "movies" hurt my eyes when they should benefit them?

A - Unconscious strain. Do not stare at the pictures, but allow the eyes to roam over the whole picture, seeing one part best at a

time and shift part to part, on objects and from object to object. Also keep things swinging.

Q - Why do some people see better by partly closing the eyes? (Squinting)

A - People with poor sight can see better by partly closing their eyes, but this increases vision impairment and when they have perfect sight, squinting makes it worse. This is a good test for the vision of ordinary objects. (Squinting is a main cause of eye muscle tension, eyestrain and unclear vision.)

Q - Is a hemorrhage on the outside of the eyeball fatal?

A - Rarely.

Q - Is central choroiditis curable and does it require much treatment?

A - Yes, choroiditis is curable but requires a great deal of treatment in some cases.

Q - My trouble is cataract. Shall I cover up the good eye while practicing?

A - Practice with both eyes together until your vision is normal. Then, cover the good eye and improve the vision of the poor one.

Q - Is it necessary to practice with the Snellen test card if you follow the method otherwise?

A - Yes, it is advisable to keep up your daily practice with the test card for at least a few moments. This will improve your memory and the memory must be improved to have the vision improve.

Practicing with both eyes and one eye at a time with the card also keeps perfect, equally clear, balanced vision in the left and right eyes. The Snellen card is also a familiar object. Looking at a familiar object relaxes the mind, eyes and keeps vision clear.

## Announcement

For the benefit of school teachers and school children, the Numeral and F cards, regularly listing at 50 cents will be sold at 25 cents during the months of December and January; fundamental cards regularly listing at 10 cents will be sold at 5 cents. We also wish to call our readers' attention that the following back numbers of "Better Eyesight" will still be sold at 10 cents per copy during the months of December and January.

Here Dr. Bates lists back issues.

The issues are included in this book.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JANUARY, 1928

### Eyestrain During Sleep

Many people complain that when they awaken in the morning, they are suffering from pain in their eyes or head. They often feel as weary as though they had been working hard all night long. Many of them do not recover from the pain and fatigue until after they have been up for an hour or longer. Their vision also may be found to be reduced to a very considerable degree. Some complain that they see illusions which are occasionally very slow in disappearing. One patient complained that the tiled floor of a bathroom had a very strange appearance; although the tiles were white, to him they appeared blue and red alternately. A feeling of strain was always present and did not subside until the illusion had disappeared. It seemed as though the eyes were under a strain during sleep, because when the eyes were examined with the ophthalmoscope while the patient was asleep, a strain could readily be observed.

Sometimes, as in the case of many children, other parts of the body may be under a strain during sleep. By an unconscious effort, the muscles of the face, arms and limbs may be distorted as may be muscles of different parts of the eyeball. In some cases, the strain produces accommodation or myopia, while in other cases, hypermetropia or astigmatism are produced by this unconscious effort. These eyes frequently were found to be normal during the day.

The treatment to prevent eyestrain during sleep is not always successful. Some patients obtain most relief by practicing the **long swing one hundred times or more just before retiring and the same number of times in the morning immediately after awakening**. Other patients find that **palming for twenty minutes before retiring** is a help, and frequently the palms are left in place with benefit after the patients have lost consciousness.

## Glaucoma

By W. H. Bates, M.D.

Glaucoma is a serious disease of the eyes which some years ago was considered incurable when chronic. In most cases, the eyeball was usually too hard and this is the symptom which more than any other was the strongest evidence we had that the eye was suffering from glaucoma. The field of vision was contracted on the nasal side and the pupil was usually more or less dilated; the cornea was not as sensitive as the normal eye. Sometimes the anesthesia, or that condition in which the cornea is not sensitive to the touch of a blunt pointed instrument, was quite marked. One characteristic symptom was the apparent appearance of colors around the flame of a candle or some other similar light.

Glaucoma is a disease of adult life and seldom occurs in children. Its uncertainty is unusual. For example, a person with normal eyes and normal sight may retire feeling perfectly comfortable. Sometime in the middle of the night, he may be awakened by a very intense pain, with total permanent blindness in both eyes from glaucoma. In a limited number of cases, pain may be absent, although the vision may be partially lowered. The sudden onset may not occur, but one or both eyes may slowly, without pain, after a long time, a year or longer, become totally blind.

In the American Encyclopedia of Ophthalmology, the article on glaucoma consists of 170 pages of solid type, describing facts connected with the symptoms, cause and treatment of glaucoma. These facts are so numerous that the writer did not have to repeat himself. He emphasized how little ophthalmologists actually knew about glaucoma. It is evident that many theories cannot all be true.

One authority claimed that the cause of glaucoma was connected with a loss of the iris angle (that part of the eye which is located at the outer part of the iris), when a formation of new tissue, resembling scar tissue, formed in the iris angle and acted as a sort of plug preventing the proper circulation of fluids of the eyeball, when there was less fluid in the front part of the eyeball than is found in the front part of the normal eye. Many cases were benefited by an iridectomy, an operation in which a portion of the iris is removed. This theory went the way of some of the others when numerous exceptions were observed.

Another authority claimed that dilation of the pupil was an important factor in the cause of glaucoma. However, many cases were found in which the pupil was contracted as much, and in many cases more, than in the normal eye.

The results of the various methods of treatment which were suggested and practiced have been so disappointing, that we hesitate to foretell what may happen after any of them have been practiced.

It was a very welcome discovery made by my assistant, Ms. Lierman, that the relief of eyestrain always lessens tension, relieves pain and improves the vision. **The discovery that relaxation methods cured glaucoma suggested that the cause was due to eyestrain.** Experimental work proved this to be true. **All methods of treatment which promote relaxation always benefit glaucoma.** When the vision is good, a stare or strain or an effort made to see, brings on an attack of glaucoma. It is a difficult thing consciously to produce glaucoma by an effort to see. It is much easier to relax and benefit glaucoma. The writer has always felt great satisfaction in convincing patients that in order to have glaucoma and blindness, they had to go to a lot of trouble, work hard, and strain in order to produce it, but to benefit glaucoma was easy and required no effort whatever.

## Treatment

By seeing one part of a letter best and all the rest of the letter not so well (central fixation), the letters of the Snellen test card appear improved to the maximum. Sometimes one has trouble in imagining central fixation of all the letters. On a card at fifteen feet, a patient with glaucoma could not imagine the letter "F" by central fixation, but the figure "6" of the same size and at the same distance was imagined by central fixation quite readily. The patient became able to imagine a period on the top of the figure "6" and the rest of the letter appeared worse. Usually, however, when looking at the letter "F," a period could not be imagined on any part of it. Sometimes, however, after the figure "6" was seen by central fixation, the patient could, by alternately shifting from the "6" to the "F," imagine the letter also, by central fixation. I might say that there were times when the figure "6" was an optimum and the letter "F" a pessimum. Then, there were other occasions when the figure "6" was not an optimum and the symptoms of glaucoma were variable, changing, increasing, and diminishing. It is well to remember this truth, because when the patient found which letter was an optimum, or could be seen by central fixation, he was enabled to improve his vision for other letters, together with simultaneous improvement in the glaucoma.

Some of the **best methods of producing relaxation are the practice of the long swing, the variable swing, the sway, palming and sun treatment.** There are some people who cannot practice a certain swing correctly until after weeks of instruction. They are full of excuses and are quite ready to find fault with the method rather than with their own lack of practicing properly. (The above mentioned methods have been described from time to time in previous issues of the magazine.)

Glaucoma may be produced solely by the memory of imperfect sight. If a person with normal eyes and normal vision presses lightly on the eyeballs through the closed eyelids and remembers or imagines a letter "O" with a gray, blurred outline very imperfect, the eyeball can be felt to increase in hardness. When the patient remembers a letter "O" perfectly, the hardness of the eyeball disappears and the eyes become normal as they were before. **These experiments are offered as proof that the memory of imperfect sight is a strain which may produce glaucoma, and the memory of perfect sight a relaxation, which will relieve glaucoma.** When the eye shifts, moves and uses central fixation the eye has normal softness and pressure.

One patient with acute glaucoma together with cataract could not distinguish 10/200, or the large "C" at the top of the Snellen test card. By looking at a light off to one side and flashing 10/200 alternately, the vision improved almost immediately to 10/30. She was able to remember the light when regarding the Snellen test card for a few seconds only. By alternately looking at the light and regarding the Snellen test card, her memory for the light improved, while her memory for the letters of the Snellen test card also improved.

She seemed to need supervision, because when practicing by herself, she did not flash the letters or look at them for a moment only. She stared at the light and the Snellen test card and instead of her vision improving, it became worse and it required encouragement to induce the patient to flash letters or other objects.

The memory was also improved by the practice of central fixation. When she looked at the first letter of a line of letters (placed in the center of the visual field) on the Snellen test card, she saw the other letters on the same line (in the peripheral field) not so well; the memory of letters and other objects seen by central fixation became very much better in a short time. The patient's memory was also improved by the imagination of the halos, that is, when she regarded a white center of a letter "O" and imagined that she saw it whiter than the rest of the card, her memory and the halos also improved.

Close the eyes and lightly touch the eye through the upper eyelid.  
+Imagine a letter O imperfect, blurred and feel the eye increase it's hardness.  
+Imagine the O perfect, clear and feel the eye return to normal softness and pressure.

## Case Reports

### CASE ONE

A woman, fifty years of age, was suffering from **retinitis pigmentosa**, **incipient cataract** and **chronic glaucoma**. After daily treatment for six months, the vision was improved from 10/200 to normal. **Palming, shifting** and **swinging** gave the best results. She acquired the habit of imagining stationary objects to be constantly moving. The objects in her rooms, the furniture, window shades, the rugs, the ceiling, in fact all stationary objects seen could be imagined to be moving whenever she moved her head and eyes. Alternately **looking at the sun** and stationary objects in the house improved her sight. When she was out of doors, she imagined the sidewalk to be coming towards her, or if she looked to one side, that the buildings or other objects were moving in the opposite direction. (Oppositional Movement)

Another method which helped her was to stand before a window and imagine the curtain cord to be moving in the opposite direction as she **swayed her body from side to side, while a building in the distance appeared to be moving in the same direction as the movement of her body**. Oppositional Movement = When moving the eyes, head, body left, right, up, down, any direction: close objects appear to move in the opposite direction, distant objects appear to move in the same direction the eyes, head, body move to and close and distant objects appear to move against each other in opposite directions. Distant objects actually appear to move opposite but move so slow in the opposite direction that they appear to move in the same direction the eyes, head, body are moving to. The function of oppositional movement helps the brain determine depth, distance, placement, space of objects at different distances, dimension, 3-D vision, binocular vision, fusion, ability to calculate the time it takes to travel to, from a object... and other functions of the brain, body, visual system.

It was very interesting to observe that the pigment spots of the retinitis pigmentosa were disappearing from view; the symptoms of glaucoma also disappeared gradually. **When she remembered perfect sight, one could, with the ophthalmoscope, see the cataract immediately becoming less. When she remembered imperfect sight, the cataract became very opaque.** Besides obtaining normal sight for the distance, she became able to read diamond type at six inches without glasses.

In the beginning of the treatment, the left eye was the better eye. However, the left eye was treated for more than six months before normal vision was obtained, while the vision of the right eye improved from 10/200 to 20/20 after only one week of treatment.

This patient was very grateful for the benefit she received and could not understand why many of the ophthalmologists whom she had consulted previously did not refer her to me. Her constant question was: "If these other doctors could not cure me, why did they not send me to the doctor who could?"

### CASE TWO

A physician had been in the habit of attending a gymnasium and after he had finished with his exercises he usually bathed in the pool. The exercise and the bathing seemed to agree with him perfectly and although he had been taking these baths almost daily, no injury to his eyes could be detected. One night he was awakened by a severe pain in both eyes, which stopped only after the use of morphine. In the morning he was practically blind.

The doctor whom he consulted said that he was suffering from **glaucoma** and **iritis**. The iris was inflamed and the pupil opaque from the presence of inflammatory exudation. The eyeballs were very hard. This severe inflammation continued for more than six months. Accidentally, he heard of my method and came to see me, very hopeful. He told me, after relating the above, that he had had my book read to him and that he had felt decidedly encouraged.

Upon examining him, I found the eyeballs very hard, his field of vision contracted more on the nasal side than elsewhere; the pupils of both eyes contracted and his sight reduced to 1/200. He asked me if I thought that his eyes had been infected or if he had injured his eyes by striking the water when he dove into it. I told him that I did not believe that had anything to do with it, and that his trouble was brought on by mental strain.

The patient was advised to practice at home those measures which had already improved his sight while he was at my office, **palming, swinging** and **sun treatment**. At his second visit, a few days later, he was further encouraged. The redness of the white part of the eyes had entirely disappeared. The pupil was no longer contracted, but was dilated to the same extent as is found in most normal eyes.

He was much pleased that the **sun treatment** had been of marked benefit. He said that he had read in many eye books that persons suffering from iritis should protect their eyes from the injurious effects of the light by wearing dark glasses. He also said that he was convinced that the sunlight and other forms of light were a benefit to his iritis and not an injury.

His condition continued to improve, and in a few days he was able to read the large type of a newspaper without discomfort. I said to him: "why don't you read the small type?" He answered that he was afraid he would strain his eyes. My answer to this was to hand him a card on which was printed some sentences of **diamond type**. He was able, much to his surprise, to read the diamond type at about six inches. This amused him so much that one could hear him laughing almost a block away. He compared his ability to read fine type with his ability to read the large type of a newspaper and found that the diamond type was easier. He said: "Why is it that I see the diamond type easier than I do the large print?" I replied that it was because **in order to read the diamond type, his mind had to be relaxed. If he strained, he could not read it.** If he could not read it, he strained. He was advised to read as much diamond type as he had time for.

The patient was encouraged to keep up the treatment until a complete cure was obtained.

## A Case Of Absolute Glaucoma

By Emily C. Lierman

This article contains descriptions, directions for a variety of Bates Treatments

A man, aged 68, with absolute glaucoma was brought to me by his physician, who was quite sure that the Bates Method could do nothing to restore his sight. This man had had three operations on both eyes; the first operation was performed in the year 1924. He had no perception of light in the right eye and could see but very little with his left eye, not more than 1/200. The doctor who brought him was the most skeptical person I have ever come in contact with. His manner in regard to the method was almost insulting, and I resented his attitude very much. I had a conversation with him over the telephone previous to the appointment which was made with his patient. He was to give me an hour with this man, and if at the end of that time I could improve the patient's sight, even a particle, he would believe that Dr. Bates was right when he claimed that glaucoma was curable by his method.

I never felt more determined in my life to do the best that was in me for this patient. Before the hour of his appointment, I sent him my book, "Stories from the Clinic" by special messenger to him and asked him to read what I had written about the relief of strain in glaucoma.

When the doctor entered my office with his patient, one could see by his face that he was ready to prove that his patient would receive no benefit in his sight. I was in a fighting mood myself and my eyes, I feel sure, told him of my determination to prove that he was wrong and I was right. I informed the doctor immediately that even though his patient was a wealthy man, I would not accept a fee at this time, but if the patient received further treatment from me or from Dr. Bates, he would have to pay a bonus in advance besides the regular fee, for the hard work which would be before us. As I look back upon that day and hour which I spent with his patient, I realize how hard I worked.

The right eye, as I have said, had no sight at all because the retina was almost destroyed and there were other complications caused by the operations. Because of this, it was not necessary for my patient to cover his right eye while the left eye was being tested.

I produced the **white test card with black letters**, as the patient sat by a window with the **sunlight shining on the whole card**. I watched to see what effect the strong light reflected on the card would produce. Immediately the patient drew back, as if the strong light hurt his sight. I was pleased to note this, as I knew then that the patient was sensitive to the strong light which, of course, was in my favor, because **sun treatment would overcome this sensitiveness and probably improve the vision**. The doctor made no comment. At one foot from his eyes, the patient could **flash the 2 (200 line) letter "C" as he moved the card slowly from left to right before his eyes**. More than that, he could not see without causing a great deal of effort. Then I changed the card and replaced it with the **black test card with white letters**, placing the card in his hand as I had the white card. I directed the patient to **keep the card moving slowly from side to side and to blink as he moved the card**. By doing this, **he flashed the 100 line letters, one at a time**. Occasionally, I glanced at the doctor's face to see whether he was pleased or not. He might have been a sphinx for the lack of interest which he showed.

My next plan was to have the patient **palming**, which I told him how to do, and while he was palming, I asked him to **tell me what interests he had in life**. He said he was a banker, so I advised him to **remember figures on bank notes as well as he could; also to remember other things in regard to the work which he is most interested in**. I avoided any unpleasant conversation regarding his eye trouble, which he unconsciously referred to from time to time.

I explained to him that his poor sight worried him more than he realized, but if he believed in what I was trying to do for him, he would not feel so hopeless in time to come. Jokingly, and half in earnest, I remarked, "You must have a better attitude of mind than your doctor has at the present time," which brought for the first time a smile to the face of the doctor. The patient said he was willing to believe that I could help him and I know that he meant it.

While the patient was palming, **I placed the large black test card with white letters upon a test-card stand, which I arranged five feet from where the patient was sitting**, and in an ordinary light. Again I looked at the doctor, but he made no sign of being in doubt or otherwise. This would have been discouraging, I know, to most of our students, but I have had so much experience with people like him, that I paid no more attention to him than if he were not in the room. It was the only way for me to keep from either weeping or gnashing my teeth.

After the patient had palmed for more than ten minutes and had removed his hands from his eyes, I asked him to stand. As I held both his arms at the elbow, I asked him to **sway from side to side** with me. Of his own accord the patient remarked, with a smile, how relaxing it was to sway his body, and that he enjoyed doing it. At first he did not recognize the card where I had placed it, and I myself did not mention to him what I had done while he was palming. I told him that he was to **keep up the swing of his body until he discovered the test card and was able to read some of the letters**. I also informed him that he was **not to try hard to see any letter, but to keep up the sway**.

Anyone interested in our work can imagine how happy I was to hear him say, "I think the middle letter of the third line is an 'O'." Before I allowed him to go any further, I told him to **sit down again and palm**. I felt that the palming had had as much to do with the improvement in his sight as did the swinging of his body. While the patient was **palming**, I told him to **remember anything which was pleasant**, that it did not matter much what it was. Some patients enjoy remembering a **sunset**, or a **white cloud in a blue sky**. I reminded him of these things and also told him it was necessary for him to **shift from one thing to another and not to concentrate on any one thing**.

While he palmed, he said that he had had a bad habit for years of concentrating or trying to concentrate, which he thought was beneficial, but now realized that this produced more strain and discomfort. It was nice to hear the patient explain these little things to me, because it proved to the doctor who brought him that he was anxious to help me in what I was trying to do for him. This time the patient **palmed for about fifteen minutes** and then we started the **standing sway of the body**, having him **blink regularly** as he did before. This time, **he read every letter of the 5 line** (also called 50 line on other eyecharts), **seeing one letter at a time and looking away quickly to avoid staring**. A great feeling of satisfaction came over me as I saw that the doctor was watching the patient closely. Nothing was said, however, because we both felt the need of silence at this time.

The patient began to strain unconsciously to read the next line of letters, but I avoided having him read any further until he had **again rested his eyes by palming**. This time it was not necessary for me to again remind him to **use his memory**, for he immediately mentioned how **white the letters looked on the black background when he did not look at the card longer than a fraction of a second**: I said that it was a good thing for him to **alternately remember the black margin of the card and then remember the white letters as he saw them**, or if he possibly could, **without an effort, to imagine the letters whiter than he really saw them**. After he had rested his eyes in this way for ten minutes or longer, I placed him in the **sun**, and with my **sun-glass** I focused the strong rays on his closed eyelids. Some patients draw away when they first receive the

sun treatment, but this patient enjoyed the strong light of the sun from the start, which made it easier for me to treat him.

After the sun treatment, he again read the test card at the same distance, and this time, he read all of the 3 line. (30 line) The patient turned to me and thanked me for my efforts and for what I had done for him. He also told me that he would **try to do without the strong magnifying glass which he had been using for a few years to help him in his work. I explained how dangerous it was for him to continue the use of the magnifying glass even though it helped him to see things better at the time.** As this patient had never heard of the Bates Method before, I am not sure that he realized the importance of what I explained to him. I really helped him and improved his vision from 1/200 to 1/6 of normal in one hour's time under unfavorable conditions, for which he was grateful.

As the time for the treatment was over, I had to let the patient go, but I had satisfied the skeptical doctor who not only fought me with his mind, but also tried to prove to me that Dr. Bates' statements were false when he claimed to relieve tension in glaucoma and also improve the sight when other methods had failed.

I never saw this patient again, because he lived a great distance from my office, but I feel sure that the doctor is no longer skeptical, but is at this time helping others in the cure of imperfect sight without glasses.

## Questions And Answers

Q - I have a high degree of myopia. Approximately how long will it take to obtain a cure by your method?

A - It is impossible to say, as people vary so in their response to the treatment.

Few minutes, hour, day, week, month, year - depending on the individuals type/amount of strain, understanding and correct use of the Bates Method.

Q - How often should one with imperfect sight palm during the day and for how long?

A - Palming should be done as often as possible during the day, ten times at least, for five, ten, fifteen, minutes or longer at a time. Some people obtain more benefit from short periods than from longer periods.

Q - Am forty-nine years of age and have had to wear glasses for five years, due to gradual weakening of the eyes. Is this curable?

A - Old-age sight is curable, and you can discard your glasses by following the methods as outlined in the book, "Perfect Sight Without Glasses."

Q - If one's arms become tired while palming, will a black silk handkerchief covering the eyes produce the same amount of relaxation one gets from palming?

A - No. Palming is the best method for relaxation and improvement in vision. When tired of palming, the hands can be removed and the eyes kept closed until one feels relaxed.

Q - Can the vision be improved without glasses after the lens has been removed for cataract?

A - Yes.

Q - Can squint (crossed, wandering eyes) be cured by treatment without glasses after an eye muscle operation proved unsuccessful? Does age make any difference?

A - Yes. Age does not make a difference.

Q - Will it still be necessary to continue practicing the method of swinging and shifting after my eyes are cured?

A - No. When you are cured of eyestrain you will not be conscious of your eyes. However, if you strain them, you will know what to do to relieve the strain.

Q - Is it a strain to the eyes to read while riding on a train?

A - No, if there is no discomfort. It is a good thing to look out of the window and see the scenery moving in the opposite direction to that in which you are going, and then continue to read. (Oppositional movement)

Q - What causes and cures abnormal watering of the eyes?

A - Strain produces watering of the eye. Relaxation obtained by palming and swinging will cure this trouble.

Avoid sunglasses, tinted, colored, UV blocking lenses, eyeglasses, contact lenses.

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

FEBRUARY, 1928

### The Thumb Movement

**Rest the hand against an immovable surface. Place the ball of the thumb lightly in contact with the forefinger. Now move the end of the thumb in a circle of about one-quarter of an inch in diameter. When the thumb moves in one direction, the forefinger should appear to move in the opposite direction, although in reality it is stationary.** In the practice of the universal swing, everything is imagined to be moving in the same direction, except the eyes. With the aid of the thumb movement, however, one can imagine the spine and the head moving opposite to the direction of motion of the thumb, while the eyes, being fastened to the head, also move with the head and hand.

While watching the movement of the thumb, remember imperfect sight. At once, the thumb movement becomes irregular or may stop altogether. Demonstrate that any effort, no matter how slight, to see, remember or imagine, interferes with the movement of the thumb. The thumb is so sensitive to an effort or strain that the slightest effort is at once recorded by the motion.

While watching the movement of the thumb, remember perfect sight. Notice that the movement of the thumb is slow, short, continuous, and restful - with relaxation of all parts of the body.

Many patients have been successfully treated for pain, fatigue, and dizziness with the help of the thumb movement, after other treatment had failed. Some patients with severe pain complain that when they forget to practice the movement of the thumb, the pain comes back.

Not only have patients suffering from pain and symptoms of fatigue been relieved, but an equal number have been relieved of imperfect sight by the correct practice of the thumb movement.

Thumb movement done in various directions and with the left and right hands also activates, integrates the left and right brain hemispheres and eye movement, shifting.

Move the thumb on the stationary finger tip in a 1/4 inch circle. Move clockwise for a while, then counter-clockwise. Move the thumb left and right, up and down... against the finger. Practice with left and right hands.

### Fact And Fancy

By W. H. Bates, M.D.

The attention of the editor was called to a copy of the "British Medical Journal" of October 8th, 1927, page 641, in which my discoveries on the cure of imperfect sight without glasses were adversely criticized. The following is the article in question:

"There are some who deny that the world is round, and some who still believe in the mystery of Joanna Southcott's boxes, so that it is not altogether a matter of surprise that there are others who deny the facts of physiology and of experience. There is a book before us, written by one W. H. Bates, M.D., which for boldness of denial and strangeness of assertion rivals the others. The title of the book is 'The Cure of Imperfect Sight by Treatment Without Glasses.' but that on the cover is 'Perfect Sight Without Glasses.' The author would have us throw away our useful glasses, and beguile ourselves into the belief that we see better without them. Trail shows that we do not and that his alleged treatment is no more than a beguilement that does not stand the test of experience. To practice judgment of what is seen is one thing, to see that same thing better is another. To 'palm' the eyes - otherwise make use of familiar and refreshing massage - is one thing; to alter anatomical defect another. But then this author denies anatomical facts and alleges that all errors of refraction are merely functional. Strangely enough, he admits the use of glasses for patients who have no lenses as the result of cataract operation but denies the use of the lens in accommodation, despite the evidence of Purkinje's figures, which he has heard of, for he reproduces the classical picture in his pages. His cult extends to the assertion of the value of small print, even that which is so small that it cannot be read: 'those who cannot read such type may be benefited simply by looking at it.' Excessive light, he alleges, is not injurious, but actually beneficial; therefore look open eyed at the sun. Reading in bed is 'beneficial rather than injurious' - perhaps when the print is not seen! But, strangely, black has its virtues: 'It is possible to perform surgical operation without anesthetics when the patient is able to remember black perfectly.' Perhaps the author got somewhere near a truth in a sentence in the last paragraph of this book: 'The fact is that, except in rare cases, man is not a reasoning being.'

"We met one of this cult recently; a parent had been summoned to attend a certain place owing to his persistent refusal to provide his child with glasses for school use. The child had myopia of 3 D; without glasses vision was 1/60, with glasses 6/6. The child appreciated the value of the glasses, but the father would not allow them to be worn, alleging other treatment. But the recalcitrant parent wore glasses himself for an equal degree of myopia. It seems a pity good paper should be wasted on such a book, or that our columns should give space to its notice. But there have been inquiries and so this review."

"There are some who deny that the world is round" and we hold such misguided ignorant people more or less in contempt, because they appear to ignore the learning of other people who are very highly respected for their scientific knowledge. It so happened that an ignorant man said to me: "Doctor, do you know that they found out that the world was not round?" I answered, "No, I had always believed that it was round." "Well," he said, "my boy came home from school one day and told me that the earth was flattened at the poles," and then he showed me his son's geography. The book stated very clearly that the shape of the earth is not a perfect sphere, but because it is flattened at the poles, it is an oblate spheroid. Since then I have not learned that the man was persecuted who called the earth an oblate spheroid and published the facts in a book which was used as a text by school children all over the world.

Reference has been made to Joanna Southcott by my worthy critic, and he probably suggests that I am no better than she. I looked up the history of Joanna Southcott and found that she was a domestic servant born in Devonshire, England. She joined the Methodist Church in 1790 and in 1792 announced herself a prophetess giving forth revelations. At one time she sold 6,400 sealed packages or boxes warranted to secure salvation to the purchasers. She prophesied that she would give birth to Shilo or the Prince of Peace on a certain day, but failed to do so.

I deny that I ever attempted to beguile anybody into an error. When a patient comes to me wearing glasses, I usually test his

vision without glasses and tell him that the treatment consists of eye education for the purpose of improving his sight so that he can, without glasses, see as well as, or better than he can with them. It never occurred to me that any of my patients would call this beguilement. The word, however, is a good one and may be useful in the future as a substitute for the word imagination. My practice is built up by the recommendation of patients whom I have cured without glasses.

If my critic had read the chapter on palming more carefully, he would not have made the mistake of calling it massage.

I have been criticized for denying an anatomical fact. I do not deny that in myopia, the eyeball as well as the optic axis is elongated; that in hypermetropia it is lessened; that in astigmatism its form may be modified, or that in presbyopia, glasses improve the vision. Eyeglasses for presbyopia, close vision quickly increase vision impairment at all distances resulting in stronger and stronger eyeglass lenses. My book describes how errors of refraction are curable and have been cured by eye education. The cause is an effort or strain. When this effort or strain is corrected, all errors of refraction disappear and the patient becomes able to see as well, if not better, without glasses than he formerly did with them.

When a patient with normal eyes and normal sight regards a blank surface and makes an effort to see, an error of refraction can always be produced and demonstrated with the aid of a retinoscope. When a patient with imperfect sight looks at a blank surface without trying to see, the retinoscope demonstrates that the error of refraction has disappeared temporarily or more permanently. It is a fact that it is possible to teach patients, who have progressive myopia of 16 diopters, how to cure their myopia by relaxation. What is true of myopia is also true of hypermetropia, astigmatism and presbyopia.

Although some years ago I usually prescribed glasses for the benefit of the sight after cataract extraction, I do not do so at the present time. With the aid of eye education, such patients become able to read diamond type without glasses at six inches or nearer to their eyes or eighteen inches or further. These facts are offered as evidence that the lens is not a factor in accommodation, because the eye can change its focus within wide limits after the lens has been removed.

In my investigations, the figures of Purkinje were studied. For some years, I tried to obtain a perfect image, reflected from the front part of the lens, which was sufficiently clear and distinct to be photographed or measured accurately. The pictures I obtained were very much blurred and one could draw wrong conclusions from their behavior during accommodation, as well as imaginary ones which "proved" a great many theories. In short, one may say that as a result of studying these blurred Purkinje figures, almost any explanation of how accommodation was brought about might be imagined erroneously. Helmholtz was not satisfied with the pictures he obtained by photography, and his illustrations of the behavior of the images of Purkinje were usually in the form of diagrams, which I do not consider good evidence of the truth of his conclusions. My book has described the work of Helmholtz in this field and I would respectfully offer that to the reader's consideration for criticism.

About a year ago, a friend living in England attended a meeting of one of the optometric societies. The speaker of the evening considered the cause of accommodation. He obtained photographs of the reflection of the image from the front part of the lens before and after accommodation. I was very glad to receive these photographs, but was very much disappointed when some experts who were taking moving pictures for me pointed out that the photographs of the optometrists were retouched.

While working in a physiological laboratory, the director suggested that I repeat the experiments of Helmholtz on accommodation, with the end in view of finding out how he made his mistakes. This seemed a very difficult problem to solve. After some years of hard work I became able to obtain photographs of images reflected from the front part of the lens both before and after accommodation. These images were clear and distinct and furthermore I learned how to arrange an apparatus by which an observer could see a clear image reflected from the cornea, iris, the front part of the lens, the front part of the sclera and from the different parts of the outside of the eyeball. There was no change in the image reflected from the front part of the lens during accommodation.

The director of the laboratory was able to demonstrate with his own eyes, with the aid of this apparatus, the truth that the lens is not a factor in accommodation.

#### Helmholtz Theory

The great trouble with the physiology of the eye is that most of us feel that after a man like Helmholtz finishes a job, that it is not possible that he has made any mistakes. I believe that he has made a monumental blunder and I do not hesitate to say so. Helmholtz was a great man and he helped things along very well, but his "Physiological Optics" has almost spoiled everything else that he wrote. Someone has said that the pupils of Helmholtz were thoroughly convinced that the lens is the only factor in accommodation, while he himself was more conservative. **In short, he published a statement to the effect that he did not prove that the lens was the only factor in accommodation.**

My critic says; "His cult extends to the assertion of the value of small print, even that which is so small that it cannot be read, 'those who cannot read such type may be benefited simply by looking at it'." People with imperfect sight are benefited by looking at fine print, provided no effort or strain is made. I recommend this treatment to my critic if he is suffering from presbyopia.

"Excessive light, he alleges, is not injurious, but actually beneficial, therefore look open-eyed at the sun." It is very wonderful how much the vision may be improved by sunlight, also by some forms of electric light. It does not naturally follow that I believe looking directly at the sun is indicated. People with normal eyes are able to look directly at the sun without discomfort, whatever, provided that no effort is made, while others with imperfect vision are made worse temporarily. Shift, move the eyes (do not stare) when looking at/near the sun.

Swing the child in a circle counter-clockwise, clockwise... to correct squint.

Rock the baby gently, with love, side to side, up and down...

Rocking Cradle-sideways

Rocking cradle - forward

Baby rocks his own way!

Movement keeps the body, mind healthy, eyes relaxed and vision clear.

Kids love action, movement, adventure! Sliding in the snow is a form of the Swing.

"Reading in bed is beneficial, rather than injurious." Reading in bed without effort is a benefit. If one makes an effort while reading, it is an injury.

It is a fact that it is possible to perform a surgical operation without anesthetics when the patient is able to remember black. I have repeatedly operated on the eyes and other parts of the body painlessly when black was remembered perfectly.

The patient whom my critic mentioned who wore glasses for myopia and denied the same practice to his son is certainly open to criticism.

I do not see why my critic has published so much against me without a proper scientific investigation, and without conclusive evidence that I am wrong. If John Doe says that myopia is incurable, before accepting this as true, we would like to know what his evidence might be. In my book are published many facts which are of sufficient importance, I believe, to be investigated. My critic has said very little about the evidence which has been offered there by me to prove that my statements of the truth are correct.

Just today a patient came to me with a diagnosis of **chronic glaucoma** and told me that the best doctors in this country had advised an operation at once. In my experience, chronic glaucoma does not respond favorably to any operation. This patient was treated by relaxation or rest and obtained normal vision, without glasses, for the distance and became able to read fine print, diamond type (Jaeger No.1) at six inches. She was very grateful for the relaxation obtained and was overjoyed to find that an operation was unnecessary. This case is suggestive and the temporary or permanent cure which she obtained in one visit was a fact that no amount of contradiction can modify or lessen.

Children less than three years of age, too young to learn the letters of the alphabet, have been **cured of squint by practicing the swing. Let the mother or father or some member of the family with whom the child associates give the child confidence. They should take hold of both hands of the patient and swing him around and around until his feet are lifted from the floor.** The child enjoys this immensely after he has practiced it for a few times. Frequent swinging of the child for a few minutes during the day usually cures squint, divergent, convergent, or vertical - at first temporarily and later on more continuously or permanently. It does not require an ophthalmologist to observe the benefit.

**Children less than a year old who are suffering from tension with many forms of eye disease, are relieved of their tension by rocking them in the arms of the mother and by the use of an old fashioned cradle.** I believe that the eyes of children are more frequently diseased at the present time than they were when the cradle was used. It should be emphasized that **motion is a benefit, not only to children but also to adults.** Adults can use a rocking chair, swing...

All through my book are reports of cases in which patients have been blind from one or more of the numerous diseases of the eyes. They were all benefited by the relaxation treatment. When they recovered and became able to see without glasses, no amount of criticism without facts could shake these persons' faith in my methods.

## Individual Treatment

By Emily C. Lierman

During my year's experience treating patients in the West, I came in contact with a number of patients who were treated, but not benefited, by those who did not properly understand the method. I finally stopped counting the number of patients who came to me for the relief of presbyopia, cataract, glaucoma and other troubles. I shall try to describe the worst case among all these patients who appealed to me for the relief of pain, so that the readers of our magazine and others will know the truth about things.

One or two so-called doctors or specialists were directly responsible for the pitiful condition of this patient. There was so much wrong with this man that I hardly knew where to begin. This was his story, related before I tested his vision with the test card:

Up to the time he was twenty-five years old (he was now 51) he had good sight for the near point as well as for the distance, but soon after that he found difficulty in reading ordinary type, unless he used a strong light. He decided to wear glasses for reading only and got along with them for a short time. Then his eyes began to smart and pain when he was out in the sun and his sight for the distance became very blurred. He suffered with headaches almost every day for a while and finally was advised to have his glasses changed. Two pairs of glasses were prescribed for him by one eye specialist, one pair for reading and the other for his distant vision.

He said he was faithful to the doctors who from time to time had given him eyeglasses, as he wore them constantly every day for some years. He finally discarded glasses altogether because he found no relief from pain. After obtaining Dr. Bates' book, "Perfect Sight Without Glasses" and receiving some benefit from what he practiced, he decided to try the complete treatment. He went to a doctor whom he understood gave the Bates treatment, although at this time he was not informed so by the doctor. He had to pay a sum of money in advance for a course of treatment which ended in the spring of the year. By that time his condition was worse than it was in the beginning.

He was told that if he would take another course of treatment, he would surely be cured, and as an inducement he was told of special summer rates of which he ought to take advantage. What a tale for the ears of Dr. Bates!

The patient, however, submitted to another course of treatment, hoping to be benefited. After another month of this treatment, with his condition of health getting worse every day, he found out for the first time that the treatment was not the Bates Method. He questioned the assistants who helped in the treatment if Dr. Bates used all the apparatus and eye muscle exercises that were given him there and he was told by the doctor that the treatment was his own discovery and not the Bates Method. What a pity that he had not been informed of this in the beginning!

On the 20<sup>th</sup> of July of the same year this patient came to me and the nervous twitch of his shoulders as he talked made me nervous too. It took just one hour for the patient to explain to me just what I have written about him. He not only stuttered but some words were so long drawn out that it took considerable time. He did not blink, but stared all the while he was talking. However, when he finally did blink consciously or unconsciously, I noticed that the nervous twitch of his shoulders subsided.

The patient emphasized the fact that as far as seeing ordinarily, his vision was not bad. The treatment which he had previously received was not a benefit but an injury to his nervous condition. The daily electric treatment, with osteopathy, colored lights and hypotherapy, whatever that might be, was the cause of his nervous symptoms. When he explained the treatment to his friends who had known him for many years, they were convinced, as he was, that the treatment had made him worse instead of better. He told me that other patients as they came to this practitioner for daily treatment were more or less thrilled and impressed because so much was given them for their money. Those who came to me later were shocked to think that so little was given them in the way of treatment for their money and it seemed difficult for them to believe that they could be benefited.

Before I tested his sight with the test card, I made him promise to help me, because at that time I did not know whether or not I could do anything for him. His vision with the test card was normal, 15/10 with the right eye and 15/15 with the left, but the letters were a little blurred. I directed him to **palms**, which he knew how to do, but I noticed while he was palming that his shoulders twitched continuously all the while he had his eyes covered. After palming for about ten minutes or a little less, the 15-line of letters still looked blurred to him with the left eye, showing that the palming had not benefited him.

I told him to **stand and sway his body from side to side and to observe that the Snellen test card and other distant objects were moving opposite to the sway. While swinging with his right eye covered, he again read the 15-line and then the 10-line letters without any blurring.**

I then tested his vision at the near point with the fine print on the Fundamental card. At first, he held the card about six inches from his eyes, as I directed him, but drew his head back some distance as though he had been struck. This happens very often while testing a patient for the reading of fine print. I paid no attention to it, but directed the patient to hold the card twelve inches away instead. He was able to read Number 3, or the third sentence from the top of the card, which has good sized type. He said that the words were blurred. As he tried to read the fourth sentence on the card, his shoulders began to twitch again, as they did while he palmed, so I did not encourage him to go any further.

I saw from the beginning that I would have a problem to solve, so I decided to study his case until the next time I treated him. The directions I gave him for home practice were very simple. He was glad to know that what he was called upon to do by himself was simple; he was directed to **stand, with his feet one foot apart, and to sway his body with a long, slow, easy swing, not noticing anything that came in his line of vision.** He was told **not to worry about what line of letters he was able to read on the test card, but to be sure not to try to improve his vision by making any sort of an effort.**

He was to remember to glance only at the white spaces dividing each letter on the card and to place himself at least a foot further away from the card each day. Modern teachers state that it is alright to "flash" glance at the letters, shift easy, relaxed on the letters. No effort to see=clear vision. While walking in the street, he was to hold his chin up and look ahead instead of looking down at the pavement, which had been his habit for many years. He was to imagine in this way that he saw the pavement coming towards him as he walked. Automobiles and other vehicles which were not moving but were against the curb were to be imagined to be moving opposite as he looked to the right or left while walking.

Eight days later he came for a second treatment. I used a large card which he had not seen before and placed him eighteen feet away from it. As he swayed, shifting from the test card to a picture on the wall and then back again to the test card, he was able to tell me which way the inverted E's were pointing on the line, which is usually seen by the normal eye at ten feet. The letters were quite clear to him.

I find that with difficult cases it is good to introduce palming in some way or another. When this patient closed his eyes and placed his one hand or both hands over his eyes, the twitch was very noticeable. If I asked him a question while his eyes were covered, he stuttered even more than he did when he was staring at me. This surely was a problem for me to solve and I will say that I worried a great deal about him. I did not want to fail him as others had. The thing for me to do was to undo the harm that was done to him.

The sun was shining brightly in the window of my office, so I placed him in a comfortable chair and arranged his head so that the sun shone directly on his closed eyelids. The sun is much brighter in the West than it is here in the East and it also has a great deal of healing power. Of course, I expected that the sun would be a great factor in the cure of this patient. **I kept him in the sun fully a half hour and then when I placed him in the shade afterward, I told him still to keep his eyes closed for a little while.** I did this purposely to get him accustomed to the darkness as well as the bright light while his eyes were closed.

I placed myself in a chair directly opposite him and held the small test card, black with white letters, in my hand. Then I told him to **open his eyes and to read one letter at a time and immediately afterward to close his eyes to rest them.** While he did this, his shoulders were perfectly still and he mentioned each letter without dragging his words as he did before. He flashed the letters on the line which is marked 5 as I was sitting about five feet away from him. I considered that very good.

I told him to sit in the sun again and with his chin raised and eyes closed, he sat perfectly still for another ten minutes. After that he was able to read the line of letters of the small black card which is marked 4 and each letter was clear to him as he read, with his body perfectly still and relaxed.

Then I spoke to him about palming. I explained that it was not necessary for him to keep his hands over his eyes any length of time, but to try what I have called "instant palming." He was to hold his hand cupped about a foot away from his eyes and as he drew it toward his face he was to gradually close his eyes and keep them closed as the cupped hand touched his forehead. This worked splendidly. As he kept his hand over his eyes only for a part of a minute, he did not cause any strain as he did before, and he enjoyed doing this because as he explained it, he felt free from strain and tension. It was good to see the patient smile and to listen to his speech of gratitude which I enjoyed and understood very well.

After the treatment was over, I told him not to try palming at all by himself until I saw him again. Sun treatment was advised and he was to get as much of it as he possibly could, always allowing the sun to shine on his closed eyelids, which was best for him. He was told again to imagine stationary objects moving when he moved his body and to remember to blink frequently. I also explained to him that the thumb movement (see page 2 of this issue), which Dr Bates discovered some time ago, was a benefit in cases where it was difficult to have a patient relax while trying to improve his sight.

One week later he came again for another treatment. He had a tale of woe for me; the sun and substance of his failure in home treatment was that he tried too hard. To begin with, **he blinked too fast, which is as bad as not blinking at all. When patients acquire the habit of blinking too fast, they are very apt to stare while they blink.** Some of my work with him had to be done over again, because he had tried too hard by himself. He had forgotten something that I had asked him to do and that was to telephone me every day and let me know how he was getting along. It only takes a few minutes to write a short letter or go

Long Swing and Sway with Eyechart, using eye with less clear vision.

Swing or Sway with the eyepatch on the right eye and 'flash' 'shift for a fraction of a second' on a letter on the eyechart with the left, less clear vision eye without stopping the swing. Notice opposite movement of the chart.

to a telephone booth and explain the failures or the success in home practice. Because this patient failed to do as he was told, much of what I had already told him had to be repeated over and over.

This case proves again that all patients cannot be treated in a similar way. Each one has to have individual treatment.

I made the next treatment as simple as possible and he spent most of the hour shifting to the white spaces of the large test card and then to the white spaces of the small test card that he held in his hand. Shifting from the near point, where letters were easily seen, to the distant card, brought about a relaxed state of mind and body and we proceeded once more with other things which were to help him permanently. In order to avoid blinking too fast, I told him to again place his hand "cup fashion" about a foot from his eyes. This time he was not to touch his face with his hand but to draw the hand in as though he were going to touch his face. As the hand moved toward him, he was to close his eyelids gently and in this way as he again drew his hand away, he opened and closed his eyes, keeping time with the hand as he moved it backward and forwards. As the hand was drawn away from his face he opened his eyes easily and not too quickly.

**I had emphasized that he must not snap his eyes shut or open them too quickly.** He practiced this until he became tired, which was more than ten minutes each time and then he would sway as a diversion. This new way of teaching him to blink without blinking too fast helped him to keep his eyes open for part of a minute, while closing them took only part of a second. This helped him to blink one blink at a time instead of blinking rapidly, with a nervous twitch which caused more strain. In order to improve his vision and lessen his strain and tension, I had to give him treatment just opposite to the usual way in which patients are benefited.

He came again one week later for his last treatment, at which time he read the whole of the Fundamental card, reading Number 15, which is fine diamond type, at less than twelve inches, holding the card in the shade. In the sun he was able to read it at less than eight inches. He no longer dragged his words as he had in the beginning when I first treated him, and only at rare intervals did I notice his shoulders move with a twitch when he forgot to blink as he was talking to me.

On July 20, 1927, he came to me for his first treatment in a pathetic condition. On August 25th, about a month later, he was a different man entirely, having no more discomfort or pain in his eyes.

## Announcement

The editor has just received a circular letter from a correspondent in the West, who claims to have invented a new apparatus for improving the sight. I should like to caution readers of this magazine about this apparatus, because there have been others of a similar nature which were a disappointment.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MARCH, 1928

### First Visit Cures

The word "cures" is used advisedly. It is a fact that some people have been cured of myopia in one visit, after relaxation of the nerves of the eyes and other parts of the body was obtained.

Suppose the patient is near-sighted and can only see the big letter "C" at fifteen feet, a vision of 15/200. Let the patient walk up close to the card until he can read the bottom line. The distance may be three feet, five feet or farther. The first letter on the bottom line may be the letter "F." With the eyes open, it is possible for the patient to imagine the letter "F" quite perfectly, but with the eyes closed, he is more easily able to remember and imagine he sees the letter "F" much better.

Palming is a great help when remembering or imagining the letter "F" with the eyes closed. **By alternately imagining the letter "F" with the eyes open, and remembering or imagining it better with the eyes closed, the memory, the imagination and finally the vision for the letter "F" is very much improved.**

If the patient becomes able to see the letter "F" at three feet, or to imagine he sees it quite perfectly, he should be encouraged to walk back and increase the distance between the eyes and the letter "F" about one foot. When the patient becomes able to imagine the letter "F" at four feet, he should go back another foot, alternately imagining it with his eyes open and remembering it much better with his eyes closed. By gradually increasing the distance of the eyes from the letter "F," all patients who practiced this method obtained normal vision temporarily at the first visit.

The length of time required to obtain a permanent cure is variable. Some patients with not more than one or two diopters of myopia may require many weeks or months of daily treatment before they are permanently cured, while others with a higher degree of myopia sometimes obtain a cure in a much shorter time.

## The Period

By W. H. Bates, M.D.

Of all the methods employed in obtaining normal vision, the memory and the imagination of the small black, white or any color period is among the best. The period may be an optimum for some persons who can obtain relaxation with its aid after other methods fail.

When the period is seen perfectly, it is not stationary but moves in various directions with a slow, short, easy swing. It is a fundamental fact that a period is seen best when it appears to move a distance of about its own diameter. When the period has a slow, short, easy swing, the eye is at rest and when it is at rest it is always moving to prevent concentration, trying to see and other efforts to improve the vision. The eyes shift point to point (small part to small part) on the period, causing it to show oppositional movement.

It has been demonstrated that when the vision is good, any effort, no matter how slight, always impairs or lowers it. When this truth is demonstrated, it follows that normal vision cannot be obtained when an effort is employed. When a period is seen, remembered or imagined perfectly, central fixation is manifest or the period is not seen in all parts equally well. When the eyes of the patient move a short distance to the right of the period, the period should appear to the left of where he is looking. When he looks to the left of a period, it should appear to be to the right of where he is looking, and the left side of the period is seen best while all other parts are seen worse.

Many patients complain that they find it difficult or impossible to remember a mental picture of a period. They say that the period is blurred or indistinguishable. To them the larger letters are apparently clearer than small print or a period. It is difficult to make some patients understand that the large letters may have blurred outlines of a fraction of an inch or more, if an effort is made, and the letter may still be distinguishable, whereas any effort to remember the period perfectly will cause a blur which is sufficient to make the small period indistinguishable. With perfect sight, no blur is seen, and the eyes are at rest.

When a patient has perfect sight, it is usually continuous. One may see a large letter quite perfectly and by covering over one half of it, the uncovered half is just as black as the whole and may be remembered, imagined or seen as black as the whole letter. Then if a small area is blocked off, with the help of a screen, one quarter, one eighth, one tenth-any part in fact-is just as black as the entire letter.

If the patient holds his forefinger six inches in front of his face and moves his head and eyes from side go side, it is possible, without looking at the finger, to easily imagine that the finger is moving in the opposite direction to the movement of the head and eyes. This is called the **variable swing**, because the amplitude of the swing varies within wide limits. At six inches from the face, the amplitude may be three or four inches, while a similar object held at five feet or further will have a very short swing-so short that it is not always apparent. A small period, likewise, at six inches may appear to move within an amplitude of several inches, while at ten feet it may appear to move less than one half of its diameter. At times, the movement may be so short that it cannot be distinguished at ten feet, although it is present. Since a **short swing improves the vision more than a long swing, the benefit of the short swing of the period at the distance is manifest.**

The vision of a perfectly black period may be used to improve the vision of large letters or other objects. By practice, one becomes able to remember or imagine a perfect period at all times and in all places when desired. An imaginary period, when placed on the top or some other part of a large letter, improves the vision of the letter. Imagine a black letter is composed of hundreds of small black periods. Shift continually, easy from one period to another. Use central fixation - see one period (small part, tiny point) at a time darkest black and clearest in the center of the visual field and shift/move the center of the visual field from period to period (point to point).

The memory of a perfect period is a benefit to other conditions than the sight. When the eyes are tired, the perfect memory of a period at once brings a feeling of perfect rest. **Symptoms of various diseases of the eye have been relieved at once by the memory of a perfect period.**

It has been published more or less frequently that the memory of a period brings quick relief to pain. A man may have a broken arm which is ordinarily very painful, but the perfect memory of a period always relieves the pain, so that he is not conscious of the broken arm. One may suffer considerable discomfort or pain in a dentist's chair. The memory of a perfect period brings instant relief. It is impossible for a patient to suffer pain while his teeth are being treated, provided he is able, in spite of his surroundings, to remember a perfectly black period. A severe cough is usually relieved very promptly by the memory of a perfectly black period after other methods have failed.

There are many diseases which cause a great deal of suffering in which the memory of a perfectly black period has brought relief. A most interesting case was that of a nervous woman who complained that she suffered from a variety of symptoms. She could not imagine the cause which produced the symptoms of her trouble.

She said to me: "Doctor, I am a great sufferer with pain, fever, loss of appetite and from one thing in particular which I am unable to describe."

I remonstrated with her and said: "How can you expect me to treat you unless I know what is the matter with you?"

She answered: "That is what many other doctors tell me."

This case interested me very much and I said to her: "Your unknown disease is causing you much suffering, but I can promise you complete relief, provided you are able to remember a period which is perfectly black."

She said that she didn't think that she could do so because her memory was not good, and so I spent a great deal of time with her trying to improve her memory and imagination of black, white, blue and other colors. I had her look at a black letter and imagine one part best and the rest of the letter worse.

Under my instruction she became able to see quite perfectly a letter "O" which was about one quarter of an inch in diameter, and to see it quite perfectly if it were near enough to her eyes. With the aid of a screen, she became able to see one half of the "O" as well as the whole of it. By further use of the screen, the part of the "O" which she saw best became very small, until it was reduced to the size of a small period. This seemed to help.

Then I gave her a rubber ball and told her to go down to the seashore, near which she lived, when the tide was going out, throw the ball in the water and watch it recede from the shore. She was also directed to note that the ball appeared smaller as it gradually

Shift point to point on a small black (or any color) period and remember, imagine and see it clear, moving. Do this with the eyes open, and in the imagination with eyes closed.  
Think of the period any time during the day to relax, clear the mind, relax the eyes, activate eye shifting and clear vision.

Variable Swing  
Finger in front of the face, move the head side to side and see the finger move in the opposite direction.

floated out to sea.

When the relief came, she at once telegraphed the glad tidings to me. At once I telegraphed back to her to practice with a rubber ball in the same way each day until her memory of the ball floating out to sea and appearing to be the size of a small black period was perfect. After her memory of the rubber ball becoming the size of a period became perfect, she found that she could obtain a mental picture of the small black period without using a rubber ball. She believed that she had been cured of her unknown malady.

#### Opera Singers Voice Cured by Dr. Bates

About twenty years ago I had been walking through Central Park and decided to sit down on a bench to rest. A well dressed man and woman came along and sat down on the same bench. The woman was very much excited and talked very rapidly in Italian to the man. Finally the man turned to me and said:

"Do you know Dr. Bates? We are looking for his office, because it is very important that my brother sing tonight in the opera. My brother's voice failed and we at once consulted a doctor on the throat who said that my brother's throat was paralyzed and that nothing could be done. We have just heard that Dr. Bates helped another opera singer by giving him instant relief after his voice had failed."

I asked the man where his brother was. He replied that he was at his hotel. I then confessed to him that I was Dr. Bates and said that I would be very glad to help his brother. I told him that I was well acquainted with the people at the opera house, having been the attending physician there for several years and that they would vouch for me.

The man at once called a cab. I asked him if he were going to the opera house first, but he replied that it was not necessary, that he believed that I was Dr. Bates. When we reached the hotel, we went to the singer's room at once. The man spoke a few words in Italian to the singer who was lying on a bed. He smiled and opened his mouth wide so that I could see his throat, which seemed to be very large. I requested the man to tell him that it was not necessary for him to keep his mouth open.

There was a piano in the room with a great deal of music lying around. I had the patient sit down at the piano while I examined some of the music. One sheet that I picked up was full of complicated music. I asked the lady to let me have her breast pin for a moment and with the aid of the pointed pin, I touched a small black dot which came after one of the notes. Then I turned to the man and asked him to have the singer sing that note.

The singer looked at the note and laughed. I walked up to him and pounded him on the back and said with a laugh: "It's funny, isn't it?" He replied: "Yes, it's very funny." I said, "Sing it."

He did sing it. They were all very much overcome and could not express their gratitude enough. They thought that it was the blow on the back which I had given the singer which had restored his voice, or that my finger had a magic touch when I pointed out that particular note of music. They did not know, and I never told them, that he was suffering from **paralysis of one or both vocal cords due to mental strain**. When he looked at the music and saw the little black dot perfectly black, his mental strain was relieved and his voice came back.

Shift on the tiny  
black dot to  
relax the mind.

## The Story Of Jacqueline Sherman and How She Was Benefited

By Emily C. Lierman

The story of Jacqueline and how she was benefited in a very short time is well worth writing about. She came to me with her mother in January, 1927, at the age of seven, and was recommended by a **colonel of the United States Army**. After he had cured himself of presbyopia and pain caused by eyestrain, he sent many patients to Dr. Bates and to me.

Because of the great distance from Dr. Bates' office, the Colonel was unable to visit the Doctor personally and therefore obtained his knowledge of the method from the Doctor's book. Being an Army officer, it was necessary for him to have good sight and as glasses were objectionable to him, he had to do something to improve his defective vision. After practicing the methods described in "Perfect Sight Without Glasses," he became able to read book type and also newspaper type without the use of glasses, and then he began to boast about it. Jacqueline's father, also an Army officer, became interested in the Bates Method through him.

Jacqueline was wearing very heavy glasses, which she had worn for more than six months. She had difficulty to keep from staring or squinting through them in order to see any distance at all. At fifteen feet, her vision was 15/30 with glasses, proving that glasses did not improve her sight very much, if at all. Without them, her vision with the right eye was 15/200 blurred, and with the left eye 15/50 blurred.

Although she read up to the 50 line with her left eye, while her right eye was covered, she strained hard to read and twisted her head from left to right in such a way that her mother called her attention to it and asked her to keep her head still, if possible. I was glad to have her mother present, in order to see this, because I felt that she would be of help to Jacqueline in her treatment at home. Her mother told me that she saw the child but once a week, as she attended a school some distance from her home. For this reason, she needed her mother's encouragement as well as mine to practice enough to keep up her interest in the method for bettering her eyesight after she had left my office.

Jacqueline had a wonderful memory and it was not hard for me to help her while her eyes were closed, which I had her do, after the test. She palmed for more than five minutes while I was talking to her mother, and as I noticed her becoming uneasy or restless, I encouraged her to keep her eyes closed and covered while I asked her a few questions. I asked her if she could imagine that she was writing her name with pen and ink on a sheet of white paper. She said she could do that quite easily. I directed her to spell her whole name and then imagine each letter, and to place an imaginary period at the end of her name. I asked her next to forget about her name and remember the period, which she was able to do, and then she remarked, "The period seems to move, it doesn't stand still." Immediately after that I told her to open her eyes and to read the card with each eye separately. Her vision in that short time improved to 15/30 and she remarked how clear the letters were.

She was asked to palm again and to describe things which she had seen while her eyes were closed. She told me the different colors of dresses which she had worn recently, and she very readily described each one in detail. This time she palmed for about ten minutes or longer and when she again read the card, her vision with each eye separately had improved to 15/10. Her mother and I noticed that the squinting had stopped and that her eyes were open in a natural way. I gave her test cards and other material

necessary for her to practice with and explained to the mother that it was necessary for her to supervise the practice at school and at home if the child wished to be relieved of her eyestrain.

Jacqueline could not come to see me for some time after that and it was on July 19th of the same year that I saw her again. She had a great deal to tell me and it was good to listen to her explain how the one treatment I had given her had benefited her sufficiently to forget that she had ever put on glasses. It was only when she became excited while explaining things or telling something of great interest to her that she forgot to blink. Then something happened which frightened the mother but which caused me no concern whatever, because this happens very often to children. When she was excited or talked fast and forgot to blink, the pupils of both eyes became very large. This, however, had no effect upon her vision whatever, as her mother soon found out.

I asked the child if she had been faithful in the directions I had given her, which included the reading of microscopic print which is much finer than diamond type. She immediately produced some of the fine type I had given her at her first visit and placed herself by a window with her back to the sun. In this way the sun shone directly on the card and she read the fine type without any effort at six inches. She said that she never forgot to practice with fine print almost every day since I had seen her.

I then placed an unfamiliar test card fifteen feet from where she was sitting and asked her to read the card for me. She read every letter on that card with each eye separately and without squinting or straining. Her mother wanted to be sure that her vision for further distances had improved so I placed her by my window and told her to look off at a distance at a sign which was about 400 feet away. From the window, the letters on this sign seemed to be about the same size as the letters on the last line of the card she had just read. She held the card with microscopic type in her hand, and as she shifted from the white spaces of this type, holding it close to her eyes, to the distant sign, she read every word of the sign without a mistake. Her mother exclaimed that such a thing would have been impossible before she had had her first treatment.

We chose another sign at less than 400 feet away. To prove to her mother and to Jacqueline herself that staring and straining always lowered the vision, I told her to stop blinking for a fraction of a second and to look at the print instead of the white spaces and then to look off at the distant sign we had picked out for her to read. She immediately turned away with a strained expression on her face, and with a great deal of squinting. She objected strongly to doing the wrong thing, as she explained it. (Shift on the print when looking at it and strain is avoided.)

I gave her a little sun treatment with her eyes closed, using my sun glass steadily for about five minutes. I next directed her again to shift from the white spaces of the nearby fine type to this sign less than 400 feet away, and to frequently shift from the near-by white spaces to the spaces between the letters of the sign; she read every part of the sign perfectly. Modern teachers state to look directly at, shift on the print - shifting and central fixation. Look at the white spaces to relax the eyes, mind when not reading the print.

It does not require a great deal of intelligence to do what Jacqueline did, nor does it mean that the patient has to be young to accomplish as much as she did. She merely followed my directions and asked no questions as to whether the vision would continue to improve. She accepted everything I said or directed her to do as a positive means of benefiting her sight. Her mother's silence during the treatment helped me greatly in benefiting the child. It so often happens during a treatment that the parent or guardian will interfere or ask questions regarding the progress that the child is making, and this, of course, does not help the child nor me.

At the time I was treating Jacqueline, I also had a boy under treatment for myopia. He was twelve years of age, almost twice as old as the little girl. Every time the boy came, his mother worried me all through the hour of treatment and because of the mother's interference it took me twice the length of time to cure him. I am not speaking against this mother; I am only stating a fact. Both mothers were equally fond of their children, but mothers often make the mistake of fussing when it is quite unnecessary.

Jacqueline was again brought to me by her mother four days later as a sort of a checkup. I repeated to her over and over again that staring lowered the vision and that blinking always improved her ability to see without out tension or strain. Every card that I had for testing was used, so that her mother could see for herself that her child had really improved. She did well with the memory of the period whenever it was introduced during each treatment, so I decided that it would be a good plan to teach her mother how to apply the treatment at any time in the future when it seemed necessary.

The mother was directed to tell her to palm and imagine that a sheet of white writing paper was placed in her lap; then to imagine that she was making a small black period, just large enough so that she could imagine it as a small black spot. She did this without any difficulty. Her mother reminded her that she must imagine that the period was moving, so we spoke of **the pendulum of a large clock, which moves slowly from side to side, and I instructed the child to imagine that her body was moving just that way.** She kept up this movement as she sat perfectly relaxed in her chair and then she was asked to imagine that the period was moving opposite to the movement of her body. Jacqueline enjoyed this very much.

Before she opened her eyes, I placed myself six feet away from her and held in my hand the small Fundamentals test card with the inverted "E's." The bottom line of this card is seen with the normal eye at two feet. In the presence of the mother who wanted to be doubly sure that her child was not memorizing instead of actually reading, I placed this small card upside down. In this way, the letters pointed directly opposite from the way in which they point when right side up.

When the girl opened her eyes after the period practice, she said that the "E's" looked perfectly clear to her up to the fourth from the top line, which, of course, would be the fourth from the bottom line when the card was right side up. She could see the separation between each letter "E" on the other lines but not very clearly. Purposely, I had my hand over the three upper lines, but suddenly I removed my hand. Jacqueline leaned forward in her chair unconsciously, and as she did so, she began to squint her eyes. Her mother checked her before I had a chance to do so, which pleased me.

She closed her eyes for an instant, remembering the swinging period and then opened her eyes and looked toward the card held in my hand. Immediately she exclaimed: "If I remember the swinging period as I look at the card, I can imagine that the first letter 'E' on the bottom line is turned the right way." Her mother came close to the card to see whether the child had made a mistake; she had not. Her mother asked if it were possible that the child could see so small a letter at such a distance when less than a year ago, she had been so terribly myopic. By alternately closing her eyes and opening them, looking at the white spaces between each letter "E," she could tell in which direction each letter on the top line was pointing. When she closed her eyes for a fraction of a second, she had relaxed enough with the memory of the moving period to see each letter "E" perfectly without tension or strain. Look directly at the E, shift on it part to part, blink, relax and the E will be seen clear.

Objects that swing side to side (and in other directions) such as the pendulum in a grandfather clock... relax the mind, eyes, keeps the eyes in natural shifting movement and vision clear. Place interesting, colorful g adgets that contain movement in the home. A globe with colored moving sparkles, colored water fall, pictures with shiny colored sparkles that flash as the eyes move across the picture, toy train set, hanging objects that move about in various directions...

At her last visit to me the final test was made. This was on August 1, 1927. As I stood ten feet away from her, I held in my hand a popular magazine with ordinary sized type. She did not know the name of the magazine, nor did she have any idea of what I was going to do. I was standing in a good light and her mother was sitting where she could watch us both. I placed my finger at the beginning of a sentence at the top of a certain page. I told her to watch my finger as I passed it below the sentence and told her not to pay any attention to my finger, but to see the thin white line which separated this sentence from the one below. This was done in a flash and then she closed her eyes again.

I asked her to imagine what the second word of that sentence might be. While her eyes were still closed, she said that it appeared to be a word with three letters and that the first letter appeared to be straight. She said that she could imagine that the word might be "was," which was correct. Her mother said that it was almost impossible for her to see that word so far away, but when she again mentioned words correctly as I passed my finger along the page of that magazine, her mother was convinced that Jacqueline's vision had really improved to more than normal average vision.

Jacqueline was what I call an unusual case, but I feel that any child of her age can do as much if not more than she did. This case recalled to my mind something which I had heard Dr. Bates say many times: "There is no limit to vision."

## Case Report

**Editor's Note:** We believe that the following letter recently received by Mrs. Lierman will interest our readers. It is from W. B. MacCracken, M.D., Berkeley Bank Building, Berkeley, Calif., who has been very successful in applying the Bates Method to his patients. We would recommend him to anyone living in his vicinity who desires treatment by this method.

February 24, 1928.

Dear Ms. Lierman:

Perhaps you have once or twice wondered why I have not written you anything about the Bates work that I am doing here. I trust you have. There are several reasons why so many long weeks have elapsed and I have not made any report. Tonight I am going to have a little talk with you. And I feel sure I will get to the ear of Doctor Bates himself through you.

First, to put it briefly, I can do some of this work very well. I know this because I have had some very fine success. The reverse side is that nobody wants to have their eyes cured this way. This does not mean that I am discouraged in the least. The ripples are getting a little larger. Last Monday night I had four beginners—two who were about to put on glasses, and two who have worn them for several years. (The following sentence may or may not be a misprint. It is printed here exactly as in the original magazine.) I started them all with a twenty minute talk, and if twenty-five per cent last to the tape I will not feel ugly. It is very encouraging to see evidence accumulating to prove that this little small whisper is beginning to be heard in the din of this wilderness of eyesight moderns.

Referring to the case of little Edith—. She was a very sweet little girl, but at ten years, after eight years of effort and failure, she hated the thought of eye work, and her parents were likewise tired on the last lap. They were very good, but had not the least control over her. When a child tells you that she is determined not to learn how to swim, and then refuses to go through the motions — well, at the end of three months' work, I had won her confidence and was just beginning to get results, and right there they decided not to give me another month, even though I insisted it was to be free of any charge. I had charged \$50.00 a month, and saw her at the house six times a week, although it took me an hour to drive there and back. They paid me \$150.00, and one Sunday morning three drunken Mexicans smashed my car on the way there; it cost me \$240.00, and they didn't have two hundred and forty cents. "Sacrifice is the law of progress." The girl's parents and I parted the very best of friends. I even hope that someday I will feel competent to take up that case again, when she is a little older.

On January 9th, a Mr. S. came to me, 66 years old, with a cataract in each eye. One had been operated on several months before, and that eye was distinctly worse. He had spent \$300.00 in two years. His last experience was \$47.00 for a pair of glasses that were useless. He came on Monday morning, and could not read his watch without glasses, nor see the "C" of the small card, and on Saturday morning of that week he read the bottom line of Fundamentals — so much was his "vision benefited" in one week. In one month he had read in one day, without glasses, five pages of the Sunday newspaper, and another day twenty-one pages of a book, and could read big signs two hundred feet away. At the house of a patient of mine he read half a column of a newspaper.

A few days after that, he simply broke an appointment and went off and bought another pair of glasses. A Mrs. Chandler, an old graduate nurse, who is helping me with this work found out from his wife that he decided it would take too long by this method to see without glasses. I believe he got into a mental complex, the crisis of his last few years of misery, and could not realize that another four weeks would probably have had him back at work. Of course, glasses cannot help him, and I will not be surprised if I hear some of these days that I ruined the poor man's eyes, and that is the reason the new glasses won't work.

On Saturday last, a Mrs. Kinley came ten miles to me. **She is eighty-four and has a cataract in each eye.** When I took her glasses off, she could not walk around freely, and could not read the "C." In a little while, she read four lines. **Palming and the sun glass.** On Thursday, five days later, she came again on the trolley, and reported that she had not put her glasses on since I placed them in her bag myself, and that she had done all her housework and her marketing and her sight was very much improved. She is a keen, strong woman at eighty-four, and I am hopeful that her earnestness and courage are going to make a better ending than I had with Mr. S. who was only 66.

You once suggested that I get some clinical work. This was actually promised me, in the City Clinic.

I am always mentioning the work to my patients and my friends, and I am more determined than ever to go to New York for a proper training as soon as it is possible. In the meantime, I am learning much here alone, and I trust that Doctor Bates and you yourself will not lose patience with me or my work. Sometimes I feel like the man in the middle of the stream getting things thrown at him from both sides, but as nothing is hitting me, I am really getting some relish out of that side of it, too.

You may be very sure that I will be more than pleased to hear from you at any time, and I hope that when I write again it will be to tell you that I can set the date when I can start for New York.

With kindest personal regards for Doctor Bates, as well as for yourself. Yours most sincerely,

W. B. MacCracken, M.D.

Dr. MacCracken was instructed, certified in the Bates Method by Dr. Bates, cured many patients' eye problems and wrote two books on Natural Eyesight Improvement; Use your own eyes and Normal Sight Without Glasses. Free at: [www.clearsightinfo.com](http://www.clearsightinfo.com) and in the Book; Do It Yourself - Natural Eyesight Improvement - Original and Modern Bates Method.

### Brain Tension

Tension, Strain, Relaxation  
Nerves, Cells in Brain, Body, Eyes, Retina

The brain has many nerves. Part of these nerves are called ganglion cells and originate in some particular part of the brain. Each has a function of its own. They are connected with other ganglion cells and with the aid of nerve fibers are connected with others located in various parts of the brain as well as in the spinal cord, the eye, the ear, the nerves of smell, taste, and the nerves of touch. The function of each ganglion cell of the brain is different from that of all others. When the ganglion cells are healthy, they function in a normal manner.

**The retina of the eye contains numerous ganglion cells which regulate special things such as normal vision, normal memory, normal imagination and they do this with a control more or less accurate of other ganglion cells of the whole body.**

**The retina has a similar structure to parts of the brain.** It is connected to the brain by the optic nerve. The eyes are an extension of the brain.

Many nerves from the ganglion cells of the retina carry conscious and unconscious control of other ganglion cells which are connected to other parts of the body. The state of the eyes affects the body and the state of the body affects the eyes.

When the ganglion cells are diseased or at fault, the functions of all parts of the body are not normally maintained. In all cases of imperfect sight, it has been repeatedly demonstrated that the ganglion cells and nerves of the brain are under a strain. When this strain is corrected by treatment, the functions of the ganglion and other cells become normal. The importance of the mental treatment cannot be over-estimated. Relaxation of mind, body, eyes = healthy eyes, nerves, cells, clear vision.

A study of the facts has demonstrated that a disease of some ganglion in any part of the body occurs in a similar ganglion in the brain.

Brain tension of one or more nerves always means disease of these nerve ganglia. Treatment of the mind with the aid of the sight, memory and imagination has cured many cases of imperfect sight without other treatment.

## Cataract

By W. H. Bates, M.D.

Some years ago a professor of anatomy was exhibiting the effect of pressure on the enucleated eyeballs of a dead cow and some other animals. At a distance of about twenty feet from the eye, the audience observed that the pupil was perfectly clear. Immediately after the eyeball was squeezed by the fingers of the professor, the area of the pupil became at once completely opaque, from the production of a cataract. Then when the pressure on the eyeball was lessened, the cataract at once disappeared and the eyeball became normal. Again squeezing the eyeball, a cataract was produced as before. And again, the cataract disappeared when the pressure was lessened. The experiment was repeated a number of times with the result that the pressure on the eyeball always produced a cataract, which was relieved by reducing the pressure.

There are two oblique and four straight or recti muscles on the outside of the eyeball.

The superior and inferior oblique pressing on the eyeball at the same time have always been followed by lengthening of the eyeball. The four straight muscles on the outside of the eyeball shorten the globe or eyeball by their contraction. In animals the eyeball has been shortened experimentally by operations on each of the four straight muscles, which increased the pressure temporarily. These operations were performed after death. Similar operations on the two oblique muscles at the same time produced pressure and increased hardness of the eyeball with cataract following.

**Patients suffering from cataract have increased the hardness of the eyeball, at the same time increasing the density of the cataract. While the cataract is being observed with the aid of the ophthalmoscope, it can be seen to change in size or density when the patient consciously or voluntarily increases or diminishes the hardness of the eyeball with the aid of the memory or the imagination.**

When a word, a letter, part of a letter, or other object is remembered perfectly with the eyes closed or open, the cataract can be seen by the observer to become less. But if memory of letters, colors or other objects is imperfect, the cataract always is seen by the observer to become worse. A great many cases of senile and other forms of cataract have been temporarily improved and this improvement has become more complete and more permanent by the practice of a perfect memory.

A perfect memory usually becomes manifest when the patient practices the optical swing. However, the cataract always becomes worse when the optical swing or the perfect memory is not practiced. To keep the eyeball hard by practicing an imperfect memory is difficult and requires effort. The practice of an imperfect memory is tiresome and requires constant attention of the patient. In

others it can be demonstrated that the formation of cataract in elderly people requires hard work and is exceedingly difficult. (Some of) these patients are difficult to treat because they cannot control the functions of the mind. (The function of the mind can be improved at any age, along with the vision. Improving vision improves function of the mind. Improving the mind, improves the vision. Stay active; mentally and physically. See left and right brain hemisphere activation, integration exercises.)

A perfect memory is easy. It is quick, continuous and beneficial. Patients with a perfect memory have consciously or unconsciously a perfect optical swing. They are able to remember, to imagine letters, colors and other objects continuously without any strain or fatigue. These cases are favorable and recover from cataract after they demonstrate that a perfect memory is beneficial.

The study of **cataract** has occupied the attention of eye doctors for many hundreds of years. **It occurs very frequently in India, China, Japan** and among people of the highest intelligence, as well as among those whose intelligence is of the lowest order. Some cases appear without apparent cause. It may increase rapidly or slowly and continuously, until the vision is completely lost.

Of all organic diseases of the eye which have received medical attention, measures of relief by operation or by the use of eyedrops have usually, in a large number of cases, been unsatisfactory. Cases have been operated upon in which a temporary cure was obtained. However, in too many of these cases the good vision obtained soon after the operation did not remain good. In some of these cases and without apparent cause, inflammation of the interior parts of the eye developed and was followed by serious loss of vision.

Some cases of cataract are found in the eyes of children soon after birth, sometimes in one eye, less frequently in both. The cataract which occurs in children is softer than in the eyes of adults and is more readily benefited by operation than in the eyes of adults. In some cases of cataract in children, the front part of the lens becomes opaque. Such a cataract is called an anterior polar cataract. Often, after the lens has been punctured, it becomes absorbed and good vision is obtained. In other cases an opacity forms on the back part of the lens which increases until the lens becomes entirely opaque. Here again repeated puncturing of the lens is followed by a total opacity of the lens, and its complete absorption. In a third variety of cataract in children, an opacity of the lens forms in one or more layers of the lens, which is usually absorbed after repeated punctures of the lens are made with a sharp needle. This operation has been called "needling of the lens."

Birth trauma, forceps used on the baby's head, neck, suction delivery, falls, head, neck injury can misalign the neck vertebrae, bones of the skull, eye socket (where the eye muscles are attached, nerves, blood vessels pass through and the eyes rest), resulting in: pressure, tension on/in the eye, lens, retina, eye muscles, abnormal eye muscle/eye function, movement, abnormal eye shape, incorrect focus of light rays, pressure, tension on the nerves, blood, lymph vessels in the neck, head, eye muscles, eyes, retina causing unclear vision, cataracts, astigmatism, crossed, wandering eyes and other abnormal conditions. Chiropractic and Cranial Sacral treatment to align the neck vertebrae and bones of the skull/eye socket and the Bates Method removes the pressure, tension from the eyes, lens, retina, muscles, nerves... the eye returns to normal health, shape, function - cataract and other eye problems are reversed, cured without surgery, vision is clear.

When cataract occurs in adults of forty years or older it is called senile cataract. In adults, the operation of needling the lens is not so successful in being followed by absorption of the lens. In some cases, if not in a large number, better results are obtained by removing the whole lens by one or more operations. There are many diseases of the eyes such as inflammations of the iris and choroid which are believed to produce cataract. The removal of the lens is usually very difficult without injuring the iris, choroid and retina.

In cataract the crystalline lens becomes opaque and being opaque it interferes very seriously with the vision. To obtain good vision, eye doctors were usually able to improve the sight by the removal of the opaque lens. After the lens was removed, the vision was materially improved by the use of strong glasses, which rarely improved the sight to normal.

**I have studied the physiology of the eye and I have repeatedly published the fact that it is much better to cure the opacity of the lens so that the patient could have normal vision with a normal eye rather than to relieve the blindness by the removal of the lens.** Curing rheumatism of the hand by an operation which removes the hand is not the best treatment. Likewise rheumatism of the big toe is not considered a proper case for amputation. Medical or simple treatment without an operation will usually result in a cure.

I do believe in operations when necessary or where medical treatment fails to correct the trouble. However, removing the lens from the eye does not cure cataract of the lens nor does it prevent cataract from forming in the other eye.

Since cataract or opacity of the lens is caused by tension, relaxation should cure or prevent the trouble. If relaxation fails to cure cataract we should consider this fact an evidence that tension is not the cause of cataract. Relaxation can be obtained with the aid of memory, imagination and sight. If the eye of a child is injured by a blow and a cataract forms early or late in life it has always been demonstrated that the eye with cataract is under a tension.

Treatment which brings about relaxation always cures the cataract after a considerable amount of treatment which may require several months or longer. Among the many methods of treatment, the amount of **relaxation necessary** to be followed by a cure is a **perfect memory, perfect imagination** and the benefit obtained by **sun treatment**. **Central fixation** has in some cases cured all forms of cataract - senile cataract, soft cataract in children, **cataract caused by sugar in the blood and other poisons.**

It is found that when patients sit **facing the sun with both eyes closed and move the head a short distance from side to side**, they can stand the strong light of the sun for longer periods of time than they can with the eyes open. When the sun is not shining, a strong electric light is a good substitute.

Much quicker improvement in the sight can be obtained with the proper use of the **sunglass**. The patient is directed to look down while facing the sun and to do this continuously without effort or strain. The operator lifts the upper lid with the thumb of one hand. When the white part or sclera of the eyeball is exposed to view he quickly concentrates or focuses the strong light of the sun on the sclera, moving it continuously and only for an instant at a time.

## A Case Of Cataract

By Emily C. Lierman

There was a time when I thought that all cases of cataract could be treated and benefited by one and the same method. I know now that this cannot be done for many reasons. Age has nothing to do with treatment for the cure of cataract, because I have had patients over eighty years of age who responded much quicker and became well much sooner than younger patients who were troubled the same way.

I was treating a woman with cataract who was seventy-seven years old, at the same time that I was treating another woman, age sixty-two. Both women had the same amount of vision with the test card, and neither one could read newspaper or book type. Yet, the elder of the two was benefited and the cataract of both eyes had entirely disappeared, while I was still working hard with the younger patient who was becoming irritable, rebellious and most discouraged, because of the increased length of time required to benefit her.

Neither of us was at fault as far as my good judgment goes, because she was faithful in what I directed her to do when I was not with her. While I was treating her, I had to remember constantly that there was a man named Job who was severely tried, according to the Old Testament of the Bible. However, my dear patient did not know of my endurance because I kept smiling always. She was very nervous and had cause to be. Money was no object to her but a great disappointment had come into her life. So great was it in fact, that all who knew her thought she was losing her mind. For this reason, my heart went out to this patient who suffered mentally because of her wayward son. Extreme mental, emotional strain=strain, tension in the body, mind, eye muscles, eyes=cataract, unclear vision.

During the hour, or I should say two hours of her treatment, because I could never accomplish anything much in less time, she would mention the name of her boy who, although he was of age and married, was still her little boy. Her room, which was cheerful and sunny, had pictures of him all over the walls. Some of them were baby pictures and there were others taken at the ages of sixteen and twenty-one and when he graduated from college. I noticed particularly that when she looked at his baby pictures her face would show signs of tenderness and relaxation. But when she looked at the pictures of his later years she would close her eyes and her face would become wrinkled with age and tension.

For days after I had noticed this, I studied her case and planned a different way of treating her. All my spare moments were spent in thinking out the best way to relieve her strain which prevented a permanent benefit.

Weeks grew into months before I finally conquered the wrong, or really helped her to overcome her disappointment and nervousness. **In seven months' time with treatment several times every week, never less than three treatments each week, she finally became able to read every test card, even to the ten line letters, at fifteen feet.**

She had been a great reader, and could read a whole book in less than two hours when she was much younger. Therefore it was a terrible disappointment to her when her sight failed and she had to forego that pleasure. Occasionally, a neighbor or a friend would visit her and read her favorite books aloud to her. Now at the end of seven months' treatment of her eyes she was convinced that I had told her the truth; that she would become able to read again without the aid of glasses.

Neighbors and friends were invited to call so that they could see with their own eyes what she was able to do. These friends knew how she had doubted me. They doubted me too, except one who was at one time a patient of Dr. Bates. This friend had not called because she was too far away, but she had written to my patient. What she wrote gave my patient enough faith and confidence in me to start the treatment, although she doubted me. She told me so in plain English. She was not the only patient who doubted me at the beginning of the treatment and who later on believed in me completely.

When the vision of this patient became normal for distant sight, she soon was able to read the finest print readily without glasses. I had not tested her ability to read fine print because I feared the bad effect of disappointment if she failed to read it. My experience with other and similar patients encouraged me to believe that if I could improve her distant vision to the normal that she would soon become able to read the fine print, "diamond type," without the aid of glasses.

I felt that it was useless for me to test her ability to read fine print from our usual test cards, so I asked her if she had some book in her possession containing small print, and she answered me by pointing to a large dictionary fastened to a stand in a sunny corner of her room.

Before I asked her to go near the dictionary, I said, "I have had patients with your trouble who became able to read the small print of the dictionary by placing a small card with much finer print in the neighborhood of the small letters of the dictionary." As I watched her closely while saying this and noticed her frown, I said quickly, "Of course, I do not expect you to do this just now."

This remark worked something like a magnet, for she at once hurried to the dictionary and with the aid of the small card which she received from me and which contained fine print or diamond type, she read occasional words of the dictionary, much to her delight.

There were times during the months which followed, when she had relapses which caused depression, but after she had removed some of the pictures of her son from the walls of her room, the conversation while I was with her was more about herself and the improvement in her eyes. In the beginning, her distant vision with the test card was 10/30 with the right eye and 10/50 with the left. At the end of her treatment her sight was better in each eye than the average normal eye.

During the last treatment, I spent the day with her, and she read for me a large part of a book in which the print was very small. She announced with a great deal of pleasure that for years she had been unable to read this book, with or without her glasses. The cataract in both eyes was very materially improved. Only the lower inner part of the pupil had a trace of the cataract in each eye.

The principal part of the treatment given this woman was the sun treatment. While I was with her, I applied the sun glass. When I was not with her she was able to use the sun glass with benefit or just the same as I used it. Because she was of a nervous temperament, I always **focused the sunlight on the outside of her closed eyelids.**

## Questions And Answers

Q - Is it all right to palm while lying down? Is it better to sit or stand while doing so? If the arms get tired is it all right to rest the elbows on a desk or something like that while palming? Or is it best to hold the elbows up free from all support?

A - It is all right to palm while lying down. Palming should not be done while one is standing. The elbows should rest on a desk or table or on a cushion placed in the lap. One should be in as comfortable a position as possible while palming, in order to obtain the most benefit.

Q - My left eye turned in and was corrected by operation. Now it turns out. What method will cure this?

A - You need more than one method. Complete relaxation will relieve the strain and correct the squint.

Q - Is a great amount of floating specks indicative of cataract? When I am weary these look like a flock of bees crossing my eyeballs.

A - No. Your particular strain produces floating specks. A different strain produces cataract.

Q - Would the reading of fine print at four inches be helpful?

A - The reading of fine print at four inches is usually helpful.

Q - How long is it necessary to read the test card before obtaining benefit?

Q - Some patients by palming and resting their eyes have obtained benefit in a few minutes.

Q - I notice that my squint eye does straighten after palming, but reverts when I stop. How can I tell when and how I strain?

A - Avoid staring after palming and blink all the time. You can demonstrate that staring is a strain by consciously doing it for a few seconds.

Q - Please explain what you mean when you say "imperfect sight, imperfect memory."

A - If you see an object imperfectly, blurred or gray instead of black, you cannot remember it perfectly. You will remember it as you see it. The blurred mental image causes the object to continue to be seen unclear because the memory, imagination, brain is creating, storing a unclear image, picture of the object. Remembering, imagining the object clear, shifting on it causes the brain to store a clear picture of the object in the memory. The object becomes clear, the eyes then see the object correct, clear and send a perfect clear picture to the brain. The brain stores a perfect clear picture of the object in the memory. The next time the object is seen, the eyes, brain use the clear memory picture to activate correct eye function, perfect shifting on the object - the eyes see the object clear.

Q - My hands become tired when I palm. Can I sit in a dark room instead of palming? Can I cover my eyes with a dark cloth?

A - No. I have found this to be a strain.

Q - Why is fine print beneficial?

A - Fine print is beneficial because it cannot be read by a strain or effort. The eyes must be relaxed.

Q - How can one overcome the stare if it is unconscious?

A - Blink consciously, whenever possible, especially when reading. Never look at an object for more than a few seconds at a time. Shift your gaze. Shift from part to part, object to object. Blink, relax.

Q - I have attained normal vision, but after reading for a while, my eyes feel strained. Would you still consider I had normal sight?

A - If your eyes feel strained, you are not reading with normal vision. Check your posture, relaxation, positive state of mind, stay interested in the subject being read. Blink. Avoid staring, squinting, effort to see, worrying, thinking about the eyes, clarity of vision. Look to the distance occasionally.

Q - If type can be seen more distinctly with the eyes partly closed, (squinting) is it advisable to read that way?

A - No, it is not advisable to read that way because it is a strain, and alters the shape of the eyeball.

Q - Seeing stationary objects moving appears to me to be merely self-hypnotism. I can't do it.

A - When riding in a train the stationary telephone poles appear to move in the opposite direction. Of course this is an illusion, but it is a benefit to the eyes to imagine all stationary objects moving.

Q - I am always conscious of eyestrain in church.

A - Eyestrain is caused by a stare or an effort to see. Close your eyes frequently and rest them. Shift, blink when looking at the priest, altar, windows. If you are bored with the sermon because you have heard it many times before, let the mind daydream to something pleasant.

Q - Is there any power in the lens of dark sunglasses? Are they harmful?

A - Yes. Dark glasses are very injurious to the eyes. Sunglasses, tinted, colored, UV blocking and even plain eyeglass lenses prevent healthy full spectrum sunlight from entering the eyes and causes harmful unbalanced, partial spectrum light to enter the eyes, brain, body, lowers tolerance to sunlight and all light, adjustment to light/dark, causes watering eyes, impairs mood, sleep cycle, functions of the brain, memory, imagination..., impairs health and function of the retina, lens, cornea, eye muscles, iris, resulting in unclear vision, astigmatism, cataracts, macula degeneration, conical cornea and other eye problems.

Q - By blinking do you mean shutting and opening the eyes quickly, or is it done slowly like a wink?

A - Blinking is done quickly, and not slowly link a wink. Watch someone with perfect sight do this unconsciously, and follow his example.

Q - I have noticed that when I palm, my eyeballs hurt from the pressure. When I loosen this tension the light filters in.

A - Palming is done correctly with the fingers closed and laid gently over each eye, using the palms like a cup. If this is done properly there is no pressure and the light

Fig. 6. Mexican Indians

With normal sight when tested all the members of this primitive group are now either squinting or staring.

Fig. 7. Ainu, the Aboriginal Inhabitants of Japan  
All show signs of temporary imperfect sight

is shut out. Its ok if a little light shines through.

Q - I have improved my sight by palming, but when I read for any length of time the pain returns.

A - When you read and your eyes pain you, it means that you are straining your eyes. More frequent palming may help you more continuously.

The same boy making himself myopic voluntarily by partly closing the eyelids and making a conscious effort to read the test card at ten feet.

Fig. 37 Myopic Astigmatism comes and Goes According as the Subject Looks at Distant Objects With or Without Strain

No. 1.—Patient regarding the Snellen test card at ten feet without effort and reading the bottom line with normal vision.

No. 2.—The same patient making an effort to see a picture at twenty feet. The retinoscope indicated compound myopic astigmatism.

**Squinting** - To squeeze the eyelids close together, narrowing the space between the eyelids. This reduces the unfocused light rays in abnormally functioning eyes (the pinhole effect) and brings temporary clearer vision while squinting but leads to eye muscle tension, strain, muscle tension in the face, neck... and increased blur. Avoid squinting. Shift part to part on a object to see it clear, maintain clear eyesight and healthy eyes.

## Case Report

By Edith Reid

*The following is a report of a case treated by Mrs. Edith Reid, one of Dr. Bates' representatives, who is now practicing in Johannesburg, South Africa.*

Many times I have been asked: "Is it really possible to cure cataract by Dr. Bates' method without an operation?" I can prove that it is. One morning in January during our very hot weather a lady called to see me. Upon being told that as I was leaving town very shortly I could not see her, she became very much upset and declared that she would go blind, as she had cataract. As soon as I heard it was cataract, I had her shown into the room, knowing that if she was not taught the Bates Method she would become worse if left until I returned some months later. This lady made her living by teaching singing.

When tested, she read the fifty line at ten feet from the test card; then her vision blurred as she began to strain terribly. She was taught to palm and rest her eyes. Hers was a bright, sunny nature and she was very happy at finding such an easy simple way of resting her poor tired eyes.

She was told to discard her glasses, but declared that would be very difficult as she had worn them for thirty seven years. However, she said that she would be plucky and try. She was asked to come again the following day, which she did. She was all smiles and said that she was sure she was better as her eyes felt moist and so rested.

She was taught the swing and was told to swing and palm all day long if possible. She had a journey of about two hours on the train every morning to come into the city to teach, so she was told to look out of the windows and see everything moving, and when talking to friends to be sure to close her eyes often, so as to keep herself from staring.

Every morning for the next eight days she came to my rooms to get the sun glass treatment and rest for at least an hour before starting her teaching. She was always bright and cheerful and came every day saying how much better she was.

On the ninth morning she was tested and she was able to read the test card 15/10 and diamond type print at twelve inches. She became very much excited and told of how she had been told by an eye specialist that she had cataract and that she would go totally blind and then they would operate. She was also told never to take off her glasses. When asked how she found time to practice, she answered: "I work with my eyes all day long. When I play the accompaniments for my pupils, I swing and then when I speak to them I close my eyes."

She is now able to read the newspapers and any small print with perfect comfort. She says her friends come to see her teach as they had never known her without glasses. She is most grateful to Dr. Bates.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MAY, 1928

## Color Blindness

Some people are unable to distinguish red from blue or other colors. Many doctors explain color blindness to be due to something wrong with the retina, optic nerve or brain. They believe that organic changes in the retina are the principal cause. But this is not always true because, in some cases, cures occur without any apparent change in the retina.

I have found that color blindness occurs in a great many cases in an eye apparently normal. There are, however, a number of

individuals who can be demonstrated to have color blindness as a result of a disease of the retina caused by mental strain. These cases cannot be cured, however, until the disease of the retina is cured.

Some patients with color blindness are sensitive to a bright light. On the other hand, there are patients with color blindness who are more comfortable in a bright light. **These patients are usually relieved by the practice of sun treatment, central fixation, palming, the long swing, or any other method which brings about relaxation.**

One patient had a normal perception for colors at three feet and at ten feet. But at a nearer point than three feet she was color blind, the blindness being most marked at three inches. At a distance greater than ten feet the color blindness was evident. After her eyestrain was relieved by relaxation her color blindness disappeared.

People who have been born color blind as well as those who have acquired color blindness have all been cured by the practice of relaxation methods.

## The Stare

By W. H. Bates, M.D.

Much can be written about the stare. In the first place, when a patient stares, an effort is always made to hold the eyes still without moving them. It is impossible to hold the eyes perfectly still. Trying to do the impossible always requires a strain. This strain can be demonstrated to be a **mental strain which affects all the nerves of the body as well as the eye. With a mental strain, the memory and imagination become imperfect and imperfect sight results. Pain, fatigue or dizziness, are acquired or made worse.** With relaxation of all the nerves, the sense of touch is improved, but with the stare or other efforts to see the sense of touch is lost while the sense of pain is increased. Staring=not moving/shifting the eyes. Keeping the eyes, visual attention on only one part of an object without shifting on the part, without shifting to a new part, or trying to see all parts of an object or all objects in the central and peripheral field clear at the same time without shifting part to part, object to object. This is diffusion, eccentric fixation. These two types of staring result in strain and unclear vision.

**Glaucoma**, acute or chronic, has been consciously produced by the stare. The fundamental symptoms of glaucoma may be present with or without increased hardness of the eyeball, contraction of the nasal field, or glaucomatous excavation of the optic nerve. In glaucoma the blood vessels of the retina appear to be arranged in the form of a right angle just as they dip down into the nerve. The whole papilla where the optic nerve enters the back part of the eye is all white instead of pink. Changes which are seen in the optic nerve are organic. The contracted field may be considered to be functional because there are many cases which recover and the field becomes clear.

This suggested that in glaucoma the patient be recommended to alternately stare and relax. When he is staring and trying to improve the vision by an effort, all the symptoms of glaucoma may be increased. If the stare is the cause of glaucoma, relaxation should always lessen the severity of the symptoms.

There are some patients who have been using the stare to improve their vision for a sufficient length of time to acquire the habit without being conscious that an effort was being made. Each individual case may require individual treatment in order that the patient may become, by practice, conscious of the stare when the vision is lowered. Of course, if the stare increases the glaucoma, by stopping the stare we would expect the eye to improve. If it does not improve, the patient is still staring, whether he knows it or not. Sometimes by increasing the distance of the test card from the eyes while the patient is staring, he often becomes able to demonstrate that the stare is present when the vision becomes worse.

Many adults past middle life unconsciously stare and produce glaucoma. By practice they become conscious of the stare. While the stare, when it is strong enough and sufficiently prolonged, usually increases the hardness of the eyeball, in the matter of treatment the great problem is to suggest measures which will enable the patient to demonstrate that the stare is the cause of increased tension of the eyeball in glaucoma.

Absolute glaucoma is a serious disease and the stare can become so great that a large amount of pain and total blindness will be produced. The pain may be so severe that many ophthalmologists feel justified in removing the eyeball to bring relief. While many cases of absolute glaucoma obtained much relief from pain after the removal of the eyeball, there were too many cases which still had severe trouble, even after such an operation. A strain which produces absolute glaucoma is really a mental strain and not a local one entirely.

**Trigeminal neuralgia** is also a very serious eye trouble. Many operations have been performed for its relief, most of which were failures. Some patients have had nearly all of the fifth nerve with its branches removed in order to relieve the pain. There are many patients who have not obtained permanent relief from pain after various methods of orthodox treatment were employed. In the severest cases the branches of the fifth nerve at their origin in the gasserian ganglion in the brain have been removed, as well as the ganglia, without any permanent benefit whatever. I have discovered that the stare was the cause of the brain tension and that when the stare was relieved, all the symptoms of trigeminal neuralgia were relieved or cured and the vision became normal.

**Conical cornea** has for many years been considered incurable. A great many operations have been performed in which a small part of the cornea was removed with the expectation that when it healed the conical shape of the cornea would be corrected and the vision would thereby be improved. These operations were usually a disappointment. Conical cornea has been treated by relaxation methods and with great success.

**When the forefinger of one hand is held about six inches to one side of the face and about six inches straight ahead, the patient, by moving the head and eyes from side to side slowly or rapidly, can imagine the movement of the finger from side to side. This movement of the finger is called the variable swing and is specific for the benefit of all cases of conical cornea. It owes its value to the fact that when the finger appears to move, the injurious stare is prevented.** The length of time necessary to improve the vision with the help of the variable swing usually is not very long.

**Iritis** occurs quite frequently. The cause has heretofore been ascribed to syphilis, rheumatism, or some other constitutional disease. Chronic cases are seldom cured until after months of persistent treatment. Pain in acute iritis may be very severe and the vision is usually lowered. While treating patients in one of the out-patient departments of a city hospital, one of them applied for treatment of iritis which had produced so much blindness that he required an attendant to help him. The eyeball was very red, the pupil contracted, and the vision very imperfect. He suffered very much from

Variable Swing with finger to side of face. Move the head left and right and see the finger move opposite.

Variable Swing with finger in front, center of face, between the eyes, eye level.

photophobia or sensitiveness to light and kept his eyes covered most of the time.

I turned him over to my assistant with directions to **obtain relaxation by palming, swinging or the memory of perfect sight**. One-half hour later the patient disturbed the Clinic by laughing frequently, because the symptoms of iritis had almost entirely disappeared. He walked about the place, telling anyone who would listen to him about his prompt recovery. **This patient was able to increase the symptoms of iritis by the stare and lessen them by relaxation.**

#### Surgeon Creates Corneal Astigmatism

It may not be generally known that **the stare is the cause of corneal astigmatism**. With the aid of the ophthalmometer, most cases of corneal astigmatism can be diagnosed and measured. The ability of some people to produce corneal astigmatism is interesting. Some years ago a house surgeon in one of our largest hospitals acquired considerable notoriety or fame by his ability to produce temporarily a considerable amount of corneal astigmatism by staring at the opening tube of the ophthalmometer. He spent many hours experimenting on his eyes and he had become able not only to produce astigmatism at an angle of 90 degrees but also at an angle of 180 degrees. It required many months of constant practice before he became able, with the aid of the stare, to produce astigmatism with an oblique axis. Although he enjoyed the experimental work, which had for its object the cure of corneal astigmatism, so many doctors criticized him adversely that he stopped.

It was believed at one time by many physicians that **myopia** was caused by straining to see at the near point. Experiments to produce near-sightedness by an effort to see at the near point were failures. All the men, and there were many, who tried to produce near-sightedness or to lengthen the eyeball by efforts to see at the near point and so produce myopia, found instead the opposite condition, hypermetropia, (unclear close vision) with a shortening of the eyeball. The stare can produce a different kind of strain in each case and therefore cause a different eye defect or disease.

Some years ago a friend of mine called to see me and to learn about my experiments. I said to him: "Doctor, would you like to see a **case of cataract produced and cured?**" I took him into a dark room where one of my patients, a woman about seventy years of age was seated. After he had seen her he recognized her as one of his former patients. He told me in a low voice that arrangements had been made for taking her into a hospital and operating upon her eye.

I gave him an ophthalmoscope with a plus 18 convex glass which produced a very much enlarged image of the cataract. I asked the doctor if he could see the cataract, and he replied that the area of the pupil was completely filled with the cataract, and that there was no red reflex. He said that he believed that one would be justified in operating for its removal.

"Before we do that," I said, "suppose we look at the lens again." So we looked at the lens again with the ophthalmoscope and again he showed me that it was a proper case for operation.

"Well," I said, "suppose we keep looking at the cataract for a few minutes." I asked the patient if she had a good memory for flowers. She replied that she had. I asked her what flower she could remember best. She answered: "I believe I can remember a yellow chrysanthemum better than any other flower." I then said to the doctor: "how is the cataract?" "Why," he said, "it has disappeared." He was evidently very much puzzled.

I then asked the patient if she could remember my first name. She answered: "No." I said, "Suppose you try." She immediately began to stare and the upper part of the lens became opaque and all the muscles of her face were under a strain.

We investigated this case for half an hour or longer and came to the conclusion that **the memory of perfect sight was a cure for cataract and the memory of imperfect sight, which is usually associated with a stare, the cause of cataract.**

The relief of eyestrain or the stare has benefited so many heretofore considered incurable cases that the conclusions made should be investigated. If it is true that the stare can cause so much pain or suffering it is a breach of medical ethics for any doctor to deprive a man or women of relief by the use of such simple successful methods of treatment.

## Staring Relieved By Treatment

By Emily C. Lierman

A woman who had been suffering from **pain and imperfect sight** was sent to me for treatment. She suffered more at business than at any other time, and glasses did not help her much. Having charge of a tea room she was continually greeting patrons and placing them at tables. At times she seemed to have no trouble at all with her eyes and was able to read any part of the menu to patrons who asked her to do so, without using her glasses, which she wore most of the time. She had worn glasses off and on for four years and disliked them exceedingly, because they did not become her. Shortly before coming to me, she was told by an eye specialist that she would have to wear bi-focals. She was ready then to try most anything rather than wear them.

Her vision for the test card was 15/20 in both eyes, but with fine print and ordinary type she did not do so well. I began treating her by having her palm and while her eyes were closed and covered, I explained that some patients were not helped by palming, but if that were so in her case, we would try something else. She had a good memory for objects and people's faces, but her memory for names was not so good.

I asked her to describe to me all the sections of the tea room that she could remember. In this way, her memory and imagination would improve for other things which were not remembered or imagined so well. She described in detail how the tables were arranged and the design of the table silver. She could not remember the pattern of the tablecloths and napkins, although when she purchased the table linens, she purposely selected a certain pattern because it appealed to her. This worried her, but I explained that after she had learned how to relax under unfavorable conditions, she would be able to remember such details. I directed her to keep her eyes closed for more than half an hour, at times keeping perfectly still without speaking to me.

(I watch patients very closely while they are **palming** to see whether they are in a comfortable position and if not I try to arrange it so. I find that when the knees are crossed, the position soon brings on an unconscious strain; therefore I direct the patient to **keep the knees uncrossed**. Then I arrange the **feet so that they are comfortably placed either on the floor or on a footstool or hassock**. The patient is usually most comfortable in

an armchair and if the arms of the chair are not upholstered, **I place a cushion under one elbow in such a way that the patient is most comfortable.** This brings the patient in a position leaning over to the right side or to the left, so I try to have the patient change the position while relaxing by reversing the cushion to the opposite arm of the chair. With children I manage a little differently, especially when not tall enough to rest their feet on a footstool.)

It is best to place the cushion on the lap or a table for both left and right elbows to rest upon. This keeps good posture, evenly aligned and relaxed body, shoulders, neck, head.

The test card which I used for this patient had an extra line of letters smaller than the 10-line letters, which are read by the normal eye at ten feet. After this woman had palmed sufficiently, I removed the foot stool and while her eyes were still closed I told her to stand up and to start swaying her body slowly with an easy sway of the body from left to right. Then I told her to open her eyes and look from one edge of the Snellen test card to the other and to tell me what the letters were as I pointed toward them. She read every letter of the test card with each eye separately without any difficulty whatever.

The patient was so excited over her sudden improvement in sight and the relaxation which she felt of her whole body, that she thought one lesson was all that would be necessary for her. I thought that the improvement during her first treatment was only temporary and told her so. However, I was willing to give the patient the benefit of the doubt and told her that if her vision remained normal and she felt no more strain or discomfort, that it surely would not be necessary for her to take another lesson.

Early the next morning my telephone rang and it was she, explaining her discomfort and strain and begging me to see her again. I was surprised that the change came so soon. I thought that she would have at least a few days of relaxation and freedom from strain, but she had been at a bridge party after seeing me and something had happened to her during the course of the evening which brought her quickly to me the next day.

I feared that it would worry her if she could not do so well during her second treatment with the large Snellen test card, so we worked together with another part of the method. This time we used fine print. I sat directly in front of her as she looked at the little card with fine print, but it was pitiful to see her staring at it, trying to read.

Staring is such a common thing and most people stare unconsciously at times. A great many people stare unconsciously most of the time and cause much or all of the discomfort which soon brings on chronic trouble with the eyes and sometimes causes blindness. If school teachers were instructed to remind pupils at intervals during the daily sessions of the permanent punishment to their eyes as the result of staring, it would be avoided in time and less eye glasses would be prescribed for school children.

People do not wait until they are physically tired out before they sit or lie down to rest, but most people do not know what to do about their eyes when they are mentally tired. **In some cases just closing the eyes frequently for a second or two is all that is necessary to retain good vision for life.** This I know to be true because my grandmother who lived until she was 79 years of age did not wear glasses at all until she was over 70 years of age and then they were not fitted by an oculist, but were purchased at the price of ten cents from a solicitor who came to her door. She used them only when threading a fine needle. Without glasses, she could see fine stitches while sewing, whether the thread was black or white. What I particularly remember was that she blinked her eyes often, which I thought at the time was a mistake or an affliction, but since I have become Dr. Bates' assistant, I know that she was doing the natural thing.

**If all mothers would watch their babies as they begin to notice things and avoid any possible stare by just attracting the baby's attention to various things instead of just one thing, I believe that a great deal of squint could be avoided, as well as other eye troubles. Of course there are squint cases which have been brought on through illness or injury of some kind, but even these cases can be eventually cured by teaching the patient how to shift and blink and avoid the stare.**

I informed this patient that her principal trouble was staring and that I noticed it more on her second visit than I did at the first. She was told to close her eyes and while they were closed to remember a white cloud or a piece of white cloth, such as her handkerchief, which was in her lap at the time, then to open her eyes and instead of looking directly at the fine black print she was to look at the white spaces, and then close her eyes again and imagine them as white as her handkerchief.

She said she could remember a white cloud much better while her eyes were closed. While looking at her handkerchief she could see it perfectly white, but when she closed her eyes the memory of the white handkerchief was not so good. She said the whiteness became sort of gray or a soiled white, which made her uncomfortable while her eyes were closed. This proves again that Dr. Bates is right in saying that an imperfect memory of anything brings on strain and imperfect sight.

At first she could not do so well with the white spaces of fine print as she held the card six or eight inches from her eyes. We tried the other extreme then by placing the card close to her forehead, too close for her to read the fine print, even if she had no trouble with her eyes. **She was directed to move the card slowly, slightly touching her forehead over the bridge of her nose and opening her eyes with the slow movement of the card and closing them again. In this way she got flashes of the white spaces, and as she closed her eyes the memory of the white spaces improved so that when she drew the card away finally after practicing this method for ten or fifteen minutes she could read the fine print at six inches as well as she could at twelve inches.** Again she became excited as she did the day before and felt that at last she had grasped the idea of avoiding the stare and that she would not need to come again.

Two days later she telephoned me for another treatment, saying that she could not retain the good sight that she had while practicing with me. When she came for her third treatment, I tested her sight with the large test card, using various cards that I had. She did very well with the two cards she had read at her first visit, but with the strange cards her vision was the same as it was during her first visit, 15/20.

I decided to try a different method of treatment by having her imagine that my room was her tea room. A desk and small table with a few chairs were imagined to be tables at which she was to place imaginary patrons who were coming toward her. She told me that it was customary for her to have a napkin in her hand which served sometimes to wipe the top of a glass or to re-arrange a plate on the table. I gave her a towel to hold which served as a napkin and told her to shift from the napkin to the imaginary table, and in this way she learned how to shift and blink as she would have to do to retain her relaxation while at work in the tea room. She remembered this lesson very well and did her work in the tea room better for a few days.

When I saw her again, which was in less than a week's time, she said that she got along splendidly in the mornings, but in the afternoon after she had been busy for part of the day, she felt a strain coming on as usual, which caused a great deal of tension at the back of her head.

The method that we used that day at her fourth visit was used again at her last visit, the fifth treatment, when she did so well that I thought it unnecessary for her to come again. There were several pictures hanging on the wall of my room distributed in different places. I told her to imagine that she was in her stockroom where canned goods were stored. She explained how there were rows of canned tomatoes, which had the picture of a red tomato on the label. Then there were other shelves arranged with

cans of peas, which, of course, were green. There were shelves in another section of the room with canned vegetables, with various colored labels.

I told her to stand in the center of the room and to sway her body from left to right, blinking as she swayed and shifted from the canned peas to the canned tomatoes and other canned goods with various colored labels. She remarked that if she could keep up that good feeling of relaxation and freedom from tension and strain while she was practicing in the stockroom of her establishment, she would be amply repaid for the time she spent with me.

Her report over the telephone a few days later was favorable. She said that she had taken her car with friends and had driven many miles over a mountain trail, and if it had not been for her ability to blink and shift, she could not possibly have avoided an accident which would have thrown her car over the cliffs. I had told her to occasionally shift from the speedometer to the center of the road ahead and vice versa. I told her to remind herself continuously that it was not necessary to hold on very tight to the steering wheel, but to hold it loosely, which meant relaxation.

She said that her storeroom, she believed, was responsible for the absence of strain and tension late in the afternoon, when before she had seen me there was not a day that she was free from **pain in the back of her head**. She wore a fancy white apron during business hours, but always in the little pocket of her apron rested the small test card and a small fine print card which she would use when she had the opportunity to do so, practicing shifting from the white spaces of the fine type to sections of the room, which helped her to see things clearly and without strain. Carry a small rock or piece of jewelry, any colorful, shiny object with a lot of fine details. Shift on the details, colors, sparkles. Relax, blink, let the head, neck, shoulders relax, think something happy. This keeps close and distant vision clear.

I hope this article will be of benefit to those who do close work in offices, as well as people who do similar work to that of my patient.

## Case Report

As is generally known, **fevers** of all kinds are apt, if not treated with the utmost care, to result in **defective eyesight, hearing** and many other troubles, and it was at the age of six years, **after severe scarlet fever, that my eyes became weak, and subsequently developed a convergent squint**. In order to check this defect, it was found necessary to harness me to a pair of huge unsightly spectacles, with the usual thick corrective lenses. As a result of this drastic treatment my eyes weakened still more, becoming **myopic and astigmatic**, although the squint had certainly improved, but only at the cost of producing the other complications, for exceptionally strong lenses were used to this end.

I continued to pay periodic visits to the best available eye specialists in Johannesburg and Capetown, South Africa, all of whom at first encouraged me into the belief that eventually I would be able to discard them. Latterly, however, I received no such encouragement, but instead was warned that blindness could result if I went without them at any time. I reached the age of 26 years without having received any benefit from the wearing of glasses. In fact even more technical terms were introduced into the condition of my eyes, and I had come to the conclusion that nothing could be done for them, and that I would always wear glasses, and that continuous **headaches** were my lot. Such a dreadful state of mind for any one to get into!

Imagine my joy when at a tea party (they have their uses after all) I heard Dr. W. H. Bates' name and methods of treatment mentioned for the first time; that was in 1926, and of course anything to do with the eyes attracted my attention at once. At that time a Ms. Reid and Mr. Jardine, both students of Dr. Bates, had been carrying out exceptionally good work with the Bates Method. I immediately consulted with them, overlooking entirely the fact that at that time I had a great deal of work to do which would require the use of my eyes. The first thing I was told to do was to remove my glasses, and not to wear them again, and my implicit obedience in this regard surprised even myself, for since then I have never returned to my glasses. To Mrs. Reid and Mr. Jardine I am forever grateful for what they did.

I think what caused me to put such faith in Dr. Bates and his methods was the fact that I had been going to eye specialists for some twenty years, and instead of my eyes being benefited, they became steadily worse, which fact coincided with one of his observations.

I carried out the various exercises prescribed, under somewhat difficult circumstances, my entire day being consumed with office work. However, this did not deter me, for I did the **modified sway while sitting at the typewriter**, got into the **habit of blinking**, and **snatched a peep at the sun** as many times a day as time permitted, morning and evening. I **palmed** my eyes in between, for, understand, at this time my eyes were being called upon to do work which they had never done before. It was indeed a hard and uncomfortable period through which I was passing. In addition to all the **relaxation exercises**, I did **physical exercises** to keep me generally fit, and this helped greatly.

After three weeks, quite by accident, one day, I began to realize the value of relaxation, for up till then I was undergoing too much of a strain; from this time on I steadily improved. Of course I realized that after having worn glasses for twenty years I couldn't expect to be cured immediately and that it would be only by hard work and patience that eventually my eyes would be normal.

I became absorbed in this treatment, and felt that a great deal could still be learned. The fact that my own eyes were not yet normal, urged me to learn more of the methods of treatment by this wonderful system. When in London, I received more benefit from Mr. Price, another student of Dr. Bates, to whom I am very grateful.

I feel that if all the followers of Dr. Bates, and there are many, would co-operate, and perhaps pool the knowledge acquired by experience, we could help this treatment to spread throughout the world. What a benefit this would be to humanity at large!

Helen Kupferburger.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JUNE, 1928

### Subjective Conjunctivitis

By subjective conjunctivitis is meant that the conjunctiva is inflamed without the evidence of disease. Many people with subjective conjunctivitis will complain of a foreign body in the eye and yet careful search with the use of a good light and a strong magnifying glass will reveal no foreign body present. Some people with subjective conjunctivitis complain that they have granulated lids and that they suffer from time to time from the presence of little pimples on the inside of the eyelids and the pain that they suffer is out of proportion to the cause that they give to it. Among the many symptoms of subjective conjunctivitis may be a flow of tears from very slight irritants. However, the tear ducts, with the aid of which the tears are drained from the eye, are usually open in these cases and they are sufficiently open to receive a solution of boracic acid which may be injected through the tear duct into the nose. This shows that the tear duct is open normally, and therefore can drain the tears from the eyes.

Dr. C. R. Agnew, at one time professor of ophthalmology at Columbia University, gave many lectures on subjective conjunctivitis in 1885 and 1886. The treatment which he advocated was dry massage of the whole body and I can testify that it was an excellent remedy. However, the treatment which I found was the greatest benefit was the aqueous extract of the suprarenal capsule, or adrenalin, the properties of which I discovered, using one drop in each eye three times a day.

Many cases were benefited by the sun treatment, by central fixation and by the practice of the universal swing. Modern prescription and non-prescription nose/sinus sprays contain toxic chemicals that travel from the nose into the eyes, ears, brain, body resulting in health impairment of body, brain, ears, eyes and unclear vision. Eye-drops are addictive and destroy the eyes natural tear structure and production.

### Swinging

By W. H. Bates, M.D.

The muscles on the outside of the normal eye are at rest when the sight is normal. Any contraction of one or more of these muscles by pressure, by operation or by electrical stimulation always produces an error of refraction. The removal of the crystalline lens may be done without changing the form of the eyeball.

The normal eye has normal sight when it is at rest. It is at rest, or relaxed, when it is moving to prevent the stare, strain, or effort to see. When the patient becomes aware that his eye troubles are always caused by one of these three, all of which are difficult, he becomes able easily to maintain the swinging of all objects. (Oppositional Movement)

**Shifting or moving the eyes from side to side with a similar movement of the head improves the sight when done properly.** It can be done wrong when the eyes move in a different direction to the movement of the head. In some cases, when turning the head to the right, the eyes may turn in the opposite direction, for example, at the same time. Cases have been observed where one or both eyes appear stationary while the head may be moving.

One patient complained that when he planned to move his eyes with the movement of his head that he was not conscious that his eyes were moving as desired or that the eyes were moving and not stationary.

In some cases the eyes would move irregularly and unconsciously a longer or a shorter distance than the movements of the head. When one or more of the patient's fingers were pressed lightly on the closed eyelids, the eyes could be felt to move rapidly, slowly, or in any direction.

The eyes may move to the right while the head moves opposite, or to the left. Swaying the head and body a long distance to the right or left may be accompanied by an apparent movement of stationary objects in the opposite or in the same direction. Stationary objects with a prominent background move opposite, while objects partly covered may appear to move in the same direction.

Some people have difficulty in practicing the swing successfully. They cannot imagine any stationary object to be moving no matter how much swinging is practiced. They usually complain that they cannot imagine stationary letters or other objects to be moving when they move their head or eyes. They feel absolutely certain that the stationary object is always stationary and cannot be expected to move when the body sways from side to side in a long or short movement.

It is absolutely necessary that all persons with imperfect sight should become able to imagine stationary objects to be moving. When an effort is made to imagine stationary objects to be stationary, the eyes become fixed or stare at the letter or other object and make an effort which always fails. A very successful method of teaching nervous people how to imagine stationary objects to be moving is as follows;

**The Snellen test card** is fastened to a support about fifteen feet away from the patient. When the patient looks at a point about three feet to the right of the test card, the card is to the left of the point regarded, and advances farther to the left when the point regarded is moved to the right. When the patient is directed to regard a point to the left of the Snellen test card, the card moves to the right side of the point regarded.

The greater the shift from one point to another, the wider becomes the swing. By repetition, the patient becomes able to realize that whenever a point regarded is to the right of the card that the card and all other objects are to the left of the point regarded. When the eyes move to one

Long Swing

Swing the body left and right. Head/face, eyes, body move together, at the same time, in the same direction.

See oppositional movement; objects in the visual field appear to move 'swing by' in the opposite direction. Do not stop to look at the objects. Keep swinging, relax and let them move.

Sway/rock left and right.

•Look 3 Feet to the right of the eye chart. Then, look 3 feet to the left of the eye chart.  
•Notice the chart moves in the opposite direction the eyes, head, body move to.  
•Shift long, left and right on the sides of the chart and see a long, wide oppositional movement. (see dots, shift dot to dot)  
•Then shift shorter, left and right on the edges of the chart and see a shorter opposite movement. (see dots)  
•Then shift shorter, smaller- left and right, top and bottom on the letter C and see a short, small opposite movement. (see dots)  
•Shift point to point on a small part of the C and see a tiny opposite movement.  
Small eye shifts on a object bring clearer, more fine detailed vision. Central Fixation. Practice at far and close dist. areas.

side of the card, the card moves to the opposite side and this movement of the card can always be demonstrated by insisting that the patient imagine the Snellen test card moves to the left every time the eyes move to a point to the right. (The original sentence was; ..insisting that the patient cannot imagine the Snellen test card moves...) The word cannot is thought to be a misprint and has been taken out.)

This method is always a truth without any exceptions because no matter how much the patient may insist that he is right, he has to acknowledge that when he looks to the right, the Snellen test card moves to the left, and this movement is so decided that it very soon becomes impossible for the patient to fail to imagine stationary objects to be moving whenever the eyes move from right to left, from left to right, or in any other direction. This demonstration may be made very convincing with a little time and patience. There are so many of these patients who have difficulty in imagining stationary objects to be moving when the eyes move from side to side or in other directions that the swing should be practiced.

**Long Swing:** The patient stands with the feet about one foot apart and turns the body to the right - at the same time lifting the heel of the left foot. The head and eyes move with the body, synchronized: eyes, head, body move together, same time, same direction. One should not pay any attention to the apparent movement of stationary objects. Do not look at the objects that are showing oppositional movement. Relax, swing and let the objects 'swing', pass by in the opposite direction. The left heel is then placed on the floor; the body is turned to the left as the patient raises the heel of the right foot. I usually advise patients to practice this right and left swing one hundred times morning and night, counting one to the right, two to the left, and so on.

**Variable swing:** The patient holds the forefinger of one hand six inches from the right eye and about the same distance to the right, as he moves the head a short distance from side to side. The finger should appear to move in the opposite direction to the movement of the head. This can also be done with the finger held between the left and right eyes, at eye level.

**Universal Swing:** The patient stands and sways the body from side to side. While the body is moving, the eyes are moving, and stationary objects nearby (close objects) which have a background (distant object beyond close object) appear to move in the opposite direction to the movement of the head and eyes. Objects located at more distant points which have no background always appear to move in the same direction as the movement of the body.

If the finger is held before the eyes while the head is moved from side to side, one may, by practice, become able to imagine that everything connected with the finger, either directly or indirectly, is moving in the opposite direction, while the background is moving in the same direction. **The universal swing is very beneficial and usually prevents and cures pain, dizziness, and other nervous symptoms.**

**Circular Swing:** There is one objection to the universal swing and that is that at the end of the count to the right or left, the patient in some cases stares. This stoppage of the swing may be corrected by the practice of the circular swing, when all objects are imagined to move continuously in a circular direction. The circular swing may be remembered with the eyes closed and differs from the other swings in that the finger, Snellen test card, or other objects appear to move in a circular direction.

In the circular swing, the head and eyes are moved in a circular direction.

**Square Swing:** In the square swing, the head and eyes are moved in a horizontal line from one side to the other and then downward, across, upward, and across, without a stop being made in any part of the swing. Many patients can practice a square swing when they find it difficult or impossible to practice a circular swing. Either the circular or square swing may be practiced with the eyes open or closed.

(The Figure Eight - Infinity Swing is an improved, modern version of the circular and square swings. See last page this book.) There are more examples of different swings throughout this book.

See index or use word search in Adobe.

Not all persons can practice any particular kind of a swing successfully with the eyes open, but with the eyes closed, with the help of the memory and the imagination, almost any swing can be practiced with benefit. It is interesting to observe that swinging the head and eyes a long distance from side to side is more easily accomplished than a short movement, although a short swing when practiced properly is more beneficial.

Practice the swings with the eyes open, closed, open and remember, imagine and see oppositional movement of objects.

Variable Swing with finger to side of face. Move the head left and right and see the finger move opposite.

Variable Swing with finger in front, center of face, between the eyes, eye level.

Sway/rock left and right.

THE FIGURE EIGHT

## Case Reports

Some years ago, a patient came to me suffering from **progressive myopia** with well marked imperfect sight. The patient was unable to practice central fixation, to remember, imagine, or see perfectly. The square swing, with the relaxation that it brought about, corrected all this patient's troubles.

A patient who was born blind was treated several years ago. He had the symptoms of chronic **glaucoma**, **partial atrophy of the optic nerve** and **progressive myopia**. He was unable to imagine stationary objects to be moving when he moved his head and eyes from side to side or in other directions. He had great difficulty in consciously controlling the movements of his eyes. When he desired to look to the right both eyes would at once look to the left and the movement was very irregular.

He was also troubled with **nystagmus**. Sometimes the nystagmus was very irregular, but usually both eyes moved jerkily from side to side. He was unable to hold either eye stationary. The eyes appeared very small because the margins of the upper and lower lids were close together; it seemed as though the **lids were partially paralyzed**.

When he was asked to move his eyes consciously, he soon became frightened and found it difficult and at times impossible to

move his eyes at all. When pressing down his upper lid, while I was determining the hardness of the eyeball, I was surprised to notice that the pressure of the forefinger on the eyeball stopped the nystagmus and enabled him to move his eyes in various directions, which he had not been able to do before. (May help crossed/wandering eyes; lightly touching the top of the closed eyes on the eyelids and imagine shifting on objects and feel the eyes move correct.)

When the right eye looked twenty feet to the right of the Snellen test card, the card appeared to be to the left of where he was looking. When he looked as far to the left, the Snellen test card was about twenty feet to the right of where he was looking. By practicing the long swing alternately, he acquired, after a few weeks, a great deal of conscious control of the movement of the eyes. Later, after the movement of his eyes became more easy and continuous without effort or strain, the eyes seemed to become more widely open. By continued practice his other symptoms gradually disappeared.

A girl, aged ten years, came to my office with her father. He desired that I examine the child and find out if her sight was normal or not. I tested her sight and she read the bottom line at ten feet. When I asked her if the last letter on the bottom line could be a letter "O," she answered that it could not be a letter "O," because it was a figure "6."

I said: "All right, is the figure '6' stationary or does it move?" She breathed deeply, because it was a new experience for her to imagine stationary objects to be moving. After a while she said: "Yes, the figure '6' moves about its own diameter from side to side." I said to her: "Can you stop the swing?" Almost before I asked the question, she looked away from the card. "Why did you do that?" I asked.

She replied: "When I tried to stop the swing, it gave me a headache; I lost the figure '6,' the whole card was blurred and I didn't like it." Thus I demonstrated that normal sight cannot be maintained without a continuous, slow, short, easy swing of all stationary objects regarded. To stop the short swing requires a conscious or an unconscious effort, which in turn may produce discomfort and pain in the eyes or head.

One patient was suffering from **chronic glaucoma, cataract, progressive myopia and chronic iritis**. One eye was totally blind and was unable to locate a strong light in any part of the field. The other eye had vision from one side only, the temporal field. This patient received most benefit from the long swing; other methods of treatment seemed to be of no benefit.

One of the most difficult patients to relieve was a patient who had been **injured in one eye**, so that **sympathetic ophthalmia** appeared after some years. The vision in the right eye was perception of light only; the left eye had been enucleated, but the operation had not been performed sufficiently early to be of much benefit. The eyeball was soft, like mush, showing that the ciliary body had been very much diseased. This patient learned the universal swing at the first visit. With the help of this swing, the hardness of the eyeball increased and his vision became better. The benefit which he received from this particular swing was the only benefit that amounted to anything.

### Myopia and Presbyopia Relieved By Treatment Floating Specks Relieved By Emily C. Liernan

A woman, aged 51, whose vision had been impaired for a good many years, thought that she would try the Bates treatment and see if she could in time discard her undesirable glasses. When I tested her eyes, her vision was 15/70 with the right eye and 15/200 with the left. When I first meet a person I have an unconscious habit of looking at the eyes and I noticed particularly that this woman **seldom blinked**. She had worn glasses for twenty years, but recently she had worn them only at the theater, movies and in places where the light was dim.

She complained of **floating specks** which at times seemed to her like miniature airplanes or tiny round white circles with gray centers. She boasted about being able to multiply these imaginary things floating before her eyes and to see them just as clearly with her eyes closed as she could with them open. It is hard to even imagine how terribly she strained in order to bring about such a condition.

She told me that previous to her coming to me she had visited an eye specialist who examined her eyes thoroughly and who told her that he could see no condition of her eyes that would cause floating specks, and that the retinas of her eyes were perfectly clear. He diagnosed her case as progressive myopia and then gave her a stronger pair of glasses than she had been accustomed to wearing. It was because of these stronger lenses and the discomfort that she experienced in trying to get accustomed to the wearing of them that prompted her to come to me.

The black card with white letters was used in testing the sight of my patient. While she was resting her eyes by palming, I placed the test card ten feet from her eyes instead of fifteen, just to see how much more she could read at a nearer distance. After a short period of palming, I asked her to read the card again and her vision had improved to 10/50. I was glad to see this improvement even though it was slight. However, I thought that it might have been her right eye which was reading the 50 line, even though she was reading the card with both eyes.

I wanted to be sure that improvement had been made, so I asked her to cover her right eye and read the card again with the left. She read up to the 50 line just the same, which I thought was a good improvement in so short a time. I told her how other patients had improved by practicing many times a day at home and that if she would follow my directions, and come to see me for a few lessons that she would make steady progress.

A few days later she came again and I noticed that she had acquired the **habit of blinking**. This was encouraging, because it is not often that patients who have only had one treatment can remember to keep up this **good habit** (correct vision habit) which is done unconsciously by people who have no trouble with their eyes. I did not mention this to the patient because I was afraid to make her conscious of the fact and again

**Long Swing**  
Swing left and right in front of the eyechart and see it move in the opposite direction the eyes, head, body move to.

Look at the white spaces between sentences of fine print at a close distance to relax the mind, eyes and then look at, shift on letters on a distant eyechart and see the letters clear.

Read fine print close to the eyes, in the sunlight daily or a few times a week for clear close and distant vision.

unconsciously get into her bad habit of staring. However, I made note of this in my record and the last time I saw her I drew her attention to it, which pleased her.

During her first treatment I did not make any special effort to relieve her trouble with the floating specks, nor did either one of us mention it. Before I tested her sight at her second treatment, she said she had something to tell me. She noticed for the first time that in trying to increase the number of floating specks which she formerly was able to do, she had produced a terrific pain in both eyes and so she stopped doing it.

At my patient's second treatment I used the black test card and I gave her a card with diamond type to hold near her eyes. I gave her the usual advice, saying that she was not to try to read the print but only to look at the white spaces between the lines of fine type. Closing the eyes often and remembering the white spaces helped her to see the letters of the distant card, seeing one letter at a time and then looking to the white spaces of the fine type. She read 10/40 with each eye separately, seeing each letter clear and white. She remarked that the whiter the letters appeared to her, the more black became the background of the card.

At her first treatment I noticed that the sclera or white parts of both her eyes were bloodshot and looked as though she did not get enough sleep. I wrote this in my record of her case, but I said nothing about it to her. At this, her second visit, I noticed that the patient's eyes looked clear and the white parts were as white as my own eyes.

I placed her before a mirror and told her to blink and to look at her right eye and then at her left. This helped her to see that her eyes were moving while she blinked. It was then that she remarked how white the white parts of her eyes were. I enjoy treating a patient like her because there is a great deal of satisfaction in having the patient know that there has been an improvement in so short a time. She told me that her husband had read to her for one whole hour while she was palming or just keeping her eyes closed and resting her arms on her lap or on the arms of her chair.

I gave her more advice about what she was to practice at home and then two days later I saw her again. This time I asked her to hold the fine print as close as she could read it and to read what she saw on the little card. During her first treatment, I did not ask her to read the fine print because I thought she would have no trouble in reading it. I was much surprised to hear her say that she could not read it.

I was out-of-town treating patients at this time and as I was away from Dr. Bates, I was not allowed by the medical authorities to use a retinoscope or an ophthalmoscope, or to do any examining of the eyes of any kind. I was perfectly willing to abide by the law and was told particularly by Dr. Bates himself to do so. Therefore, I could not determine just what was wrong and why, when she was myopic, she could not read fine type as most myopic patients can. However, that did not worry me in the least because all the articles comprising my book were reports of cases treated by me during more than nine years when I did not at any time use any apparatus in the treatment or in the cure of these cases. I did, however, use a sun glass.

This patient was sitting near a window with her back to the sun. I asked her to stand up while I turned the chair the opposite way and told her to keep her eyes closed as she sat in the sun, while I used the sun glass on her closed eyelids. I timed this treatment and gave her exactly eight minutes of the sun, focusing the sun glass on the closed eyelids, at the same time advising the patient not to open her eyes even for a second. Then I pulled down the shade to shut out the sunlight and immediately after opening her eyes she became able to read all of the fine print. And this with just that one treatment with the sunlight. After that she gave her eyes sun treatment many times a day and remained in the sunshine as much as possible, discarding her parasol which she usually carried with her and also leaving off her hat whenever it was possible.

All patients do not have the advantages which this patient had, I know. Yet patients are cured who have no chance to take sun treatment during the day except at their lunch hour. Patients who have found it impossible to get any sun treatment during the day have been successfully treated and cured of their imperfect sight by the use of a strong electric light.

While I was away from Dr. Bates, doing his work at the seashore and in other places, it was astounding to see so many people wearing dark glasses called "sun glasses" to protect their eyes from the glare of the sun. What a mistake it is to wear these glasses, even though so many specialists advise such a procedure! One cannot always wear them; therefore it is best for the human eye to get accustomed to all kinds of light without protection of any kind.

During the time I was treating this patient, while she was rapidly improving at each lesson, I had the great pleasure of meeting a noted criminologist who was very near-sighted. He had difficulty in seeing things clearly while driving his car and doing other necessary things which required good sight, unless he wore his strong glasses. This man mentioned the case of his brother, who had read Dr. Bates' book, "Perfect Sight Without Glasses" and practiced the methods advised.

#### Sunning

He said that every day he practiced in the hot sun in the desert where all he could see was sand, distant mountains and the sky; he would close his eyes and allow the sun to shine on his closed eyelids, then open his eyes and look off at the distant mountains, alternately shifting from the saddle of his horse to the distant mountains. He was not only cured of his imperfect sight, but also became able to look at the sun by shifting and blinking without any tearing of the eyes or any discomfort whatever. He also noticed, being an expert in the different breeds of horses, that those which had blinders put on them acquired cataract, or could not see as well as horses who were free from any incumbrance as far as their eyes were concerned. After reading Dr. Bates' book he wrote to his brother and said that if the strong light of the sun was not injurious to an animal, why should it be injurious to the human eye? He was convinced that imperfect sight was caused by strain or an injury and if there were any sight at all that it could be improved by natural methods and not by the use of glasses.

To go back to my patient. She came for four days in succession for treatments, being encouraged at the progress she had made.

#### Sunlight Treatments

Sunning - Face the sun, eyes closed and move the head slowly side to side.

Sunglass - Eyes closed, head still. Sunglass with sunlight shining through the glass is moved quickly, 1-2 seconds on the eyelids.

Sunglass with eyes open - Head still. Eyes looking down, pupil under eyelid, away from the sun's light. Sunglass moves the sunlight quickly, 1-2 seconds on the sclera, upper white area of the eye.

Sunglass is used only in cases of blindness, by an experienced ophthalmologist, only when other methods have not helped restore the vision.

#### Sun Treatment

Pull the upper eyelid up, look down, pupil away from sun, let the sun shine directly on the upper white area of the eye. Then, release the upper lid, look up, head back and pull the lower lid down and let the sun shine on the lower white area of eye.

Sunning Face the sun, eyes closed, move the head side to side moving the sunlight over the entire retina.

At each treatment she improved, reading another line of the test card, by first reading the fine print as close as she could get it to her eyes. Shifting from a blank wall to the test card while she was standing and swaying her body slowly from side to side also helped in the improvement of her sight for the distance.

#### Switch Visual Attention at Close and Far Distances

Each day I varied the treatment. One day I placed her by a window and had her shift from the fine print up close to her eyes to the distant signs which I called to her attention, and to tops of houses and other buildings. An American flag waved in the distance and shifting from the flag to the flagstaff helped her to see the staff more clearly and by keeping up the constant sway of the body, blinking easily, but steadily all the while, she became able to see the harbor in the distance and also the boats which were moored near the shore. She told me that this was the first time in her life that she could ever see at such a distance.

She was the means of changing the mind of a skeptical husband who thought that the Bates treatment was a myth or something like it. However, he decided that if palming and swinging was a good thing for his wife and could make her so much more contented in her home duties than she was before, that perhaps it would help him to be a more agreeable person in his office as well as in his home. With just a few suggestions from me, my patient treated him successfully at home, and her last report was that he was reading his newspaper and book type without the use of his glasses.

I realized more and more that if Dr. Bates could live until the end of time that it would be his cured patients who would advertise him in the right and only way. Times without number there have been magazine and newspaper writers, as well as authors of books who were cured after being treated by Dr. Bates who offered to advertise him in the way that they thought best.

Many years ago, without realizing that it would harm him, Dr. Bates allowed these grateful patients to advertise him in their own way. They unintentionally caused him much worry and concern with the medical profession. The only way to make Dr. Bates' work known to the world is to have his cured patients talk about the benefit they received and in that way help others who are suffering from defective vision. (Optical Industry Trying to Hide Bates Method From the Public.)

During the last treatment I gave my patient she read the various test cards, 15/15, with the exception of the black card with white letters, which she was able to read 15/10. Also, the **floating specks had entirely disappeared after her third treatment.** This case was very interesting, because it is seldom that one has **presbyopia and myopia simultaneously.**

To carry out treatment successfully, I try to be careful to vary the method of treatment at each lesson. I find it true also that if I try out things by myself, without the help of Dr. Bates, or his suggestions in the matter, that I fail sooner or later. Our students will benefit greatly by doing the same thing always. If the student is in doubt as to whether he or she can cure a difficult case, it is always best to write or come directly to headquarters and find out what is wrong. It is Dr. Bates' desire *always* to help the students to cure any case which may be difficult.

Sunning

+Face the sun, eyes closed, move the head side to side, up and down, circular... Do the Sway.  
+Open the eyes and look away from the sun to the bright sky, clouds, tree tops.  
+Go outside in the sunlight daily. Full spectrum sunlight contains all wave lengths, frequencies, colors, mixtures of colors of the light spectrum. Full spectrum sunlight, not filtered through eyeglasses, contacts, sunglasses, windows keeps the eyes, brain, body healthy and vision clear.

## Questions And Answers

Q - Can hemorrhage of the retina be cured by Dr. Bates' method of treatment?

A - Cases of hemorrhage of the retina have been cured by Dr. Bates' method.

Q- Can a patient while practicing the Bates method carry on his daily work just the same?

A - Yes, most patients continue their work just the same without the use of their glasses even though they find it difficult at the start.

Q - Can the vision be improved without glasses after the lens has been removed for cataract?

A - Yes.

Q - Does Dr. Bates approve of dark glasses to protect the eyes from the glare of the sun at the seashore?

A - No. Dark glasses are injurious to the eyes. The strong light of the sun is beneficial to the eyes, although it may be temporarily painful and blinding.

Q - What causes styes?

A - Infection, which is always associated with eyestrain.

Q - I am practicing the methods in Dr. Bates' book to cure myopia and astigmatism. Sometimes, for short periods, I see perfectly: then things fade away. Can you explain this?

A- This is what we call getting flashes of perfect sight. With continued practice these flashes will come more frequently and eventually will become permanent. Then you are cured.

It is normal for the clarity of vision to fluctuate: clear, less clear, back to clear. Even persons with perfect sight experience times of less clear vision. When glasses are avoided, the vision returns to perfect clarity.

Q- If ones arms become tired while palming will a black silk handkerchief covering the eyes produce the same amount of relaxation one gets from palming?

A- No. Palming is the best method for relaxation and improvement in vision. When tired of palming, the hands can be removed and the eyes kept closed until one feels relaxed.

Q- My little daughter has temporary perfect sight while palming, but her eyes turn in when she plays excitedly or strenuously. I thought play was relaxing?

A - Play may be relaxing and should be beneficial, but like other things, it can be done wrong, necessitating great effort, and without benefit.

Q- I enjoy palming, but it makes me drowsy after ten or fifteen minutes. Is this helpful?

A - When palming is done properly it does not make you drowsy. It can be so relaxing that the person falls asleep if desired.

Q- I am presbyopic. How can I improve my vision?

A- By reading fine print and alternately remembering the whiteness of snow for a second while looking at the white spaces between the lines of print. Then close your eyes and remember or imagine the same white more continuously, better and more easily. By alternating, you may become able to remember the white as well when flashing the card as you can with your eyes closed, and your vision will be improved. Then, look at, see, read the letters clear.

## Announcements

Several back numbers of "Better eyesight," from 1919 to 1925, ordinarily listing at 30 cents per copy have been reduced to ten cents per copy. These numbers contain articles on cataract, glaucoma, myopia, hypermetropia, astigmatism, presbyopia, (old age sight), ect.

Those who wish to have their magazines from July, 1927, to June, 1928, inclusive, bound may have this done by sending in their magazines by July 15<sup>th</sup>. Any missing numbers will be supplied at 30 cents per copy. The charge for binding is \$1.00.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JULY, 1928

### Dark Glasses Are Injurious

He was a very intelligent chauffeur, and very polite and popular with most people. I enjoyed listening to his experiences in driving various types of cars. Nothing seemed to give him so much pleasure as to get into a "jam" and get out without suffering any injury to his own car or without tearing the "enemy" apart. The "enemy," as he explained, were the numerous other cars which were driven by chauffeurs who did not understand their business very well and who enjoyed teasing the inexperienced drivers.

One day we were driving to the seashore. The sun was very bright and the reflection of the light from the sun on the water was very strong and made most of the occupants of the car very uncomfortable. Personally I enjoyed the strong light of the sun. The chauffeur did not wear glasses for the protection of his eyes from the sun or dust and I asked him if he had ever worn them. He very promptly answered me by saying that he had worn them at one time, but discontinued wearing them because he found that after wearing them for a few days, his eyes became more sensitive to the light than they were before. He said he could not understand why it was that when he wore glasses to protect his eyes from the dust he accumulated more foreign bodies in his eyes than ever before. This seemed strange to the people in the car and they asked him to explain. It was decided that when the dust got into the eyes, the glasses prevented the dust from going out.

The eyes need the light of the sun. When the sun's rays are excluded from the eyes by dark glasses, the eyes become very sensitive to the sun when the glasses are removed.

Eye doctors sell sunglasses knowing it will lead to unclear vision, prescriptions for eyeglasses, eye surgery. Lack of sunlight causes cataracts and other eye problems.

## Fundamentals

By W. H. Bates, M.D.

**GLASSES DISCARDED PERMANENTLY:** Glasses should be discarded permanently because it is impossible to cure people by treatment without glasses when glasses are worn for long or short intervals of time. All cases of myopia (and presbyopia) are increased by the wearing of glasses. **If glasses are not worn, the vision of most people improves without other treatment.** Just removing glasses causes the eye muscles/eyes, brain to function natural, correct, return to clear vision - on their own, without knowledge and practice of Natural Eyesight Improvement.

(Modern teachers allow reduced/weaker eyeglass lenses if necessary for driving... they are worn as little as possible and discontinued when vision is clear enough to drive... safely. Vision improves much easier, faster when glasses are not worn.)

**CENTRAL FIXATION:** When the vision is best where the eyes are looking, and worse where the eyes are not looking, central fixation is evident. Central fixation when properly used is a relaxation and a benefit. It is interesting to observe that one cannot have perfect sight without central fixation. One should not strain and make an effort to obtain central fixation of a letter or any object, as by so doing, imperfect sight is very soon apparent. The normal eye shifts unconsciously from one part of an object to another, seeing the part regarded best and other parts worse, and the eye with imperfect sight must acquire this habit by practicing it consciously until it becomes an unconscious habit.

**FAVORABLE CONDITIONS:** There are many ways in which the vision may be improved by having the conditions or the environment favorable. There are many facts to be considered when discussing the most favorable conditions for the improvement of the sight without glasses. Some people see better in a bright light, while others see better in a dim light. The distance of print

from the eyes where seen best also varies with different people.

It is natural to suppose that to secure relaxation or rest the hours of sleep should be increased. While this may be perfectly true, it is difficult to harmonize the fact that increasing the hours of sleep does not always promote relaxation or rest of the eyes. Many people will retire with their eyes feeling perfectly comfortable, yet they may be awakened during the night by severe pain in their eyes. During sleep, eyestrain may be so severe or continuous that no rest is obtained for the nerves of the eyes or other parts of the body. (As I have stated in previous issues of this magazine, I have examined the eyes of patients with a retinoscope while they were asleep and have found the eyes to be under a great strain. Sleep, therefore, is not always a favorable condition for the improvement of the eyesight.)

The optimum distance or the distance at which the vision is at its best is widely variable. Some people may have normal vision at twenty feet but not at fifteen feet. Others are able to read fine print better at twelve inches than at six inches. By practice one can improve the vision so that it will be normal under all conditions.

**SHIFTING AND SWINGING:** When shifting is done properly, it is practiced easily, without effort or strain. When one shifts from a point to the left to a point to the right, the swing produced is continuous, regular, and promotes relaxation. It is possible to shift with the eyes closed with as much benefit as with the eyes open. There are some people who cannot shift with the eyes open without a strain and yet they can shift or swing or imagine perfect sight with the eyes closed.

Whenever the head and eyes are moved from side to side, one should imagine that stationary objects are moving in the opposite direction. This should be practiced at all times until the habit is obtained. (The various swings are described in the June and other issues of this magazine.)

**MEMORY AND IMAGINATION:** A perfect memory is a great benefit in obtaining perfect relaxation of the eyes as well as all the nerves of the body. One cannot remember a letter or other object perfectly unless it has been seen perfectly. When the memory is perfect, the imagination may also be perfect. Some people with a good imagination find it easier to imagine a letter or other object perfectly when they do not expend an effort in trying to see it. Knowing what the letter is, with the aid of the imagination, one becomes able to imagine that it is seen perfectly. (Familiar objects, Eyechart)

It is well to keep in mind that many patients believe that they see large letters perfectly when they do not and they can be tested by bringing the card up close to the eyes. The vision should be just as good at fifteen feet as it is at one foot. By improving the memory and imagination one improves the vision.

**REST:** Rest or relaxation of the nerves of the eyes, mind and all other parts of the body is necessary before perfect vision can be obtained. When the nerves of the body are at rest, it is possible to remember, imagine or see all letters or other objects perfectly. It is not possible to remember, imagine, or see anything without perfect relaxation. Perfect relaxation or rest comes without effort. When the mind is at rest, any effort to improve the memory, imagination or sight is wrong. (Use the memory, imagination in a easy, relaxed manner.) When the eye is at rest, it is perfectly passive. The eye at rest is never stationary: it is always moving. This seems a contradictory statement to make, but it is a fact which does not permit of any explanation.

**PALMING:** One of the best methods of obtaining relaxation is by palming. There is more than one way of palming. One very good way, however, is to cup both hands, press the sides of the palms together, and place the two hands over the closed eyes and in front of the nose. When done properly, all light is excluded, one sees black perfectly and relaxation is obtained.

**BLINKING:** When the normal eye is at rest, the eyelids are continually closing and opening. Blinking may be done so rapidly that it does not become conspicuous. Moving pictures (movies) have demonstrated that the normal eye may open and close, or blink, five times or more in one second. The habit of blinking may be acquired by remembering to blink at frequent intervals. All patients with 15 diopters or more of myopia may blink five times or more in one second when the eye becomes normal and myopic alternately five times in one second. There are no exceptions to this truth.

**MENTAL PICTURES:** The mind is capable of imagining all kinds of mental pictures. When the mind is at rest and the memory and imagination are perfect, all kinds of mental pictures are produced. When the mind is under a strain, the memory and imagination are imperfect and mental pictures are indistinct and cannot be remembered for any length of time. Central fixation when properly imagined is very helpful. With its aid a perfect mental picture may be obtained easily. When a mental picture is remembered easily and perfectly, the vision is benefited. Shift on the mental pictures. Imagine them as a movie, a motion, active picture in the mind.

It is a fundamental truth that when one letter of the Snellen test card is seen perfectly, all the letters of the Snellen test card can be seen perfectly. When the sight is perfect, a letter is remembered, imagined or seen as well with the eyes open as when the eyes are closed. The vision of one letter of the Snellen test card can be improved with the eyes open by practicing the memory or the perfect imagination of the same letter alternately with the eyes closed. Whatever is done to improve the memory of one letter is a great benefit, because all the other letters are improved at the same time. This truth can be demonstrated in all cases. There are no exceptions.

One patient who visited me recently was a girl of about fifteen years or age who announced that she would have to be cured that day because her parents would not allow her to spend any more time. By teaching her the fundamentals, this girl became able to improve her memory, imagination, and sight until she could read all the letters on the test card perfectly. **By remembering the first letter of each line perfectly, by imagining it perfectly, she became able to see it perfectly,** because with the help of the retinoscope she demonstrated that when she imagined the first letter on each line perfectly that her near-sightedness was cured temporarily. When the first letter of each line was seen perfectly, not only was the letter seen without any error of refraction, but she was able to read all the strange letters on each line with normal sight. She did not imagine the other letters; she actually saw them.

Shift left and right on the E and see it move in the opposite direction.  
+ Shift to the dot on the left, the E moves right.  
+ Shift to the dot on the right, the E moves left.

E

Palming

Palm and imagine black or any pleasant object, scene. Think happy thoughts. Shift on objects in the mind, see them clear, in color, motion.

Usually when persons have become able to read a familiar Snellen test card with normal vision and to read it continuously, they are able to read a strange card, and to read it just as perfectly as the familiar card.

A knowledge of the fundamentals which can be demonstrated during the process of the formation of **cataract** has suggested successful treatment. The most important fundamental to consider is that cataract always disappears when the memory or imagination are perfect.

Many cases of **opacity of the cornea** which have been preceded by diseases or ulceration are benefited or cured by an intelligent use of the fundamentals. The law of fundamentals has proved the fact that an imperfect memory will cause an opacity of the cornea. It is not too much to believe that conical cornea is caused by eyestrain. If this were true we would naturally expect that when the eyestrain was relieved that the conical cornea would be benefited. It is a good thing to know that "this is the truth."

Acute or chronic **glaucoma** in which increased tension is present has always been relieved by practicing the fundamentals as described above.

In the normal eye the tension of the eyeball is always normal. Tension can be produced by an imperfect memory and the tension can be lessened or corrected completely by the practice of a perfect memory, perfect imagination, and a perfect optical swing.

The encouraging thing about the fundamentals is that they are always true without any exceptions, that they always suggest successful treatment and that they always explain the cause of imperfect sight.

See Fundamentals, Better Eyesight Magazine July, 1927.

## An Artist Suffering From Presbyopia

By Emily C. Lierman

An artist, aged 61, who had for many years painted portraits of people who are well known in the West, suddenly became unable to go on with a painting which was almost completed.

Before I tested his vision with the test card or asked him any questions at all, he told me his story. As a boy, he began to paint landscapes and ships of all description and when his parents found that he was especially interested in painting, they encouraged him to make it a special study in school. Before he was twenty years of age he painted heads of young children, and the expressions of the faces as he painted them were so life-like that older and more experienced artists were anxious to have him do work for them. Later in life he came from England to California and there he has become well known because of his work.

I became acquainted with him through a cured patient of Dr. Bates who had some painting done by this artist. She had noticed that he was straining his eyes to see at the near point and that at times the work was not satisfactory to himself. He got into the bad habit of using a magnifying glass for the fine details of a certain painting he was doing. He told me that he had been seriously thinking about giving up the work that he loved so much, but his wife objected strongly to this because it made him melancholy and despondent.

He had worn glasses for twenty years and the four latter years he had tried bi-focals which were unsatisfactory. His oculist failed to help his double vision which interfered greatly with his work; he would see two brushes instead of one, and two objects where there was but one. Having become well known among the artists in the colony where he lived, it was not easy for him to decide what was best for him to do.

His eye test was, Right vision 15/40, Left vision 15/20. When he read the letters of the test card with his right eye, all of the letters appeared double – the large letters appeared double as well as the smaller ones. When he read with his left eye all the letters were clear.

I began treating him by improving the vision of both eyes together until he became able to read 15/15. Then we began to **work with the right eye while the left eye was covered with a black patch**. **Palming** helped him a great deal, so while he was under treatment he was encouraged to keep his eyes closed and covered with the palms of his hands for half an hour or longer each time. I again tested his right eye with the test card. The double vision still continued, even though the vision had improved in that eye.

I directed him to palm for a longer time and to get a **mental picture of a painting** he had been working on recently. I improved his vision during his first treatment to 15/10 with the right eye as well as with the left and the double vision temporarily disappeared. Mental pictures of the work that he loved to do relaxed his mind and he himself realized that it was the strain that produced the double vision and that **he had been using his right eye more than the left**.

How many people are there in this world who know that they are really using their eyes correctly? I fear that there are many who do the same as my patient did in **unconsciously using one eye more than the other**; that is to say, **he strained more with one eye than he did with the other**. See 'switching close and far, both eyes, one eye at a time, both eyes together again' for perfect, equally clear, balanced vision in the left and right eyes at all distances in the Book: Do It Yourself – Natural Eyesight Improvement. If I can make myself more clear to those who are interested in this article by explaining how double vision can be produced consciously, as well as unconsciously, I should like to do so as follows: If one will press the lower lid of the eye with the forefinger, while both eyes are open, one can immediately produce two objects where there is only one. The harder the pressure against the lower lid, the further away the one object moves from the other. One is real and the other is, of course, an illusion.

I believe that it is a good thing to practice this consciously where one is troubled with double vision. When the double vision becomes worse consciously, one is very apt to become able to cure this error sooner than is expected. One can imagine how my patient must have strained his right eye in order to produce the double vision constantly, not only while he was at work but at all times while he was awake. (Tense outer eye muscle placing pressure on the eye.)

I had a pair of discarded glasses in my office which were left by a cured patient who gave them to me as a souvenir. I used a paper to cover the lens of the left eye and removed the glass entirely from the right. In this way my patient was able to practice for a length of time with the right eye without having to use his hand to keep the other eye covered. (Holding the hand up leads to tension in the arm, shoulder, neck, back, eye muscles. Use a eye-patch.)

Practice shifting, central fixation, switching close and far, memory, imagination... with both eyes, then one eye at a time (eye not in use covered by patch). Practice a little more with the eye that needs vision, movement improvement. End by practicing with both eyes together again.

Switch the visual attention back and forth on two identical eye charts placed at two different distances.  
 + Shift on a letter on the close card in the hand.  
 + Then shift on the identical letter on the chart at 1 foot.  
 + Shift on the letter on the close card again. Repeat.  
 + Practice on other and smaller letters.  
 + Practice with the distant card at other distances.  
 + Practice with both eyes together, then one eye at a time, (spend extra time with the eye that needs vision improvement). Last; practice with both eyes together again.

I placed a large test card on the back of a chair which I located about a foot away from the patient's eyes. I then gave him a small test card to hold in his hand. (The letters of the small test card were similar to those on the card which was on the chair.) The patient was directed to look at a letter of the test card in his hand and then shift to the same letter on the card a foot away. By doing this he avoided staring. When shifting is done correctly, not only is the vision improved, but one is relieved of strain in all other parts of the body. The patient practiced the above for more than half an hour with the result that during the next half hour we were able to improve his distant vision and he did not see double.

I was not so sure about the patient being able to continue the treatment at home by himself, so I advised him to come again a week later. When I saw him again, he said that he had noticed a decided improvement in distant objects while driving his car, and also for near work such as reading his correspondence, but when he tried to do a little painting, he did not find the shifting so easy, and because of that he could not avoid the double vision at that time. I was pleased to hear that he had improved to some extent and that it was only left for me to solve his problem of avoiding double vision while at his work.

During this lesson I described a way to shift from a letter that he was writing to a small test card which was placed on the desk to the left of him. He glanced at any letter that came within his line of vision, remembered the letter, and looking back to his pen and paper he was able to continue writing for a while without knowing that he had eyes. But going back to the work which meant fine details and getting them accurate had caused the same kind of strain which produced double vision.

I had him try the following: I tore a test card in half and by making a hole in it made it similar to a palette. He held the card in his hand blank side up and on it were placed letters and numerals in different places. He was told to imagine that the numeral which was placed in the upper right-hand corner of the card was a certain color to be used for the painting. He was to place the right hand under the numeral and then point to the card with his right hand. Then again he placed his finger on a letter which was placed on the lower left-hand corner of the card and then shifted to a card about a foot away, always pointing to the duplicate of the letter on the card in his hand.

While practicing in the above way he did not once complain of double vision, so he was advised to try this method at home and to write me within a few days, giving me a report of the progress he was making. He could not wait a few days, so he wired the next day telling me that he was successful in shifting from the palette and paint that he was using to the canvas and to do it in an easy way, without effort or strain and by doing so, for the first time in a long while he did not see double while at work.

I helped him a great deal by advising him by mail. For a while I did not hear from him and finally one day, I received a telephone message from him. He was at the home of one of the subjects whose portrait he was painting. This man was seated in a wing chair with his one arm placed over the side of the chair. My patient stated that his vision blurred as he tried to finish the details of this painting. The harder he tried to relax and to remember some of the things I had told him to do, the worse his vision became.

I asked him to start swaying his body slightly from side to side and to imagine that the telephone was moving in the opposite direction to the way in which his body was moving. He said that he could do that very well and that when he blinked while he was swaying it was restful. I told him to keep this up for about five minutes or longer and then to go back to his subject, and imagine that he was moving his body from side to side as he did while he was talking to me over the telephone.

I told him that I would be in my office for the rest of the day, but the arrangement was made that if he had no more trouble in completing this painting that I would not hear from him again that day. He did not call again. Sometime later he wrote me a letter, telling me that for the first time he had noticed that some of our test cards had imperfections which he explained to me in detail. Dr. Bates and I had noticed the mistakes in the printing of some of the cards, but it was seldom that the patients had noticed these small defects. It pleased me very much that his sight should improve to such an extent that he was able to detect these mistakes.

Another method which I used during his treatment has also helped others in their particular line of work. I gave him a small test card with the Fundamentals on the reverse side and asked him to hold it where he could see the print best. He said that he could not see it well at any distance, but if he held the card at arm's length, he could read the Fundamentals up to Number 6, without the sentence appearing double to him. He thought he had made a fine discovery when he found that he could read to sentence Number 3 by squeezing his eyelids together. I gave him a hand mirror and asked him to look at himself while he squeezed his lids together, and asked him if he thought it would look well for him to go through life reading in that way.

The strange part of it was that he did not squint very long while he was looking in the hand mirror, because, he said, he did not like the expression of his face.

I placed him at my desk with the hand mirror in front of him, about two feet away. I gave him the Fundamental card to hold and told him to shift from the white spaces of the type to the mirror and to look at his eyes each time he looked in that direction. He said that shifting from the narrow white spaces of the Fundamental card to the mirror helped to avoid the double vision at that time, so I told him to practice it. By alternately palming and shifting from the microscopic type to the Fundamental card type, he became able to read the finest print on the card at six inches without double vision.

## Questions And Answers

Q - Some days I can read the Snellen test card to the 15 line, while at other times only to the 30 or 20. Why?

A - When the eyestrain is less the vision is always better.

Q - While palming is it necessary to close the eyes?

A - Yes.

Q - Are floating specks serious? Sometimes they just flood my eyes like clouds of dust and greatly frighten me.

A - Floating specks are not serious. They are always imagined and never seen.

Q - By following instructions in the book, can cataract be benefited without consulting a physician?

A - Cataract has been benefited by following the instructions in my book without consulting a physician.

Q - I find conscious blinking a strain, because I close my eyes temporarily and seem to hold the eyeball stationary. If I shut my eyes for a longer period would that be blinking?

A - No; the normal eye blinks consciously or unconsciously without effort, without strain, and does it quickly.

Q - If the sun and light are beneficial, why do you advocate the shutting out of these two by palming?

A - To obtain relaxation. The sun strengthens the eyes and palming rests them.

Q - Why, after palming for ten minutes or longer and my eyes are rested, do I feel sleepy?

A - The palming is not perfect. Try imagining stationary objects to be moving when you palm.

Q - When I read and blink consciously, I lose my place. Why?

Q - This is caused by strain, which prevents one from remembering the location of letters.

Q - Explain what you mean when you say "imperfect sight, imperfect memory."

A - If you see an object imperfectly, blurred or gray instead of black, you cannot remember it perfectly. You will remember it as you see it.

Q - If there a possibility of palming wrong? I can obtain some benefit, but later I feel strained.

Q - Palming may be done properly or it may be done wrong. I would suggest that you read the chapter on palming in my book.

Q - I get nervous if I palm for any longer than ten minutes at a time. Can I obtain as much benefit by palming for short periods at more frequent intervals?

A - Yes.

Q - What is the circular swing and how is it practiced?

A - The circular swing is described in the June number of "Better Eyesight."

## Announcement

Several back numbers of "Better Eyesight" from 1919 to 1925, ordinarily listing at 30 cents per copy have been reduced to 10 cents per copy. These numbers contain articles on cataract, glaucoma, myopia, hypermetropia, astigmatism, presbyopia (old age sight), ect.

## SCHOOL NUMBER BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

AUGUST, 1928

## Suggestions

It is recommended by the editor of this magazine that every family should obtain a Snellen test card and place it on the wall of some room where it can be seen and read every day by all the members of the family. Not only does the daily reading of the card help the sight of children, but it is a benefit to the eyes of adults as well.

Presbyopia Cure

It is a well known fact that when most people arrive at the age of forty or fifty years, they find that their vision for reading or sewing is lowered. These people believe that they must put on glasses to prevent eyestrain, cataract, glaucoma, et cetera. Daily practice with the Snellen test card, together with the reading of fine print close to the eyes will overcome their difficulty. Reading fine print close to the eyes, contrary to the belief of many ophthalmologists, is a benefit to the eyes of both children and adults.

It had been repeatedly demonstrated, however, that fine print cannot be read clearly or easily when an effort is made.

The following paragraph refers to a person with blurred vision making a effort, strain to see black letters;

When the eyes look directly at the letters, an (unnecessary) effort is required (made), while looking at the white spaces between the lines is a rest, (because there is nothing there to see, so the person avoids effort, strain.) and by practice in this way, one can become able to see the letters clearly, without looking directly at them. When a patient looks at the white spaces between the lines of ordinary book type, (occasionally to rest the eyes) he can (then, look at the black print) read for hours and no fatigue, pain or discomfort is felt.

When discomfort and pain in the eyes is felt while reading, it is because the patient is looking directly at the letters: (with an effort, without central fixation, without movement/shifting, blinking, relaxation).

The above paragraph is an old technique containing some steps that are no longer used. The blue print is added by Clark Night to clarify this.

Looking at the white spaces does relax the eyes, produces clear vision, but, trying to see the black print while looking at the white spaces causes the mind/eyes to attempt to think about/see two different things, the central and peripheral fields at the same time. This is diffusion, eccentric fixation, prevents central fixation, leads to strain, tension, blur.

It is ok to look at the white spaces to relax the eyes, mind, to remember, imagine the white spaces pure, bright white to improve the memory, imagination, clarity of the space, but; when reading, look directly at the print, shift/move the eyes along the sentence.

Read through the 'center of the words' or, just let the eyes shift about the letters, words as the eyes move on/along the sentence.

Looking directly at the letters will not cause strain, effort if relaxation, central fixation, movement/shifting are applied.

The eyes can look directly at the letters, relax and see them clear.

Looking at the white spaces also relaxes the eyes, and when the person then moves/shifts from the white spaces to the black print, relaxation continues and the print is seen/read clear.

Always read the print by looking at the print, not the white spaces.

When looking at the white spaces - avoid staring: shift on the spaces to prevent staring and to produce relaxation, clear vision.

## School Children

By W. H. Bates, M.D.

About fifteen years ago, before the medical society of Greater New York, I read a paper on the prevention and cure of imperfect sight in school children, illustrated with stereopticon pictures. Physicians who attended were very much interested in what I had to say. In the course of my reading I mentioned that most books on ophthalmology have published the statement that near-sightedness was made worse by an effort or strain to read at less than six inches or to read in a dim light. I went on to say that a careful study of the facts demonstrated that much reading in a dim light at the near point will not produce near-sightedness in school children, but will produce the opposite condition far-sightedness. (far-sightedness occurs only if strain, effort is allowed when reading the print) A great many members rose up immediately to disprove this statement. They were unable favorably to impress those present because not one of them had investigated the subject. They admitted that they condemned such statements because most German physicians and many French, Italian and others had, like them, condemned the methods employed from hearsay and not from actual investigation or experience.

It was a rule of the society that every paper should not require more than twenty inches for its reading. After more than half an hour had passed I asked the president of the society how much more time I could have for finishing my paper. He answered that as much time would be allowed for finishing the paper as was necessary. The answer was so encouraging that nearly two hours elapsed before I was finished. The meeting was then thrown open for discussion and many of the ophthalmologists present publicly stated that near-sightedness, far-sightedness, astigmatism, cataract, glaucoma and many other eye diseases could not be cured by operation or by the use of drops or other local eye treatment.

Those present asked many questions and the answers satisfied some and annoyed others. One question was asked which would have required some hours before it could be answered intelligently. It was as follows: "What percentage of cases of myopia in school children can be cured or prevented without treatment?" I answered that statistics were misleading. Someone has said that one can prove anything by statistics, but I disagree with him.

About midnight, the janitor appeared on the scene and whispered in the ear of the president a message which must have been annoying from the way the president acted when he received it. The president then said that the paper was so valuable that its discussion must not be curtailed, and if the janitor expected the society to adjourn, the members would go downstairs to one of the large rooms which was not occupied. It seemed to me as though all the members passed on to the new room.

A few weeks later another paper on myopia was read by invitation before the medical society of the County of New York. Among other things, I said that if it could be demonstrated that one child of the Public Schools of the City of New York did not produce or acquire myopia by an effort to see at the distance that I was wrong about the whole matter. The Board of Education heard of this statement and became interested. They sent for me to appear before them. I visited the Board of Education and told them about my investigations and offered to introduce the method in the schools for the prevention of myopia in school children. Some of the members of the Board themselves demonstrated that when they made an effort to see at the distance that the sight became less from the production of myopia, and that rest lessened the myopia. Much to my surprise it was voted that my methods should be given a trial in the public schools of the City of New York.

Soon afterwards I called on the principal of one of the schools and asked for an opportunity to prove that I was right. The principal listened to my story and when I had finished said to me: "Come with me and we will try to prove whether you are right or wrong."

She invited me to one of the school rooms where a number of the children were suffering from eyestrain or were wearing glasses. When their glasses were removed their vision was imperfect. While their glasses were removed they were asked to sit with their eyes closed. At the end of fifteen minutes the sight was tested and all were found to have improved sight. Some had even obtained normal vision. The principal then said to me: "Remain here, doctor, until I return."

She then went to one of the other classrooms. In a little while she returned smiling. She said: "Doctor, you are right; rest of the eyes does improve the imperfect sight of myopia. I am pleased to inform you that I was able to cure about a dozen children just by having them close their eyes and resting them for some minutes. I would like to have you meet some of my teachers and explain your method to them for their benefit." I found out later that she treated these children privately herself so that she could be sure that magic was not used.

### Memory, Imagination, Relaxation and Vision Function Together

In the beginning it was demonstrated that the memory played an important part on the cause, prevention and cure of imperfect sight in school children. It was also observed that improving the imagination enabled the children to improve their sight. They soon learned that they could only see what they imagined and that they could **imagine what they remembered, and remember only what they saw.**

A number of children were found wearing glasses who were backward in their studies and complained of attacks of headache and pain in their eyes; they were restless and took very little interest in their studies. After eye education was practiced, not only did the vision improve, but the mentality as well.

Teachers in other cities also used my method of eye education in their classrooms. A teacher in the West devoted considerable time to teaching children how to remember, how to imagine, and how to see by using their eyes without effort or strain. She taught them how to palm until their eyes were rested. She had the whole class stand up and sway from side to side and imagine stationary objects to be moving.

Her efforts to improve the imagination of the children were most interesting. One method was to have the child close the eyes and draw some fantastic and unusual figures of people, animals and other objects while the eyes were closed. Some of these drawings were so valuable and interesting that they were used by older patients to improve their imagination. Many weary hours of work were relieved by having the children practice relaxation methods. In time the children enjoyed these relaxation methods and practiced them at recess. **One child who was able to improve his sight very promptly enjoyed teaching other children how to improve their sight.**

### Children are Often the Best, Perfectly Natural Vision Improvement Teachers

The Superintendent of the Public Schools in North Bergen, N. J., published in this magazine in August 1925, a report of the result of the adoption of my methods in his schools. In many of the schools were children 16 years of age in the same class as other children much younger. One very important result of the practice of relaxation methods in his schools was that children suffering

from retardation were materially benefited or cured so that their teachers were able to place them in the classes in which they belonged according to their years.

After my methods were practiced in the Public Schools of New York for several years with great benefit, some physicians interested in eye work believed that the eyes of the children were not benefited by eye education and through their recommendation the practice of my method was stopped. I cannot understand why the Board of Education was willing to abandon methods which were practiced by teachers who were much pleased with the results obtained, in favor of methods which had failed to bring about any material benefit. (Optical industry hiding Bates Method from the public.)

## School Children

By Emily C. Llerman

Squint and Blur

During the spring of last year I had a class of boys under treatment. There were twelve in this group and each one had to be treated individually in order to improve his vision permanently. Two of them were brothers. The younger of the two, age nine, had normal vision in the right eye or 10/10 and he read all the various test cards I had without effort or strain. The vision in his left eye was also 10/10 but while reading the cards, while his right eye was covered, he held his head to one side and strained to see each letter. When he read the letters with both eyes together his left eye turned in considerably. His mother, who had been treated by me, was much concerned about the possibility of this condition becoming worse.

While he kept his right eye covered, I placed him fifteen feet from the cards and at this distance, with some effort, he read 15/30 and he complained that the letters were blurred. Palming seemed to help and I noticed that while his eyes were closed he sat quietly in his chair. At other times he was nervous and never still for a moment.

While he was palming, I talked about animals and their habits, how they moved about without any effort on their part—especially how the deer, cow, and even the bulky elephant could move about without any effort. Blinking their eyes was something they knew nothing about, yet they blinked all the time which helped them to keep relaxed always. The deer only strained and showed signs of fear when danger was near. The cow not only blinks but chews a cud and this keeps her busy and at the same time relaxed.

**The elephant sways his body when he is quiet and relaxed. Even when he walks his head and body move up and down.** (The sway, the Long Swing.) Elephants live many years longer as a rule than any human being and I sometimes wonder if they would live so long if they suffered eyestrain like human beings.

My boy patient listened as I explained all this to him and it certainly helped. I only saw him four times and during his last treatment his left eye remained straight just like the right and his vision with each eye improved to 20/10. He practiced faithfully every day for more than two hours, alternately swinging, palming, and consciously blinking his eyes as he looked from the first letter to the last letter of a line on his test card. At other times while swaying his body from left to right he would look at a picture on the wall to the right and then to another on the left wall, always blinking, keeping time with the swaying of his body.

### Eyes Sensitive to Sunlight and Sunlight Treatment

His elder brother had no trouble in reading his books or seeing letters or figures on the blackboard at school, but when he joined his schoolmates at baseball, basketball or any other game, including golf, his eyes pained him so much that he had to squint his eyes continuously while he was in the sun and he sometimes became blinded by the sun for a half hour or longer. This of course, alarmed his parents.

This boy needed sun treatment and as I was teaching this class of boys in the evening, I used electric light for the treatment instead. A 350-watt electric light was adjusted to a floor lamp which was arranged without a shade so that with the sun glass I could focus the light directly on his closed eyelids. Previous to placing the bulb in position I had directed the boy to keep his eyes closed so that he would not know what I was going to do next. If he had watched me adjusting the light he would have strained as he faced it. I explained to him that if he would keep his eyes closed I would give him some light treatment, which would be of benefit not only to his eyes but in other ways.

(Artificial light is partial spectrum, not as healthy as full spectrum sunlight but is better than no light.)

Before I gave him the light treatment he told me how difficult it was for him to read in the sunlight or with an ordinary electric light without squinting and wrinkling his forehead and distorting his face. I placed a book near him, which was given to him after the light treatment, and we had good results instantaneously. There were others in the room besides my class of boys who were interested in this particular case. They watched closely as the boy held the book eight inches from his eyes and read distinctly without any signs of effort or strain.

Sway left and right. Blink.  
Sway right and look at a picture on the wall, to the right.  
Sway left, look at a picture on the wall to the left.  
Shift relaxed, easy on objects in the pictures without trying to see clear, without stopping the sway.

Sunbathing - Face the sun with eyes closed. Move the head side to side. Do the sway. Relax the neck, head, eyes, body.  
Go outside daily in the sunlight without eyeglasses, contacts sunglasses and look at objects at ground level, then tree tops, clouds... (Do not stare into the sun. Look at the bright sky.)  
Seek shade under a tree as needed to avoid sunburn.

Baseball

Palming

The boy palms and remembers, imagines playing baseball, his favorite sport. Imagines shifting on the ball, seeing its size, color, motion, sees it clear, imagines pitching, hitting the ball, running the bases. Remembering, imagining a favorite subject, hobby, object relaxes the mind, body, eyes and improves the vision.

Math

A girl likes arithmetic. She palms and relaxes her mind, eyes by imagining, remembering numbers, easily seeing numbers clear in the mind and adding the numbers correctly. The mind relaxes, the memory, mental pictures improve when thinking about a favorite, happy subject. This prevents mental, visual strain and improves the vision. Mental strain, imperfect memory, worry, thinking unhappy, boring thoughts causes strain, tension in the mind, body, eyes, eye muscles and unclear vision.

The boy's mother made an appointment with me for the next day and an hour's treatment was given him in the bright sunlight. Two treatments were all that were necessary to give him permanent relief and he had no more discomfort or signs of strain or tension while he played basketball or baseball with the rest of the boys.

Another one of this group had **irritated eyelids**, the appearance of which was worse than the discomfort or pain that the boy experienced. He blinked more rapidly than the normal eye does unconsciously. Sun treatment was given to him also. When the mother saw that he had obtained a noticeable amount of relief from the first treatment, she purchased a **sunglass** and under my supervision she learned how to **use the glass on his closed eyelids** and in this way all he needed was the one treatment.

The rest of the boys in my class were soon relieved of their eyestrain, which was due to straining while reading at the near point and trying hard to see objects at the distance. By shifting from the white space between two lines of microscope type and looking at a test card placed ten feet from where they were sitting and then at a test card placed twenty feet away, they were relieved during the one treatment. It was not easy to make them understand that it was not a game that I was playing, but I became as one of them because it is the only way that I can be successful in my work. It is always good while treating boys of their age to be interested in their work or in those things which interest them especially.

As I explained in previous articles it does not take long for a boy who is interested in baseball to obtain normal vision if it is only near-sightedness or far-sightedness which troubles him. While they are palming they can always imagine the size of a baseball and the color of it. They can always imagine that they are pitching the ball and that they are running to first, second and third base. In this way **their minds become relaxed during the palming period** or while their eyes are closed without being covered with the palms of their hands. This method always improves their vision for the test card and for big type.

With girls who are of school age, I find out, while they have their eyes closed and covered, what special study they like best. If it is arithmetic, for example, I have them give me an example and purposely I make a mistake in answering, which they correct. In their minds they are doing the example correctly and **their minds become relaxed because there is no cause for strain**. I have tried having a child do an example when arithmetic is not a favorite study with her, and I have not at any time found such a child who could get the answer correctly within a reasonable length of time because I produced mind strain, which in turn produced eyestrain and imperfect vision. This demonstrates that Dr. Bates is again right in saying that when the mind is under a strain, the eyes cannot have normal vision.

+Mind strain = imperfect memory, imagination, eye muscles tense - abnormal eye shape - incorrect focus of light rays in the eye - brain not function correct with light, eyes, retina, eye muscles, nerves = unclear vision.

+Mind relaxed = memory and imagination perfect, eye muscles relaxed, function correct - normal eye shape - correct focus of light rays on retina, brain functions correct with incoming light, eyes, retina, eye muscles, nerves = clear vision.

## Case Report

### Military Story

#### Man Experiences Blindness - How He Returned to Clear Vision

By Joseph Oulmet

So many are the testimonial letters from satisfied clients that are published by manufacturers of specifics in newspapers and magazines, who pay so much per line for their insertion, that this means for expressing one's appreciation has been abused and discredited to such an extent that when a client desires to show his gratitude for a certain and specific cure, he is in danger of being disbelieved.

Nevertheless, at such a risk, I shall relate my own experience during a period of utter darkness, during which time the light did not penetrate into my eyes. In my soul reposed uncertainty, due to the assurance of a doctor that I would never recover my eyesight. Those were times of sorrow very difficult to forget, and now that light once again penetrates into my eyes, showing me the greatness of a world full of colors and infinite harmony, it is my desire to express in these few lines my appreciation to the man who brought me out of the world of darkness. I also wish that my experience may serve as a guide to all those who are endeavoring in vain, through erroneous means, to regain their eyesight or who have resigned themselves to live in a world of total darkness, after trying of trying out experiments without results.

To begin my story, it is necessary that we go back to the year 1917. At this time, from all cities of the United States, men in the prime of life were leaving for Europe, some never to return but to remain on the battlefields of France as a testimony of the heroism and sacrifice of a nation who willingly sent millions of soldiers to fight for a principle.

I was one of the many who, from the shadows of night to daylight, was converted from a peaceful citizen to a war soldier and who received the baptism of fire on French soil. There I slept in muddy trenches, suffered hunger and cold, fought in defense of my life. One afternoon while repelling a counter-attack, I was enveloped in a cloud of poison gases. Tears came to my eyes, which were inflamed to such an extent that I was unable to distinguish the objects which were located two feet in front of me. In despair I rubbed my eyes with my hands and almost crazy with pain I started to run without knowing where, until I stumbled and fell, a blow mercifully relieving me of all pain and making me lose consciousness.

Upon regaining my senses, I found myself in a hospital bed, where started many tedious and ineffective treatments designed to bring me out of the world of darkness to which the poison gases had doomed me. Days like a long endless night passed in the hospital, during which my eyes endeavored to form images and visions of things that in former times were so pleasing to my eyes. Only within my soul and as memories, such images took shape as though it were a new irony of life looking with delight at my loneliness and showing me the treasures that I had lost.

One day the doctor under whose care I was, being tired of making trials and seeing that his efforts were in vain, gave me up as incurable. When I was so informed, when the doctor's words shattered the only rays of hope that I still had, it seemed as though the world was sinking from under my feet. It seemed as though the world had come to an end as far as I was concerned. I had no further hopes or ambitions, but resigned myself to my fate and to wait for death to visit me as soon as possible so that I might take my trip to the infinite.

I thus returned to my native land, discouraged at heart, without being able to see anything, not even the ocean that was murmuring under me, nor the sun that shone upon my body, nor the faces of my comrades who happily commented about the proximity to their happy homes. When the boat sirens, the jubilant screams of my comrades; when the distant voices of the multitude who were anxiously awaiting the arrival of the steamer, made me aware of our arrival at the port of debarkation, I

experienced the most bitter moments of my life, especially when, at the dock, with eyes filled with tears I embraced my dear beloved ones, holding them strongly in my arms, so as to behold with my sense of feeling those whom my eyes could not see.

Then, little by little, by resigning to my fate I was able to drive out bitterness from my soul, until one day I was told about the Clinic of Dr. W. H. Bates, which I visited for the purpose of simply trying out one more cure but without having hopes of any kind. A few days after visiting the clinic and without receiving any other treatment but **sun baths** and **relaxation treatment** under the electric light, I observed a rare change. It seemed to me as though the darkness were becoming less dense and at times it seemed to me that I could see small objects which would appear from time to time, to disappear again rapidly, until one day a miracle took place.

A ray of light penetrated my eyes; it was like a shadow which I could distinguish vaguely in the shape of a bundle, without being able to determine exactly what it was. Although I could see so very little, my soul was filled with joy. From then on I dismissed from my mind all lack of confidence, and practicing faithfully the methods recommended, the bundles that my eyes vaguely could make out, gradually took a shape of reality until I was able to distinguish objects in their true form. Once again a return to life after having been for several years in the worst of all human jails and now that my sufferings have come to an end almost entirely, I am in a very good position to appreciate this treasure that God has given us so that we may behold the infinite wonders of his creation.

I wish that my knowledge were more extensive so as to describe in detail the methods that Doctor Bates employs in his clinic so as to bring about similar miracles, details which although very simple, inasmuch as the methods are not tedious nor difficult, involve certain technicalities which only through the lips of a man of science can be made sufficiently clear for the layman to understand in all its details. It is not the technician who is writing these few lines but a grateful person who desires to pay with the only available means for a good service.

The results in my case I do not hesitate to call miraculous, in view of the fact that I had been considered as incurable by other doctors who, by using antiquated methods, made me lose time and money, and endure years of suffering. In view of these circumstances, any praise that I may give Dr. Bates, will not be enough and if I have refrained from using more appealing terms in my narrative, it is because I would not want my sincerity and good faith to be doubted in any way. Should it be necessary, I have not only one witness but several, as well as friends, acquaintances and persons of reliability who have known me for a long time and who would not hesitate to corroborate every word of my statement.

Today my satisfaction is complete on account of being almost entirely cured, and I think that in this world there must be many unfortunate ones who, not being as fortunate as I, have been unable to obtain relief from such a terrible malady. How much would I like to have this message reach their hands! Were I one of the sons of fortune who from birth has been showered with wealth, I would be glad to devote part of my money so that everyone who may have any eye affliction may receive these good tidings, but inasmuch as my limited resources do not permit me this pleasure, I hope that these few lines will serve as a sincere testimony of one who is very thankful for the services obtained in the Clinic of Doctor Bates.

There is a movie telling the true story of a man blind since childhood from cataract and retinitis pigmentosa. When he was a adult he had a cataract operation and regained his sight. After about one year he became blind again. None of the doctors treated him with the Bates method which could have cured the cataract and retinitis pigmentosa without operation. They did not teach him how to use the memory and imagination to learn to identify objects and get his eyes working with the brain. His eyes, brain had not seen anything for years, he had very few mental pictures so all objects when first seen were unfamiliar. This was very frightening, confusing for him. Imagine never seeing a car, street, house...

If the Bates Method would have been applied the man may have obtained clear vision naturally and maintained the vision.

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

SEPTEMBER, 1928

### Eyestrain

The eyes of all people with imperfect sight are under a strain. This is a truth. Most people believe that during sleep the eyes are at rest and that it is impossible to strain the eyes while sound asleep. This, however, is not true. Persons who have good sight in the daytime under favorable conditions may strain their eyes during sleep. Many people awake in the morning suffering pain in the eyes or head, neck. Often the eyes are very much fatigued and have a feeling of discomfort.

There may be also a feeling of nervous tension from the eyestrain, or there may be a feeling as of sand in the eyes. At times all parts of the eye may be suffering from inflammation. The vision is sometimes lowered for several hours whereupon it begins to improve until it becomes as good as it was before the person retired the night before. Many people become alarmed and seek the services of some eye doctor. Usually the doctor or doctors consulted prescribe glasses which very rarely give more than imperfect or temporary relief.

There are various methods of correcting eyestrain occurring during sleep. **Palming** is very helpful even when practiced for a short time. A half an hour is often sufficient to relieve most if not all of the symptoms. In some cases the **long swing**, practiced before retiring, is sufficient to bring about temporary or permanent benefit. **Blinking** and **shifting** are also helpful. Good results have been obtained by practicing a **perfect memory or imagination of one small letter of the Snellen test card alternately with the eyes open and closed**. A number of patients were benefited and usually cured by **remembering pleasant things perfectly**.

## Aviators' Eyes

By W. H. Bates, M.D.

Military, Pilots

**AVIATION** is becoming more popular than ever before. The writer has treated many aviators who had, within a few months, acquired trouble with their eyes which made it dangerous for them to continue to fly. During the war a Major, an Aviator in the Army, consulted me about his eyes. His principle trouble was **dizziness**. He was wearing glasses for the correction of a slight **astigmatism**. The glasses did not relieve the dizziness. At this time a large number of aviators had been killed by falls.

The history of this aviator was very interesting and valuable. He was positive that a number of years previously when he began to practice flying that his sight was normal - 20/20 with each eye or with both. After a few years he noticed that his sight was impaired and that he had attacks of dizziness which did not last long in the beginning. These attacks of dizziness would come without warning while he was flying about one thousand or more feet above the ground. While he was conscious of the dizziness, he noted that his machine (plane) started to fall and continued falling until the dizziness stopped. It was some months before he realized that with every attack of dizziness the machine fell a greater distance, and he feared that these spells would ultimately cause his death.

Like most Army and Navy men, the Major did as he was told and was cured by me. This is the way it was done. I tested his eyes with the ophthalmoscope and retinoscope and found no disease of his eyes. The retinoscope revealed a small amount of astigmatism in each eye. His vision for the test card was 20/30. When he closed his eyes and rested them, the astigmatism became less and his sight for the test card became normal - 20/20. This was accomplished in about an hour. The improvement was only temporary, however, and he was given advice for treatment at home. A large test card was given him with directions to read it with each eye separately at twenty feet. He was directed to rest his eyes often by closing them. It was suggested to him that he look at one letter which he remembered better with his eyes closed than he imagined or saw it with his eyes open. By repetition, his vision for the known letter improved and his sight for unknown letters and other objects improved until his vision became 25/10. He was under treatment for about a month and he was seen at irregular intervals during that time. Since that time I have not heard from him personally.

Other aviators have been benefited by the same treatment. There is a right way and there is a wrong way to use the eyes when controlling a flying machine. The time required to do the wrong thing is just as long as the time required to do the right thing. The aviator can also demonstrate that an imperfect memory, imagination or sight is more difficult than a perfect memory, imagination or sight.

For example, a small letter "o" can be remembered imperfectly on one of the lines of small letters of the Snellen test card, (this will cause strain, blur) but a stare or strain to see it with a white center as white as snow may require much effort, time and trouble. (this will also cause strain, blur) The imperfect whiteness of the letter soon disappears while its blackness turns to a shade of dark or light gray, all covered by a blurred cloud. The concentration, the effort to see, brings on discomfort, fatigue, pain, dizziness and other nervous symptoms which are all difficult to remember, imagine or feel. **The memory, imagination or sight can only be demonstrated easily when exercised without strain.** The successful pilot when at his best is always doing the right thing.

When riding in a fast moving train, the telegraph poles, although fastened to the ground, appear to move in the opposite direction. But any effort to stop this movement brings on a strain which may cause much pain, dizziness, fatigue or other nervous discomfort. The Major, who recognized the bad effects of dizziness from imperfect sight, believed that the dizziness, if sufficient, could cause fatal accidents when flying. He became able consciously to produce dizziness by eyestrain or by an effort to improve his vision.

He was taught to imagine the floor to be moving when he walked about his rooms. Swaying his head and eyes from side to side enabled him to imagine the floor to be always moving. When he steered his plane to the right, all objects seen appeared to move to the left. When he moved to the left all objects seen appeared to move to the right. He was able to lengthen the apparent movement of stationary objects. The wider the movement, the less was the sight improved, while a shorter movement of the eyes or head was followed by a greater improvement.

It was difficult for him to demonstrate that perfect sight can only be obtained by rest and prevented by an effort. But when he had learned that it was a truth without an exception he soon became able to demonstrate the facts. He was encouraged to improve his vision by using various or all parts of his machine as objects for testing and improving his sight. The more successful he was in improving his memory for objects, the better was the vision. **We can only remember perfectly what we see perfectly; we can only imagine perfectly what we remember perfectly; we can only see perfectly what we imagine perfectly.**

The time required for a cure varies with individuals. The eyes of some aviators may be under a greater strain than that of others.

The aviator should demonstrate that shifting the eyes or moving the eyes from one small part of his plane to other objects is restful and that his sight is always improved by resting his eyes. Blinking or closing the eyes and opening them quickly is also a rest. He should also demonstrate that closing the eyes for a few seconds or longer and then opening them for a shorter time is a benefit to the sight. Palming or covering the closed eyes with the palm of one or both hands when done right always improves the vision. **Blinking, shifting, or palming can be practiced before entering the plane and so accidents may often be avoided.**

While attacks of dizziness are a frequent cause of accidents, many of them fatal, there are numerous other causes which are just as serious or important. Many fliers of airplanes seldom have accidents. What is the secret of their success? It is due to their control at all times in all places. Control of what?

The answer is: Control of the mind, control of the eyes and of all the nerves generally.

When the efficiency of the mind is at its maximum, it is at rest. Nothing is done consciously or unconsciously. It was a shock to the writer to discover with the aid of the retinoscope that the greatest strain of the body occurred during sleep. Strain is always accompanied by a loss of mental control when things go wrong. Accidents, fatal accidents, always mean a loss of mental control. The fact should be demonstrated. It should also be demonstrated that it is more difficult to fail than to succeed.

the day there should be a strong desire on the patient's part to put on glasses again, all he has to do is to close his eyes for part of a minute and remember that sign. Instantaneous relief sometimes follows and this encourages the patient to practice. These small test cards are always available at the Central Fixation offices for a very small sum and there is always someone there to explain how the card can be used successfully.

Children like the small test card with numerals. The numbers are distributed so that wherever the eye glances there is always some number which can be seen perfectly within a normal distance from the eyes. Children, as a rule, are not satisfied until the card can be read normally with each eye separately. Over each line of numerals there is a small number indicating at which distance the normal eye should read it. School children who have never been to the office or seen Dr. Bates or myself have been able to improve their imperfect sight to normal by the daily use of this small card.

Sometimes children do need encouragement from their parents or from their school teachers, because they forget just as grown folks do when a thing should be done for their benefit. I have been asked this question many times: "How about younger children who cannot read or write?" For them we have a card called the "pothook" card which contains inverted "E's." It does not take long for a two-year-old to be taught how to say which way the "E's" are pointing. Children soon learn how to say whether the "E's" are pointing up, down, left or right. By shifting from one "E" to the other, they notice the white spaces between the lines of "E's." Unconsciously they notice that the black letter "E's" become blacker or appear to, which is a good thing for the sight.

The "pot hook" test card is also used for sailors who have difficulty in reading flag signals at sea. Many mid-shipmen from Annapolis are at the present time using this card for the benefit of their sight.

There is a small black card with white letters for those who are partially blind, which is of great benefit to them. Such a patient is placed with his back to the sunlight and while the sun is shining on the black card, the white letters appear more clear and white and by closing the eyes often, avoiding the stare, the vision is not only improved, but if there is any pain or discomfort it soon disappears. The patient is advised to hold the card up close to the eyes and while the card is moved slightly from side to side about an inch or two, relief soon comes. The patient is then advised to hold the card a little further away day by day.

Patients to whom the large test card beginning with the letter "C" is given at the first visit find the pocket size test card, which is a duplicate of the large one, a great help. They shift from the small card, which is held in the hand, to the large card which is placed ten, fifteen, or twenty feet away. **The patient looks at a letter of the small card, closes the eyes to rest them for part of a minute and then looks at the card in the distance and sees the same letter on the same line,** (Switching close and far on identical familiar objects) which in most cases becomes clear and easy to see without strain.

For those who do close work, more than one small test card is used. During work hours two cards can be placed on the desk, for instance, or near to their work. One is placed to the left and the other to the right at an even distance of about two or three feet, or a little closer. The shifting, which is done rapidly and only takes a second to do, is done by first shifting from the work to the card at the left, back to the work, over to the card on the right and back to the work.

The patient soon notices that the small letters which were not seen clearly appear distinct. There are times when patients become discouraged because the sight does not appear to improve as rapidly as they expect. Sometimes the vision even becomes lower, which is discouraging. If those patients who have been to Doctor Bates can get in touch with him and explain just where the difficulty lies, the advice that will be given is sometimes all that is necessary.

I hesitate to mention my book to the subscribers of our magazine, but I always mention it to my patients. In it I have described as carefully as I could how important it is for patients to continue practicing after they have seen the Doctor. It is written so that everyone with eye trouble will find an article which will apply to his case. Those who have Dr. Bates' book find my book of additional help, and it is because of this that I mention it at this time. At the time the articles for my book were written, I had some blind and partially blind patients, an account of whose cases can be found in my book. Since the book has been written I have had further experience in treating difficult cases, which I try to explain in each number of the magazine.

I have found that **practice with microscopic type is most helpful in near-sightedness.** The patient holds the fine print as close as he can, looking at the white spaces between the black lines of type while blinking and then looking out of a window, for example, or at a distant corner of the room. Then looking at, shifting on the black fine print, remembering, imagining and seeing the fine print dark black and clear, then looking to the distant object and remembering, imagining, seeing it clear. Practice shifting on, remembering, imagining the fine print, then distant object, then fine print again, then distant object again... clear with the eyes: open, closed, open. Practice with both eyes together, then one eye at a time, then both together again. If vision is less clear in one eye, practice extra time with that eye to bring the vision equal, perfect in both eyes. Patch the eye not in use.

As I have said in this magazine before, all cases cannot be treated alike. There may be in one room at the same time ten or more cases of myopia, cataract, glaucoma or any other disease of the eye, and yet perhaps only one of the group would respond to one kind of treatment. For that reason, all cases have to be studied by the doctor or teacher and if one method of treatment does not help, another method must be applied immediately, so that the patient does not become discouraged. It takes just as much time in a great many cases to cure a simple case of imperfect sight as it does a more serious eye trouble, and yet it does not require a college education to be able to be cured of imperfect sight by the Bates Method.

Switching, shifting on letters on two - three identical eyecharts (or 2-3 identical fine print cards) at two-three different close distances improves close vision and reading distance.

Shift on letters on two identical eye charts placed at close and far distances. Use the memory, imagination; Shift on and remember, imagine the letters clear with the eyes open, closed, open.

Shift on letters on two identical eye charts placed at two different close distances to improve: accommodation, unaccommodation, convergence, divergence and clarity of vision at all close distances.

## Questions And Answers

Q - (1) How long should one palm and how often?

(2) How young a patient can you treat by this method, and up to what age can you expect results?

(3) Is astigmatism curable by this method?

A - (1) As often and as long as long as possible.

(2) Age is not a factor in the cure of imperfect sight without glasses. Patients as old as eighty-two have been relieved. Children can be treated as soon as they are able to talk. Babies, children can be rocked, swung in their mothers arms, cradle..., different objects moved in front of the eyes to prevent staring, to get the eyes shifting, activate relaxation.

(3) Yes.

Q - How long has the method been known?

A - Its evolution began thirty-five years ago. It has improved as experience has been gained and is still improving.

The Modern Bates Method consists of many new, improved versions of the original treatments and new methods; Left and right Brain Hemisphere activation, integration, color treatment, Infinity swing, posture, movement, positive thoughts/emotions are a few examples.

Q - Why is it a rest to read fine print? I should think it would be more of a strain.

A - Fine print is a relaxation, large print a menace. The December, 1919, issue of this magazine explains this in detail.

Fine print activates perfect central fixation, tiny shifting eye movements, short swing, fine tuned detailed vision. The mind, eyes become perfectly relaxed when reading fine print because that is the only way it can be read.

Q - Must the body be at rest before the eyes can be cured?

A - When the eyes are relaxed, the whole body is relaxed.

Q - Which is more beneficial, the short or the long swing?

A - The short swing, if you can maintain it.

Short Swing Example: Shift on a small fine print letter or period and see it show oppositional movement.

Q - Trying to make things move (oppositional movement) gives me a headache. Palming gives me more relief. Why?

A - Making an effort to do a thing will not help you. When you are walking on the street, the street should go in the opposite direction without effort on your part. Some people get more relief from palming, while swinging helps others more.

Q - Are the "movies" harmful?

A - No. Quite the contrary. Send for the magazine on this subject.

Q - Why do "movies" hurt my eyes when they should benefit them?

A - Unconscious strain. Do not stare at the pictures, but allow the eyes to roam over the whole picture, seeing one part best. Also keep things swinging.

Q - Is a hemorrhage on the outside of the eyeball fatal?

A - Rarely.

Q - Is central choroiditis curable and does it require much treatment?

A - Yes, choroiditis is curable. It requires a great deal of treatment in some cases.

Q - Should one imagine a thin white line along the top of a word or sentence or just at the bottom?

A - If you can imagine it at the top as easily as you can at the bottom, do so, otherwise imagine it only at the bottom.

Q - If the lens is not a factor in accommodation, what is its purpose?

A - The lens is for protective purposes, just as fat is a protection to the bones of the body.

The lens also bends/refracts light rays, focuses the rays onto the retina. The cornea also refracts/focuses light rays. The cornea and lens also control the amount of light that enters the eye. Most eye professionals state the lens also changes shape to produce accommodation, adjust light rays from close objects to focus on the retina.

Light rays from close objects diverge; this is why the lens/eye must change shape to bring the rays onto the retina for clear close vision.

Light rays from distant objects are basically parallel, focus perfectly on the retina so the lens/eye do not need to change shape to focus light rays from distant objects onto the retina. The round eye shape is set perfect for focus of parallel light rays.

Dr. Bates stated that the lens does not produce accommodation. He states that the outer eye muscles (oblique) slightly lengthen the eye (as a camera works) to focus on close objects.

Q - If strain is the cause of imperfect sight, why are not all affected in the same way? Why is it that some have myopia, others astigmatism, etc.?

A - Different people react in different ways to strain. Some have mind strain, some nerve strain, some physical strain, etc. All these tend to cause various ailments. One's temperament also has a great deal to do with it.

One strain can lead to secondary, and third...strain, all which increase each other. Example: A persons uses incorrect posture and experiences neck tension which results in some eye muscle tension and slight blur. This is the first type of strain. Then the person squints, stares, uses effort to see. This causes a new secondary type of strain and increased blur. The person begins to worry about the blur, eyestrain and a new third strain (worry) occurs, and more blur. The person starts wearing eyeglasses which is a forth strain and greatly increases all four strains. Four different types of strain are now in the visual system, mind.

The Natural Eyesight Improvement teacher shows the student how to identify and remove all types of strain.

Left and right brain hemisphere imbalance, dominance, suppression, negative thoughts, emotions, using effort to see at close and far distances, squinting, staring can cause different types of strain, unclear vision at certain distances, other abnormal eye conditions.

Q – When doing the swing, what does one move, the head or eyes?

A – The eyes are moved in the same direction as the head is moved.

Q – Does massaging benefit the eyes?

A – No, because it does not relieve the mental strain which caused the eye trouble.

Modern teachers know that; Body, shoulder, neck, face acupressure point activation and muscle massage does improve the sight, health of the eyes by relaxing the eye muscles, improving eye movement, blood, oxygen, lymph, nerve flow/circulation to the brain, eyes. Joint, vertebrae alignment, muscle massage, relaxation in many different areas of the body has a direct affect on the eyes and improves the clarity of vision.

Improving the state of the body, its relaxation helps remove mental, visual strain.

Applying Bates method also removes strain in the mind, eyes, body, muscles, nerves.

Q – Is practicing under a strong electric light as beneficial as practicing in the sun?

A – If the sun is not shining, the strong electric light can be used with benefit, although more benefit is derived from direct sun treatment.

Q – Can one remember perfectly and see imperfectly?

A – It is impossible to remember perfectly and see imperfectly at the same time. Perfect sight can only be obtained with the aid of a perfect memory. When the memory is perfect, the mind is relaxed and the vision is normal. Imperfect memory requires a strain of the eye which produces imperfect vision.

Q – Can one blink too quickly and too often?

A – The normal eye blinks quickly, easily and frequently. Blinking can be done correctly or incorrectly. Some people, when they are told to blink, squeeze their eyes shut, or close them too slowly and then open them spasmodically, which is wrong. When the normal eye blinks, things are seen continuously.

## Announcement

Dr. Bates wishes to announce to his patients that he is moving his offices from 383 Madison Avenue, New York City, to 18 East 48th Street and will be treating patients at the new offices after October 1<sup>st</sup>.

The Central Fixation Publishing Company will also be located in the same building, 18 East 48 Street, New York City.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

OCTOBER, 1928

### No Glasses For Quick Results

The first and best thing that all patients should do after their first treatment, or before, is to discard their glasses. It is not always an easy thing to do but it is best for the patient and for the teacher. It is true that at one time I did not encourage patients to learn the treatment unless they discarded their glasses permanently. But since I have studied more about my method and have encouraged some of my clinic patients to wear their glasses at times while under treatment, I find that **some of them obtained a cure but it required double the amount of time that was required to cure those who discarded their glasses permanently.** During the treatment when the glasses are worn temporarily, even for a short time, the vision sometimes becomes worse and in most cases a relapse is produced. It is much more difficult to regain the lost ground than ever before, and sometimes causes much discomfort.

Glasses for the correction of myopia do not fit the eyes all the time. To obtain good vision with glasses an effort is required to make the eyes change their focus to have the same error of refraction as the glasses correct. When the vision is benefited most perfectly by glasses it is necessary for the eyes to change frequently. To learn the amount of myopia in the eyes by trying different glasses to find the glass which continuously improves the vision best is usually difficult because the amount of the myopia changes so frequently. To change the amount of myopia requires an effort. Some people complain that no glasses fit their eyes permanently. These cases are benefited by discarding their glasses for a longer or a shorter period while being treated. Patients who require good sight to earn a living and find it difficult to discard their glasses while under treatment, have been able to make slow or rapid progress in the cure of their imperfect sight by wearing their glasses only when it was absolutely necessary.

Modern teachers allow the use of reduced, weaker, 20/40 eyeglass lenses if necessary for driving, safety until the Bates Method brings the vision to a level of clarity where eyeglasses are not needed. The strength of the lenses are repeatedly reduced as the vision passes through clearer and clearer levels of clarity. Reduced lenses do block natural eye function, produce strain, eye muscle tension, slow vision improvement but not as much as 20/20 and stronger eyeglass lenses. Reduced lenses allow the eyes, vision to improve, reverse back to a normal state. The lenses are worn as little as possible and a further reduced pair is kept ready since the Bates Method can bring a sudden, sometimes unexpected increase in vision improvement. As vision improves, stronger lenses will not provide adequate clarity.

## Nystagmus

By W. H. Bates, M.D.

When the eyes move conspicuously from side to side, regularly or continuously, the condition is called nystagmus. These movements occur so frequently in connection with serious diseases of the eyes that the presence of this symptom is an indication that the cure of the eye disease will usually require much time and attention. So seldom are eye diseases with nystagmus cured that many physicians believe that most cases with nystagmus are incurable. I have found that many of these so-called incurable cases

will recover by treatment.

We have observed that many eyes with imperfect sight do not have nystagmus but acquire it at almost any age. It has been produced repeatedly by a conscious stare or effort to see. **It has been relieved by conscious relaxation with the aid of palming.** When the patient is reminded that the stare or an effort to see is injurious, he becomes better able to lessen or relieve the eyestrain which is usually very harmful. Patients with nystagmus have less control of the movements of their eyes and for this reason require more supervision and help before they become able to use their eyes properly without strain.

All patients with nystagmus cannot be treated in the same way because I have not found two alike. The treatment which is helpful in one case may not be of any benefit to any other.

One patient, a woman aged twenty-five, who was born with a very bad case of **nystagmus** and who also had **mixed astigmatism**, with **retinitis pigmentosa**, was under my observation at different times for a number of years. In the beginning her vision without glasses was 10/200 in each eye. She obtained a vision of 10/70 in each eye with the aid of the glasses which corrected her mixed astigmatism. Without glasses her vision improved to the normal temporarily with the aid of **palming, shifting, and swinging.** She also became able to read without glasses. The nystagmus was also benefited at the same time. The patient was encouraged and practiced the relaxation exercises more continuously.

In her case, palming was the most beneficial treatment of her eyes, both for the nystagmus and vision. This may have been due to the fact that when she palmed with both eyes closed, she was able to remember black letters on a white card more perfectly with her eyes closed than with her eyes open. She was also able to remember or imagine white letters on a black card better with her eyes closed than with her eyes open. **When she remembered letters perfectly, her eyes became relaxed and her vision for trees, flowers, the colors of the spectrum, red, green and blue as well as other objects and other colors was perfect** without any effort or strain whatever. Her memory seemed perfect to her because she could remember letters and other objects as well at twenty feet or farther as she could at two feet or nearer. **Palming helped her to remember things better. The longer she palmed the better became her memory. With an improved memory her sight became much improved and the nystagmus became less.** The palming improved her memory of the notes of her music. Many of the black notes had a white center which she remembered better by the aid of palming.

It is important to mention that the **sun treatment** also lessened the nystagmus and improved the sight because the eyes became relaxed. This improved her sight and lessened the nystagmus. In the beginning the sun treatment was not so beneficial as it became later, after palming. **The sun treatment was employed with the aid of a strong magnifying glass which focused the light of the sun on the outside of the upper lids, the glass being moved rapidly from side to side for short periods of time.** For several weeks this treatment was given daily whenever there was sun, and the nystagmus and vision decidedly improved.

(There have been cases of nystagmus treated which failed to improve by the sun treatment. Other methods were then employed.)

With the improvement of the nystagmus, this patient's vision for distant objects and her ability to read also improved. The inflammation of the retina at the same time improved remarkably. In the beginning of her treatment a large part of the retina of both eyes was covered with black pigment spots. The ophthalmoscope was used each time she came. **It was noted that these black specks became less numerous and finally disappeared. The fields of each eye were improved and the night blindness from which she suffered became less.**

Her visits to the office were very irregular and uncertain, with the result that the improvement which she obtained during this time was not continuous. She earned her living as a music teacher. When she neglected to practice the treatment which I recommended to correct the tension, stare, and strain, her vision became worse and she lost her occupation. Having to depend upon her family for support was embarrassing to her. She came again for treatment after an absence of over a year. She told me that she was ready to come at regular intervals whenever I advised her to come.

While she was away she had a relapse but did not lose all the improvement that she had gained; there was an improvement in the nystagmus, but it was not rapid or conspicuous. This patient was examined with the aid of a moving picture camera. She was able to lessen the movement of her eyes and was able to show on the screen how it was done. When these pictures were taken by an expert, the doctors who were invited to be present testified that when the nystagmus became less or disappeared and the vision improved it was because the stare, strain, or effort to see was corrected. What I have been unable to prove in my publications, the moving picture (movie) screen proves.

My patient gradually and steadily improved until she became able to see well enough to resume her work. Her vision for distant and near objects improved so that she could see better without glasses than she had formerly seen with them.

While the moving picture work was in progress, this patient offered her services to show how the nystagmus could be produced by an effort. The condition of her eyes was so much improved that I doubted that she had the ability or the courage to strain or produce the amount of tension necessary to show her nystagmus condition on the screen. While the camera was running I was amazed to see the nystagmus return. I thought that I had met my Waterloo. Now that I had improved a case that I had at one time deemed impossible to help, I feared that in order for her to strain sufficiently to cause the nystagmus to return would be a calamity. My fears were relieved when the camera again registered a picture of her while she remembered perfect sight by reciting for me all the letters of the Snellen test card which she had committed to memory.

This picture showed plainly no evidence of effort or strain and the nystagmus had stopped. Later the patient told me about the pain and discomfort she suffered in order to produce the nystagmus for the picture. Her sacrifice was worthwhile because others since then have been benefited.

Some patients with nystagmus do not know that they have it. **The first step in their cure is to teach them to feel the eyes move when the closed upper lids are lightly touched with the finger tips.**

### Boy creates and cures nystagmus

One day some years ago a boy about twelve years of age came to my office. He was ushered in by his mother, a middle aged woman who just pointed to his eyes, and then sat down and waited. The patient had nystagmus. His vision was about one-half of the normal. With the ophthalmoscope no disease of the retina, optic nerve or any other part of the eyes could be found. The nystagmus was variable. He was able to lessen it until his vision improved very much and even became normal, 20/20 for short periods of time. By straining to see, the nystagmus became worse and his vision less. His mother became more interested. Her eyes were full of questions but she remained silent.

I asked the boy; "Can you move your eyes more rapidly?" "Yes," he answered. Then he was asked: "How is your sight?" "Very poor," he replied, "and growing worse." "Can you stop the movement of your eyes?" He answered: "Yes." "How do you do it?" "I

do not know," was the reply.

He was told to palm or to cover his closed eyes with the palms of his hands. He said this felt restful and when he opened his eyes his vision was improved and the nystagmus had stopped. For some minutes he was able to demonstrate that he could stop the nystagmus and that his sight for a short time was better. He was also able to produce or increase the nystagmus by making an effort to try to see. All this time his mother watched the proceedings. By the way she acted one could read her mind. The nodding of her head, the frequent moistening of her lips, the satisfied look in her face showed that she believed that the boy produced the nystagmus consciously for his own amusement, which was the truth. It was not necessary for me to explain. She now understood what was the matter with him and she also knew what to do. After thanking me she grabbed the boy's arm none too gently and disappeared from my office quicker than she came in.

There is another story of a child that created crossed, wandering eyes as a joke. The child's eyes normally did not cross, wander. Dr. Bates cured many cases of crossed, wandering eyes by teaching the person how to create it. Once the person knows how it is produced (using strain, tension, incorrect eye function), the person can prevent, cure it by avoiding the strain... and by applying relaxation, shifting, central fixation... Nystagmus can also be caused by a medical condition in the body, brain. Check with a medical doctor for more treatments.

## Case Reports

By Emily A. Bates

Emily C. Lierman married Dr. William H. Bates. Her name is now written as: Emily A. Bates

It is encouraging to meet people who have become able to discard their glasses by the benefit they obtained just from reading Dr. Bates' book. There are those also who write to us and complain that they have not received any benefit whatever after reading it. But the latter are in the minority.

Sometimes I feel that I would have been one of the complaining kind if I had not been fortunate enough to meet Dr. Bates before his book was written. I agree with some people that parts of his book are too technical for the layman to understand. But the principal part of his book is not technical and is so carefully written that even school children have been benefited and cured by practicing the methods recommended. While I was in California I met a number of children who came to see me for one visit only and brought Dr. Bates' book with them. Dr. Bates' himself would have felt honored if he could have seen so many of his books so worn out that the pages had to be pasted together again, while others were very much soiled from handling.

These children wanted to be sure that their relief from eyestrain was complete. I appointed the oldest one to test the sight of each eye of all the pupils. According to the tests made, the vision of all the pupils was normal with the Snellen test card and other objects. They all read correctly the captions on the moving picture screen, thirty feet away. A question was asked as to whether the moving pictures (movies) caused more or less eyestrain and I replied that the facts were quite the contrary, but that one must become accustomed to the strong light of the sun. Most children out West are accustomed to the sun and for that reason there are fewer children wearing glasses than the children of city schools here in the East. Doctors and instructors from various schools came to learn the Bates Method so that they could teach others how to use their eyes correctly.

A young woman came to me for the relief of her eyestrain. While visiting in New York, one of the professors of the University of Southern California had been treated and cured of presbyopia by Dr. Bates. This woman was one of the professor's students at the University and he recommended her to come to me for treatment. She had myopia, or shortsight, (nearsighted) and at times suffered a great deal of pain, especially at night after her studies were over. It was impossible for her to read at night no matter how strong an electric light was used. The stronger the light was, the more discomfort she had in her eyes. This made her unhappy because she was a lover of books. The temptation was very strong to obtain suitable glasses so that she could enjoy reading her books at night, when the instructor advised her to try the Bates Method for the relief of her eyestrain.

I began treating her by placing her fifteen feet from the test card which was fastened to a stand. With much straining on her part she read the seventy line with her right eye and only saw the largest letter on the card, which is called the two hundred line letter, with her left eye. I immediately decided to draw the test card up to ten feet, where she would not strain so hard to see. Again she read the letters, reading with the right eye and then with the left. Her facial expression became more natural, less strained, and without her telling me so, I knew that she felt more like going on with the treatment.

Her disposition was directly opposite to that of her friend and classmate who came with her. Her friend was so determined not to wear glasses that there was no doubt at all in her mind about receiving some benefit from me. But not so with my patient. She was willing enough to have me try to help her but she did not have much faith in me. I was not Dr. Bates and that made a difference with her. She felt that I could not possibly understand her case. She told me later that I had read her mind correctly but was glad that she tried and won out.

At ten feet she read the forty line with her right eye with the evidence of strain decidedly less. With her left eye she read one letter correctly of the one hundred line, or the second line from the top of the card, which is an "R." The other letter on that line is a "B" which she thought was an "R" also. I did not correct her but told her to close her eyes and forget about the test. I asked her about the subject she was most interested in at college and she seemed eager to tell me about it. She was studying art and the correct combination of colors for interior decorating. Some patients, when asked to close their eyes and remember something perfectly cannot do so without help from the doctor or instructor. This patient did so immediately. She did not have her eyes closed for more than ten minutes when she became able to read the whole test card as well with the right eye as with the left, at ten feet.

**The memory of colors**, describing them to me while her eyes were closed, was all she needed to give her relaxation of mind and body, and temporarily improve her sight to normal. I told her to close her eyes again and describe her ideas of colors for different rooms of a home she had in mind. While she was doing this I

Shift on letters on the eyechart with both eyes together, one eye at a time, then both together again. Practice a little more with the eye that needs vision improvement.

Palming and remembering, imagining a favorite subject, (Art), the colors, pictures she draws relaxes the girls mind, body, eyes and the eye chart is then seen clear.

Sunning - face the sun, eyes closed, move the head side to side.

Read fine print a few times each day in the sunlight after practicing sunning.

again placed the test card fifteen feet away and with both eyes she read 15/20. She complained of a sharp pain over both eyes, the pain being more over the left eye.

I placed her chair in the sun and while her eyes were closed I used the sun glass very rapidly for five minutes on her closed eyelids. This not only relieved her pain but it improved her sight to 15/10. She read microscopic type just as well in an ordinary light as she did in the sunlight. Because she had been nearsighted it was not difficult for her to read it. She was told to read the fine type several times every day after sitting in the sun with her eyes closed.

Having worn a green shield over her eyes while in her classroom every day for two years, it was not easy for her to take the sun treatment. However, the results she obtained during her first treatment encouraged her to continue the practice. She purchased a sun glass and I taught her friend how to use it on her eyes. My patient in turn also learned how to give the sun treatment which not only benefited her friend but also others at the University. My patient returned for two more treatments a month apart and after that she reported over the telephone to me that she had had no relapse to imperfect sight.

## Questions And Answers

Q - Will it still be necessary to continue practicing the methods of swinging and shifting after my eyes are cured?

A - No, when you are cured of eyestrain you will not be conscious of your eyes. However, if you strain them you will know what to do to relieve the strain.

Q - If one's arms become tired while palming, will a black silk handkerchief covering the eyes produce the same amount of relaxation one gets from palming?

A - No. Palming is the best method for relaxation and improvement in vision. When tired of palming, the hands can be removed and the eyes kept closed until one feels relaxed.

Q - How can one look at the sun without injury?

A - While looking toward the sun it is best to **blink the eyes and to look to the right and to the left of the sun.** (shift) This will help you to look directly at the sun without discomfort or pain. One cannot look directly at the sun without normal vision.

Q - If I improve the vision of the poor eye will there not be a confusion of images?

A - Not necessarily.

Q - Is it possible to cure a three-year old child of squint without an operation?

A - Yes. I have had many such cases that were cured by my method of treatment.

Q - When the pupils become dilated, is that an indication of eyestrain?

A - No. A great many people who have dilated pupils have no trouble at all with their eyes.

Q - I am practicing the methods in your book to cure myopia and astigmatism. Sometimes for short periods, I see perfectly, then things fade away. Can you explain this?

A - This is what we call getting flashes of perfect sight. With continued practice these flashes will come more frequently and eventually will become permanent. Then you are cured.

Q - Can the vision be improved without glasses after the lens has been removed for cataract?

A - Yes.

Q - Does Dr. Bates approve of dark glasses to protect the eyes from the glare of the sun at the seashore?

A - No. Dark glasses are injurious to the eyes. The strong light of the sun is beneficial to the eyes, although it may be temporarily painful and blinding.

Q - By following instructions in the book, can cataract be benefited without consulting a physician?

A - Yes.

Q - Are memory and imagination the same? When we remember an object do we have to visualize it?

A - A perfect memory cannot be obtained unless you are able to imagine that you see or visualize what you remember.

Q - When I try to imagine a black period, it blurs and I get all colors but black.

A - When you fail to remember a period with your eyes closed, open your eyes and see it, then close your eyes and remember it as well as you can for a moment. Alternate.

Shift on the period with eyes and mind and a clear mental, visual image will be seen and imagined.

Q - I enjoy palming, but it makes me drowsy after ten or fifteen minutes. Is this helpful?

A - When palming is done properly it does not make you drowsy.

Q - I find conscious blinking a strain because I close my eyes temporarily and seem to hold the eyeball stationary. If I shut my eyes for a longer period would that be blinking? Stationary eyes=muscle tension, strain, blur.

A - No. The normal eye blinks consciously or unconsciously without effort, without strain, and quickly.

Q - My little daughter has temporary perfect sight while palming, but her eyes turn in when she plays excitedly or strenuously. I thought play was relaxing.

A - Play may be relaxing and should be beneficial but like other things, it can be done wrong with a great effort without benefit.

Q - While palming, is it necessary to close the eyes?

A - Yes.

Q - How long is it necessary to read the test card before obtaining benefit?

A - Some patients, by palming and resting their eyes, have obtained benefit in a few minutes.

Q - What is most helpful when one is dreadfully nearsighted and finds it almost impossible to see without glasses?

A - Practice palming as frequently as possible every day. Keeping the eyes closed whenever convenient for five minutes, ten times a day, is also helpful.

Q - Why is fine print beneficial?

A - Fine print is beneficial because it cannot be read by a strain or effort. The eyes must be relaxed.

Fine print also activates perfect central fixation, with eye movement/shifting, including tiny shifts.

When the mind, eyes are relaxed, vision is clear.

Perfect relaxation must occur for fine print to be seen. Reading fine print brings the mind, body, eyes to perfect relaxation.

Q - I have noticed when I palm that my eyeballs hurt from the pressure. When I loosen this tension the light filters in.

A - Palming is done correctly with the fingers closed and laid gently over each eye, using the palms like a cup. If this is done properly there is no pressure and the light is shut out.

It is ok if a little light shines thorough.

The hands must stay relaxed. No pressure on the eyeballs, eyes.

Q - Are floating specks serious? Sometimes they just flood my eyes like clouds of dust and greatly frighten me.

A - Floating specks are not serious. They are always imagined and never seen.

Q - I have improved my sight by palming, but when I read for any length of time the pain returns.

A - No, it is not advisable to read that way because it is a strain, causes eye muscle tension and alters the shape of the eyeball and more continuously.

Q - If type can be seen more distinctly with the eyes partly closed, (squinting) is it advisable to read that way?

A - No, it is not advisable to read that way because it is a strain, causes eye muscle tension and alters the shape of the eyeball and leads to increased blur.

Q - I have attained normal vision, but after reading for a while, my eyes feel strained. Would you still consider I had normal sight?

A - If your eyes feel strained you are not reading with normal vision.

Q - When I look at an object and blink, it appears to jump with each blink. Would this be considered the short swing?

A - Yes. You unconsciously look from one side to the other of the object when blinking. (Oppositional Movement)

Q - Some days, I can read the Snellen card to the 15 line, others only to the 30 or 20.

A - When the eyestrain is less the vision is always better.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

NOVEMBER, 1928

Practice Time

A large number of people have bought the book "Perfect Sight Without Glasses" but do not derive as much benefit from it as they should because they do not know how long they should practice.

**Rest:** The eyes are rested in various ways. One of the best methods is to close the eyes for half an hour after testing the sight. This usually improves the vision.

**Palming:** With the eyes closed and covered with the palms of both hands the vision is usually benefited. The patient should do this five minutes hourly.

**Shifting:** The patient looks from one side of the room to the other, alternately resting the eyes. This may be done three times daily for half an hour at a time. The head should move with the eyes and the patient should blink. Shift relaxed, easy, continually from object to object and part to part on objects.

**Swinging:** When the shifting is slow, stationary objects appear to move from side to side. This should be observed whenever the head and eyes move. A faster shift produces faster oppositional movement.

**Long Swing:** Nearly all persons should practice the long swing one hundred times daily.

**Memory:** When the vision is perfect, it is impossible for the memory to be imperfect. One can improve the memory by alternately remembering a letter with the eyes open and closed. This should be practiced for half an hour twice daily.

**Imagination:** It has been frequently demonstrated and published in this magazine that the vision is only what we imagine it to be. Imagination should be practiced whenever the vision is tested. Imagine a known letter with the eyes open and with the eyes closed. This should be practiced for ten minutes twice daily.

**Repetition:** When one method is found which improves the vision more than any other method, it should be practiced until the vision is continuously improved.

## Hypermetropia

By W. H. Bates, M.D.

**NEAR-SIGHT** or myopia (unclear distant vision) is acquired in schools. The statistics of many observers show that myopia may increase in frequency. This increase may be slight or it may be considerable.

**HYPERMETROPIA** (farsight, unclear close vision) is the opposite of myopia. The optic axis is shortened instead of being elongated as in myopia.

Most writers attach very little importance to hypermetropia. They publish that the hypermetropia eye is usually congenital and not acquired. Risley examined many eyes with hypermetropia. He believed that hypermetropia caused headache, pain, fatigue, dizziness and other symptoms to a greater degree than did myopia. Many statistics showed that in the eyes of school children about 80 percent had hypermetropia, about 10 percent had myopia, and about 10 percent had good eyes. It is well that the objections to hypermetropia should be studied and published. It is more necessary to relieve the symptoms of hypermetropia than those of myopia if for no other reason than the fact that hypermetropia is more injurious to the eyes.

The old methods recommended for hypermetropic eyes are insufficient to obtain the best vision, and to relieve or cure pain, fatigue, dizziness, double vision or other nervous troubles. Hypermetropia of low degree is quite often as difficult to improve without glasses as many cases of hypermetropia of a high degree.

What are the limits of improved or cured vision in most cases of hypermetropia? There is no limit. A hypermetropia of 15 D.00 or 30 D.00 can obtain as good sight by relaxation treatment as a hypermetropia of 1 D.00 or less. Such claims are open to criticism. They can all be demonstrated by different operations on different cases.

What is the percentage of cured cases or what is the percentage of failures? A physician in charge of a physiological laboratory many years ago requested a report on the production or cure of hypermetropia in animals or in human beings. The report submitted to him stated that 100 percent of all rabbits, dogs, turtles, cats, fish, and other animals acquired hypermetropia after the recti were advanced or strengthened, while the obliques were divided or weakened.

The director of the laboratory asked: "Why do you not publish the facts?" The answer was: "Because no failures have been observed." He then added that he felt that when successful results occurred in 60 percent of his cases he should publish the results because they were of scientific value.

A failure was desired before a correct conclusion could be stated, that is, a case in which hypermetropia was not produced by some form of operation but could be obtained by another operation. In order to produce nearsightedness in a cat it is necessary to strengthen the oblique muscles with the aid of sutures or silk thread. Now when the recti muscles on the outside of the eyeball are strengthened by the advancement of these muscles, hypermetropia is produced.

In the early days of scientific medicine the facts connected with the changes that might take place in the hypermetropic eye were studied and they might have been a benefit if the facts were understood, but these men did not realize the importance of many truths which they demonstrated. In those days, as in our own, science was not governed by ordinary rules. For example, Donders published in his book the claims of some ophthalmologists that hypermetropia was not curable because they had never seen any such cases cured. Yet most eye doctors in the early days reported the truth correctly.

After extraction of cataract, the amount of hypermetropia is about 10 D.00. In most cases they admitted that the hypermetropia became less without any treatment, and that the eye, after extraction of cataract, had been observed to become normal without any hypermetropia, when the patients were able to not only obtain perfect sight for the distance but also were able to read fine print or diamond type at six inches from their eyes without any difficulty.

One doctor stated the changes which took place in eyes which had considerable hypermetropia. It is difficult to understand why it is that this doctor published that an effort to see always increased the amount of hypermetropia and for that reason no treatment could be expected to help these cases. One physician, whose scientific attainments were unusual, published statements like this: "I have never cured hypermetropia and because I have never cured hypermetropia nobody else can." Another so-called authority, after testing results obtained from massage of the muscles of the eyelids, could see no benefit from this treatment. He was asked by a friend: "Are you still using massage?" He answered: "Yes." Then his friend said: "Does it do any good?" The doctor answered "No." "Why do you do it then?" "Because there is nothing else to do."

**An effort always increased the hypermetropia and makes the sight worse.** This is a fact so universally true that it is unfortunate that the physicians who found that a strain was bad did not try the opposite of strain - relaxation. Those people who become able to read at a distance of less than twelve inches are unable to read by an effort. With a vision lowered by hypermetropia at twenty feet or farther it is very easy to demonstrate that a strain to see by concentration or some other effort always increases the hypermetropia. A strain to see at the near point produces hypermetropia, while a strain to see at the distance produces myopia.

Rest when properly employed cures all forms of imperfect sight. The great difficulty is that all people are not able to rest their eyes properly.

It has been found that the tendency of most people is to concentrate or stare. Concentration or an effort to concentrate is a strain which produces almost all cases of imperfect sight. When one letter of the Snellen test card is regarded continuously, without blinking, shifting, or a part of one letter of the Snellen test card is regarded continuously, without blinking, shifting, imperfect sight is produced. Trying to keep the eye immovable causes imperfect sight. The normal eye when it is at rest is always moving and sight becomes imperfect when an effort is made to imagine the letters or other objects stationary. It is not possible to keep the eye stationary without an effort. It is impossible to move the eye and keep it under a strain at the same time. When the eye moves 'shifts' relaxation and clear vision result.

If the patient stands with his feet about one foot apart and sways the body, head, and eyes from side to side, it is possible to obtain a movement of the eyes which is a rest to the eyes and a benefit to the vision. **When the sight is good continuously, the movement of the eyes is slow, short, easy, and continuous.** (Saccadic - very fast, high frequency shifting also occurs automatically.) When things are seen wrong or when the vision does not immediately improve, one can by touching the upper lid with the forefinger lightly, feel all kinds of movements of the lid muscles and this movement effects the eye itself. The proper movement which is beneficial can only be obtained when stationary objects are imagined to be moving.

Some patients obtain benefit from moving the eyes in a circular direction because when the eyes move continuously, there is no stoppage of the swing and no opportunity to stare. (Infinity Swing)

For years it has been observed that many cases of hypermetropia changed to myopia. The number of theories as to how this was brought about were numerous and not one of them would stand criticism for any length of time. One of the most important theories that was published was by Risley, who mentioned that a large number of cases of hypermetropia became changed to mixed astigmatism in which one meridian of the eyeball was more fixed than any of the others. This astigmatism was changed at first into mixed astigmatism. Later on it became a retraction of myopia. It was a very attractive theory which lost its value when it was found that no one case was observed continuously until the hypermetropia became changed to mixed astigmatism and finally myopia.

#### Experiments on Outer Eye Muscles and Clarity of Vision

One day the physician in charge of the physiological laboratory made a tour of inspection. He asked for information or for statistics of the experimental work that was performed on a rabbit to find the cause of accommodation. He desired to know why results of experimental work on the rabbits which were 100 percent successful were not offered for publication before. He was told that these had not been published because there had not been a failure. A few days later a failure came. Electrical stimulation did not produce myopia in the rabbit with hypermetropia. Here was the failure that we had been waiting for. There was much excitement when we failed to obtain myopic refraction. However, it was found that the rabbit was born without any inferior oblique. When the function of the inferior oblique was obtained with the use of sutures, with the aid of the retinoscope myopic refraction was obtained as readily as in eyes which had nothing wrong. The director told us that when his experiments were 60 percent of the truth that they could be considered a contribution to the science of medicine and should be consequently published. The director was told about the failure and he agreed with us that the publication of the failure was a very necessary thing to do. It might have ended here perhaps but it was believed that the 100 percent of successful operations were worthy of investigation, but so far as is known no one else has performed similar experiments to determine the truth of the results claimed.

There are some facts which ought to be emphasized. In the first place, hypermetropia is the most frequent cause of discomfort, pain, or imperfect sight. The medical men of the last century tried to prevent the harm done by hypermetropia just as they are still trying to prevent the harm that comes from near-sightedness or myopia. The younger men of today are not encouraged to work in this field, when some of the authorities can stand up and say: "If I fail no one else can succeed; I know all there is to know about the eye."

There are a number of people at the present time who are studying hypermetropia, but it is not being studied as much as it should be. I believe that every school, public and private, should devote a short time frequently to the prevention and cure of imperfect sight. I am very much opposed to the practice of most ophthalmologists who fit each patient with imperfect sight with glasses which are not indicated.

For some years I have found that a large number of cases of myopia were suffering from hypermetropia which produced disagreeable symptoms. It is really surprising that so many cases of hypermetropia have been neglected. They are more readily cured than the myopic cases, but when a man at the head of a medical department of the schools tells me that it is useless to treat hypermetropia because he failed, it means that he will do all that he possibly can to injure or to interfere with the methods practiced by other men.

When studying the works of Donders forty-five years ago I was very much impressed when he gave the histories of quite a number of patients who had been cured of hypermetropia and other errors of refraction by one or more operations and by other treatment. This was an encouragement to me to keep on studying the facts which occurred in hypermetropia. I wish to state here that I feel very grateful to Donders for the many things which he taught me. That which pleased me the most and benefited me more than anything else that I learned from other doctors was his claim that there were some cases of hypermetropia and other errors of refraction which could be cured by treatment. I am sure that he did not know how voluminous were the writings on the use of glasses or the importance of wearing glasses which were written under his name. It seemed as though there were many articles on the cure of hypermetropia which were not written by him.

Hypermetropia is curable. Being curable it can also be produced, increased, diminished, or modified. If it were not curable it would be difficult or impossible to do this.

The cure of hypermetropia is very simple. When one practices in the right way, a cure is always brought about. It takes no more time to practice in the right way than the wrong way. Hypermetropia is cured by rest, and cannot be benefited by an effort. When one regards near objects or parts of a letter at the near point, hypermetropia is always increased. (If diffusion, strain, effort, staring is applied.)

Practice with fine print is one of the best methods of relieving hypermetropia. The fine print is held first at the distance from the eyes at which the patient sees best and gradually brought closer until the patient can read it at six inches from his eyes. He should not look directly at the letters; he should look at the white spaces between the lines and imagine that there is a thin white line beneath each line of letters.

Look at the white spaces before reading the print. When the print appears clear; then look directly at the print and read it. If it blurs again, look back to the white spaces or at another object seen easily, clear, close or in the distance to relax the eyes. Then, when relaxed and close vision is clear again, return to the print. Reading fine print is one of the simplest, easiest cures for unclear close vision but opticians have been hiding this fact for years. It also improves clarity of distant vision.

Correct practice with fine print daily has cured hypermetropia.

## Hypermetropia

By Emily A. Bates

A woman, aged 63, who had been wearing glasses for twenty years decided to try the Bates Method and do without them. She called to see me for treatment while I was in the West and asked me when she first came if I would examine her eyes with the ophthalmoscope. As I was working by myself I was not permitted to use any instruments to examine the eyes so I did my work just the same and cured my patients without examining the eyes. Some patients were advised to see an eye specialist who took care of cases where examinations were needed. This patient had had eye tests made several times by eye specialists and opticians so I knew pretty well what her trouble was without the retinoscope or ophthalmoscope to help me.

Many cases like hers have come to me both in clinic and in private practice and with a few exceptions I am usually right after I have tested the patient with the Snellen test card. When this patient gave me a history of her case, she told me that in the

beginning when she first put on glasses her vision for the distance was not bad, but her sight for reading and sewing was poor and her glasses only helped her for a while. Eye drops and massage treatment were given her for the relief of eyestrain and headaches, but after a year of this treatment she had her glasses changed on the advice of her doctor. Her sight was tested again and she was told that her distance vision was impaired. Then she was advised to wear bi-focals or to have two pairs of glasses with her at all times. She tried bi-focals because she thought it would be much easier wearing only one pair of glasses, but she could not become accustomed to them so she tried two separate pairs of glasses.

As I listened to her explaining all this to me in her mild, soft way of talking, I could imagine how much discomfort she endured without saying very much about it and I could well imagine how anxious she was to get rid of her glasses altogether after having tried as faithfully as she had for more than twenty years. The last glasses which were given her for close work helped her to see better at the near point, but the strain and headaches came on periodically just the same. She tried massaging the eyes, thinking that this might help. She also went to Europe and tried different climates thinking that the change of air would be of benefit to her, but the pain in the back of her neck and in back of her eyes kept on just the same and at times became worse.

She obtained Dr. Bates' book and studied it according to the advice given for her particular case. She was able to do without her glasses for the near point but as her sight for the distance still troubled her a great deal she did not know how to go on by herself.

I began treating her by the palming method after I had tested her vision for the test card. Her vision in both eyes was the same, 10/30. When I placed the test card twenty feet away all the letters were blurred and she also had double vision when she tried to read the smaller letters.

She had traveled a great deal and liked to talk, so while she was palming, I encouraged her to tell me about a recent trip she had taken, and the memory of things which she had seen as she described them to me helped to improve her vision to 15/10 or better than normal with each eye separately. Before I tried another method I wanted to find out what caused her vision to be lowered at times and also what caused her pain and discomfort. During the course of a short conversation with her she told me of a very unpleasant experience she had had with someone whom she loved and who greatly disappointed her. I encouraged this conversation, not so much to get information from her but to have her talk about this unpleasant thing, which was interesting to her but not to me because I did not know the person under discussion. The patient palmed for ten minutes and I timed her especially to find out whether her vision would be the same for the test card after she had explained her unpleasant experience while her eyes were covered. I kept the test card at the same distance as I had before and when I told her to remove her hands from her eyes and to look at the test card and read it again, she said that with the exception of the three upper lines of letters all the rest of the card was blurred.

I knew immediately that speaking of or thinking about unpleasant things was the cause of a great deal of strain. I did not tell her so right away but she was eager to explain that this was the way her vision was a great deal of the time. It was lowered at times when she suffered discomfort and pain; then at other times her vision was good without any sign of strain. She did not realize that while she was palming and explaining about her unpleasant experiences that the thought of what she was telling me caused all her trouble or a great part of it. (negative, unhappy thoughts, emotions=mental strain, eye muscle tension, blur...) When I finally explained it to her, she believed that I was right. I did not have her close her eyes again during her first treatment, but I placed her by the window where the sun was shining and I gave her the sun treatment while her eyes were closed, using the sun glass on her upper eyelids. The sun was quite hot so I had to use the sun glass rapidly and for only a few seconds at a time.

After this treatment, I told her to sway her body slightly with a short sway from side to side, glancing at the test card in my room and then as she swayed toward the window to look at a distant sign about two city squares away. At this distance she read a sign which was painted on the side of a large building. She saw all the letters clearly and read them without any hesitation whatever. This seemed a revelation to her because it was something she could not do for many years without her glasses. She kept up the sway as I directed her, but at times I had to encourage her not to stare as she looked at the test card, while she swayed toward it.

She asked me to explain to her why the test card looked more clear to her at times only, so I told her to do the wrong thing, stare at the letters, for instance, as she looked at the card about ten feet away from her eyes. I also told her to look off at the distance as she looked out of the window and to stare at the distant sign which she read so easily just a few minutes before. She did this for only a few seconds when she promptly closed her eyes and asked for more sun treatment to relieve her pain. She was directed to practice parts of the method which helped her most, but only the method of treatment which I had given her and to do it as faithfully as she could every day until she was able to return for another treatment.

After a week of silence she telephoned me and notified me that she desired another treatment. She found out that she could not get along very well by herself with the treatment, so I gave her a special treatment each day for the next two weeks. Then she was asked to telephone me from time to time. Her reports were encouraging. She could read ordinary type and also fine type at the near point and she had no more trouble with her distance vision.

The year before she had come to me for treatment, she had given up in despair the driving of her car. She feared an accident when her vision would fail her for the distance and did not expect to drive her car again without having someone near to help her in time of trouble. She now drove many miles every day, she told me, and never forgot what I had advised her to do while she was driving, which was to shift from the speedometer to the center of the road and notice how the distant road in front of her car came toward her and finally rolled, as it were, under her car. Then again to shift from the speedometer to the center of the road ahead of her and to notice the same thing again and again. I explained to her that the roadside to her left and to her right would appear to move toward her and then move away from her if she would keep up the blinking and the shifting from the near point to the distance.

She called one day while I was out of town and told my secretary that she was helping others with the treatment of their eyes. She was a person who spent a great deal of time with poor people. The children near where she lived were fond of her and it was through them that she was able to benefit those who needed help. She purchased from my secretary enough material to help the young as well as the old folks. She purchased many sun glasses and taught mothers how to use the glass on the eyes of their children. This helped greatly in improving the sight of children, both for reading book type and also reading letters on the blackboard. She purchased test cards and took them to the Old Folks Home and those who believed that she could help them did as she directed them to do. She did a great deal of good work in helping elderly people to read book type and their newspapers without the use of glasses.

When I saw my patient again I gave her advice for helping various cases of imperfect sight and I was surprised to hear that she had benefited an old lady who had had cataract for many years and whose sight was failing fast. The vision of one of her eyes was nearly gone and the other eye was becoming almost as bad when my patient came to her and helped her. This old lady in time became able to take care of the more unfortunate ones in the home and to help in arranging personal things in their tiny rooms. This is indeed charitable work and much of it goes on in many places. If all patients who are benefited as this patient was would just help one other person with imperfect sight who cannot afford the treatment or who cannot find their way clear to visit an instructor

of the Bates Method, much more work could be accomplished.

Many errors are made by those who try to copy Dr. Bates' articles and mine and try to apply the same method to people who trust their eyes to them to be helped. It is pathetic to read the letters which come to us quite frequently with complaints about such things being done. There are some people who have a slight knowledge of the Bates Method who advertise themselves as teachers in eye training and also use Dr. Bates' name for commercial purposes. Sooner or later they are found out, but in the meantime many poor souls are made worse because of this practice.

## Question And Answers

Q - What causes night blindness?

A - It is caused by a form of eyestrain which is different from the eyestrain which causes imperfect sight with other symptoms.

Q - What causes styes?

A - Infection, which is always associated with eyestrain.

Q - Are cataracts curable without operation?

A - Yes.

Q - I am forty-nine years of age and have had to wear glasses for five years, due to gradual weakening of the eyes. Is this curable?

A - Old age sight is curable, and you can discard your glasses by following the methods as outlined in the book, "Perfect Sight without Glasses."

Q - I am practicing the methods in your book to cure myopia and astigmatism. Sometimes, for short periods, I see perfectly, then things fade away. Can you explain this?

A - This is what we call getting flashes of perfect sight. With continued practice these flashes will come more frequently and eventually will become permanent.

Q - I cannot gaze into the sun without discomfort. Do I do it incorrectly?

A - Read Chapter XVII in the book. **Do not gaze into the sun but at each side of it alternately.** In this way you not only **swing it, but allow the rays to shine on the eyes.** This is a great benefit.

Q - Can squint be cured by treatment, without glasses after an operation proved unsuccessful? Does age make any difference?

A - Yes. No, age does not make any difference.

DECEMBER, 1928

### Practice Methods

Many people have asked for help in choosing the best method of treatment for their particular eye trouble. A woman aged sixty complained that she had never been free of **pain**; pain was very decided in her **eyes and head**. She also had continuous **pain in nearly all the nerves of the body**. The **long swing when practiced 100 times** gave her great relief from pain. The relief was continuous without any relapse. At the same time a second woman of about the same age complained of a similar pain which, like the first patient, she had had almost continuously. She was also relieved by practicing the long swing. The long swing was practiced by other people with a satisfactory result.

It seemed that the swing was indicated for pain; it seemed to bring about better results than any other treatment. Later on, however, some patients applied for relief from pain which was not benefited by the long swing. Evidently one kind of treatment was not beneficial in every case. A man suffering from **tri-facial neuralgia** which caused **great agony in all parts of the head** was not relieved at all by the long swing. **Palming** seemed to be more successful in bringing about relief. Furthermore, there were patients who did not obtain benefit after half an hour of palming who did obtain complete relief after palming for several hours.

Patients with **cataract** recovered quite promptly when some special method was tried.

The experience obtained by the use of relaxation methods in the cure of obstinate eye troubles has proved that what was good for one patient was not necessarily a benefit to other patients suffering from the same trouble, and that various methods must be tried in each case in order to determine which is the most beneficial for each particular case.

## Myopia

By W. H. Bates, M.D.

Myopia or near-sightedness is usually acquired. In myopia the vision for distant objects is much less than for objects at the reading distance. Rest of the eyes and mind is the cure for myopia. Any **effort** to improve the vision always fails. How can people with myopia be conscious of a strain? This is a very important question. When methods are practiced in the wrong way or practiced unsuccessfully, a strain or effort to see better can usually be felt, demonstrated, or realized by touching the tips of the fingers lightly to the closed eyelids of one or both eyes.

Quite frequently it is difficult for people with imperfect sight to believe that perfect sight requires no effort and that any effort to improve the sight is wrong. It has been so habitual to strain, and the habit of straining to improve the sight, the memory, or the

imagination, has been practiced so long that it requires much time and patience to stop.

Recently a schoolboy, aged twelve, boasted that he could stare at one letter of a test card with his eyes wide open without blinking or closing them and for a longer time than most children could stare. He also produced a greater amount of myopia than other scholars of his school.

Mr. Priestly Smith says: "To prevent myopia we must prevent young people from using their eyes too closely and too long on near objects. This principle was established long since by the labors of Donders, Arlt, and others, and has been practically developed by Cohn and other reformers of school hygiene."

It is not true that myopia is caused by too much use of the eyes at a near point. On the contrary, near use of the eyes in a poor light lessens myopia. This fact has been demonstrated frequently with the aid of the retinoscope, while the eyes were being used too closely for long periods of time on near objects. It is difficult to understand how or why so many eminent ophthalmologists like Priestly, Smith, Donders, Arlt, Cohn, and others should have neglected the aid of simultaneous retinoscopy in solving this problem.

It was a great disappointment to find in schools that although the desks and seats were mathematically correct, myopia was not prevented any more than before. In some schools iron braces adjusted to the head and face prevented the scholars from leaning forward when doing their schoolwork. Myopia was not prevented. One eye doctor who was convinced that the braces were useless continued to use them because he said that he did not know what else to do.

In order to measure the brightness of the light of the schoolroom the light was regulated by a photometer, invented by Professor L. W. Weber. He also invented an instrument called the stereoniometer to measure quickly the amount of light from parts of the visible sky. Professor H. Cohn recommended that much money be devoted to the building of better school houses and also recommended that the school rooms be properly lighted. It was a great disappointment. No more myopia was acquired in a poorly lighted school room than in a well lighted one. A great deal more might be written describing the failures of these scientific men, who finally had to admit that they had not discovered how to prevent myopia from being acquired by school children.

The treatment of myopia which I have found best is as follows: The vision of each eye is tested and the patient is then directed to sit with the eyes closed and covered with the palms of each hand in such a way as to avoid pressure on the eyeball. At the end of half an hour or longer, the patient is directed to stand with the feet about one foot apart and sway from side to side as he reads the Snellen test card at five or ten feet. When the myopia is more than 5D. the patient may make better progress by practicing at a lesser distance than ten feet - five feet or nearer.

Some cases obtain a decided improvement in their vision in the course of about fifteen minutes. Other cases require additional methods. One of the best methods is to have the patient look directly, for five seconds, while blinking frequently, at one letter of the Snellen test card which has been committed to memory. When the eyes are closed, the memory of a known letter is usually better than when the eyes are open. By alternately regarding a letter, closing the eyes and remembering it better than with the eyes open, the vision of this letter will improve in most cases.

Those persons with a high degree of near-sightedness may not improve until the memory or the imagination of one known letter has improved to a considerable degree. It is interesting to demonstrate that the more perfectly a letter is remembered or imagined, the better becomes the sight. When a letter is remembered or imagined as well with the eyes open as with the eyes closed, a maximum amount of improvement in the vision is obtained. Some cases are benefited after other methods have failed by teaching the patients how to make their sight worse by staring, straining, or making an effort to see. When the cause of the imperfect sight of myopia becomes known, the vision oftentimes improves to a considerable degree. When myopic patients learn by actual demonstration the cause of their trouble, it makes it possible for them to improve their sight.

Myopic persons who desire a cure should discard the use of glasses permanently. Just putting glasses on for an emergency for a few minutes may bring on a relapse whereby what has been gained before is lost.

Some children with myopia may be unable to stand bright light. Many doctors prescribe dark glasses for the benefit of such cases. In my experience, the wearing of dark glasses or the use of other methods to reduce the glare of strong daylight or artificial light is an injury rather than a benefit. One of the best methods to relieve or prevent the intolerance of all kinds of light is to encourage the individual to become accustomed to strong light.

#### Sunglass

A convex glass of about 18 D. is very useful in these cases. One way to use the glass is to have the patient look far downwards while the instructor lifts the upper lid of the eyeball with the help of the thumb. This procedure exposes a considerable amount of the sclera. The strong light of the sun is now focused on the white sclera for only short periods of time to prevent the heat produced by the strong glass from causing discomfort.

This ends the routine treatment. For low degrees of myopia the results are usually very good. Imperfect sight without glasses has been temporarily or more permanently cured in a few visits.

One of the best treatments for a high degree of myopia is suggested by a few truths. All cases of myopia are temporarily cured by looking at a blank wall without trying to see. The retinoscope used at the same time has always demonstrated in flashes or for short periods of time that myopia was never continuous. When the best vision of fine print is obtained exactly at ten inches, the retinoscope always demonstrates under favorable conditions that the eye is not at this time myopic. But if an effort is made to see better by a strain the retinoscope demonstrates flashes of myopia. It should be emphasized that the strain which produces myopia is different from the strain which tends to produce other causes of imperfect sight.

**When the memory or imagination is perfect, the retinoscope used at the same time demonstrates that myopia is absent.** When a letter or other object is remembered or imagined imperfectly the sight is always imperfect and the retinoscope demonstrates that myopia has been produced.

**Shifting the gaze from one point to another point** may be done in such a way as to rest the eyes by lessening or preventing strain. **Staring or shifting with an effort always produces myopia. Moving the head and eyes from side to side produces an apparent movement of stationary letters or other objects** (oppositional movement). A complete rest of the eyes with improved vision may be obtained in this way or it may be done wrong with consequent bad results.

## The Thumb Movement

One of the best methods of obtaining complete relaxation of the eyes and mind is to **move the ball of the thumb lightly against the ball of the forefinger in a circular direction in which the circle has a diameter of less than one-quarter of an inch. Just moving the thumb in this direction does not always succeed unless one can count one, three, five, or more odd numbers, when the motion is downwards, and an even number when the thumb moves upwards.** A great amount of relaxation is always obtained by practicing the movement of the thumb against the ball of the forefinger. It is not necessary for the patient to watch the movement of the thumb in order to keep up the practice.

The movement of the thumb on the finger also activates eye movement (shifting) and the sensation of oppositional movement, activates and integrates the left and right brain hemispheres (especially when alternately done with left and right hands; left hand for a while, then right... and moving the thumb in a small counter-clockwise and clockwise circle on the finger), takes the mind away from worries, negative thoughts, brings the mind to a relaxed positive state. Relaxes mind, body, eyes, improves clarity of vision.

Thumb can also be moved a small movement on the finger left and right, up and down.

Many patients complain that when walking about the house, walking up and down stairs or when they are lying down, the movement of the thumb is not kept up continuously. Relaxation may be obtained by practicing the memory of the movement of the thumb and forefinger. Dizziness which is caused by strain of the eyes and mind has been relieved most successfully, continuously, or perfectly when an incentive is used. For example, many patients with symptoms of eyestrain, pain, or fatigue were encouraged to practice the movement of the thumb when it was found that at those times when the thumb was stationary, the symptoms of eyestrain became permanent or disagreeable. One patient found that when he walked up a steep flight of stairs that the movement of the thumb was forgotten. When he again practiced the movement of the thumb, all the symptoms of discomfort caused by eyestrain disappeared.

A patient told me that at one time a prominent physician of New York made a diagnosis of walking pneumonia and said that if he did not retire or go to bed and obtain complete relaxation or rest, he would most surely die. Too have pneumonia at that time and to have to go to bed would have been a great inconvenience because he had many things to look after, and so he practiced the thumb and finger movement. After practicing it awhile, to his delight and the astonishment of his friends, all the symptoms of pneumonia disappeared and did not return. Having a case of walking pneumonia was a great incentive to him to practice this movement of the thumb and obtain just as much rest at his work as he would have obtained if he had gone to bed.

Another patient with a case of walking pneumonia was also suffering from a high degree of progressive myopia. The movement of the thumb, besides acting as a cure for the pneumonia, was also a great benefit to the progressive myopia from which this patient was suffering. On many occasions, while walking along the street, he would notice that the movement of the thumb had stopped - he had forgotten about it. After a while he became able to remember it almost continuously with great benefit to his progressive myopia as well as the pneumonia.

Another patient was suffering from heart disease, *angina pectoris*. His eyes bothered him very much and he was very much pleased to note that when the movement of the thumb had improved his heart trouble, the myopia from which he was suffering also improved. It was a problem for him to find out how to keep up this relaxation of the nerves continuously. By practicing the movement of the thumb continuously he acquired the conscious habit. Later the conscious habit became an unconscious one with benefit to his eyes and heart.

**Myopia has many complications.** In some cases **detachment of the retina may occur suddenly without warning.** **Cataract, Glaucoma, and other serious diseases of the eyes** are often found as a complication in myopia. In **glaucoma** the eyeball becomes increased in hardness. The practice of relaxation methods usually relieves tension and brings about relief.

**Conical cornea** is a form of myopia which causes much pain and loss of vision. The cause of conical cornea is a strain or an effort to see. It can be cured by practicing the long swing or other methods of resting the eyes.

Inflammation of the iris, retina, or choroid is always benefited by the same treatment which improves or cures myopia.

The cause of myopia in school children has been discovered. Its cure is now known, and I believe that in time no child will be found wearing glasses.

Count an odd number when the thumb moves down and an even number when the thumb moves up.

## Christmas - 1927

By Emily A. Bates  
(Military Story)

Our office surely was a busy place last December and a large number of poor people were made happy at Christmas. There were not very many patients in our clinic at that time, but each patient was invited to come to the Tree and bring his or her whole family along. One blind patient, a young man, who before the World War had good sight, was so grateful for the help he had received that he wanted to give and give. He had the spirit all right and even though his pockets were empty and he could not give in that way, he gave in the best way he could.

His way was to bring other blind patients from the Blind Men's Home to Dr. Bates. It never dawned on him that there was a limit to the poor souls the Doctor could treat, while he was taking care of his regular practice. No one in the office had courage enough to stop him and so they came. His enthusiasm was so great that he himself worked more earnestly than ever in his own case. Later on he wrote an interesting article in this magazine about himself and the help that he received from Dr. Bates.

After many months of steady treatment, which was given him without any charge, he became able to see again. **Sightless eyes, made so by the ravages of war, again saw light after several years of darkness and no hope.** Other physicians who had examined him said his sight was destroyed. This was not true, for if it were, even Dr. Bates with all his knowledge of the human eye, could not have given him his sight again.

He had been gassed during the war and many operations had to be performed. All of one lung was removed. It is true that his case seemed hopeless. Operations and treatment of all kinds failed to help. The constant strain he was under, which was brought about by shell-shock and much suffering, caused depression, which could only be relieved by morphine and other drugs. After he

was treated for a short time by Dr. Bates, he stopped this bad habit, but it had to be done gradually. It was pathetic to watch him struggling to do the right thing. In trying to stop using drugs he acquired the habit of smoking many cigarettes every day. In some way he was well supplied with them all the time and preferred to smoke rather than eat. One day I talked with him for a long time and he finally promised me to smoke a smaller number of cigarettes each day. The poor fellow tried hard and won out.

His vision at the present time is 10/10. He can read diamond type at less than six inches; if the occasion warranted it, he is able to read diamond type at two inches.

**The light and heat of the sun was a great factor in bringing about a better condition of his eyes, and the added sun glass treatment, focusing the sun's rays upon the eye as the lids were raised, and also using the sunglass on the closed eyelids, was given every time he came. When there was no sun a strong light called a Thermo-lite was used for hours at a time and then the test card practice was begun.** Little by little each day the **blood circulation of the eyes became better and the nystagmus condition from which he was suffering also improved.** For the first time the eyes looked healthy to the observer and the **pupil of each eye, instead of being very small, became almost natural size.** This was not accomplished in a day but in a few years time.

Many times we are asked why some patients are cured and others not. The only answer is that if the patient will practice as earnestly and as often as the Doctor advises and does not become discouraged, a better condition of the eyes and vision occurs in time. The question "How long does it take?" is asked many times. This young man of whom I write had no such question to ask. He came with the hope of getting some relief but he was not quite sure before the treatments were started. He was willing to wait, although it was hard on him and meant patience and labor on the Doctor's part. This patient had to be led when he first came to us and now he leads others who are afflicted!

One of the elevator operators in our building had been taking daily treatment from us, slipping into the office whenever it was possible for him to do so during the day. The condition of the eye being treated was getting worse and Dr. Bates feared that in time his good eye would become affected. He had been receiving treatment for a long time before we ever knew that he was married. I guessed that his age was about 23 or 25, so I was shocked to learn later that he was indeed a married man, having been married for quite a few years, and that he was much older than I had thought. He said he had four little ones whose ages ranged from four months to four years.

How the poor fellow and his family managed to even exist on the small wages that he received is something I cannot understand. He told me that they lived in a basement where the sun seldom shone and that their greatest difficulty was to keep warm during the cold winter months. If my clinic fund had been large enough I should like to have had a ton of coal under the Christmas tree for his family, but he is only one of the many patients who receive our help, and things must be shared evenly if possible.

At no time during the year do I wish I were rich as much as I do at Christmas time. There are so many who are too proud to go to charitable institutions for help and who suffer silently and go on without the outside world really knowing their plight. When I invited our elevator operator to bring his family to the Christmas tree he was delighted and they were there bright and early. Every one of the children were spick and span and as I relieved the little mother of her precious baby and held him close to me I could tell how much pains the mother had taken day by day to keep things in a sanitary condition, for the baby had an odor about it that was as sweet as the best cared for baby ever had. The eldest child was a girl and she was quite small for her age. Next to her was a boy just one year younger than herself. In disposition he was exactly opposite to the little girl for he smiled but once as I can remember it now, and that was when he was given a toy automobile which he managed to operate all by himself by moving the wheel and seeing it run from him. The little girl hugged her doll so tightly that there was a disaster, but this was quickly corrected when she was given another doll.

Both the boy and the girl looked very much undernourished, and seemed very much in need of good pasteurized milk and lots of it. The next youngest was a sturdy little boy who did nothing but smile all the time. The Christmas tree seemed to be the most beautiful thing he had ever seen; the colored lights just dazzled his eyes and his mother had a hard time taking him away when it was time leave.

The children also received their share of candies and oranges and their arms were laden with bundles. The baby had received the usual rattle, and the mother, instead of receiving the ton of coal that I had wished she might have had, received a new warm coat instead. The only one she owned was almost in rags. She had pieced it together as much as she could and it seemed to have been a coat that belonged to someone else at another time.

Even though we are very busy in our office we make time to fulfill the duties that must be performed at that season. I was ill myself at that time and appreciated very much the co-operation I received from those at our office.

Harold, our shipping clerk, who also does other things which help in running our office, obtained the tree and also helped in the trimming of it. Miss Baron, our bookkeeper, arranged her work so that she could assist in getting things ready, and Miss Hayes, who has been a faithful assistant in the treatment of clinic patients, took the time to purchase the coat for the little mother.

Since this young married man started treatment, the condition of his eyes has improved considerably, but his improvement would be much more rapid if he could devote more time to practice.

Two sisters who had been coming for more than a year were also present at our clinic party. One was near-sighted and the other was presbyopic. The one who was near-sighted seemed to make better progress than the other. The sister with presbyopia obtained relief and better vision each time she came but we soon found out why she did not hold the better vision; she wore her glasses from time to time. This interfered with the practice and for that reason it took her longer to be benefited permanently than her sister who left off her glasses entirely. These two women, as did other women who attended, received warm stockings, besides oranges and candies. The men received ties as well as candy.

Not only eye patients, but others who had never heard of the Bates method or our clinic, were made happy at this time. While I was still under the doctor's care, my surgeon selected from his list of charity patients the two cases which he thought needed Christmas cheer most.

He gave me two names and addresses of families who received their share of the things we had to give and Dr. Bates and I went to their homes and delivered the Christmas packages ourselves.

In one of these Christmas packages was a doll slightly larger and a wee bit better in quality than those which we placed under the tree. I was told that the little girl who was to receive the doll would perhaps be a cripple for life. For her, there was little hope that she would ever walk again without braces and her condition was most pitiful. While she shared in the joy there was to give, the money used was not taken from the clinic fund but was given to me by Dr. Bates himself. The doll looked like a fairy I used to dream about when I was a little girl and I arranged her just as beautifully as I could, and the extra box which I had was filled with a large portion of nuts, fruit, and candy.

The mother of the little crippled girl was janitress of the large tenement house where they lived and we had to climb a long flight

of stairs to reach her. There was an answer to our knock at the door and there stood before us a very sad looking mother who was busy arranging her household for the Christmas holiday. We soon found out what her sadness was all about. The little girl was not there at the time but the mother explained afterwards how just a few days before, the brace which helped the child to walk was broken and could not be mended at that time because there was no money. .

It just seems as though this world is full of such sad cases and that it is necessary for those who have full and plenty to look around just a little bit and at least help one poor soul at Christmas time.

We had introduced ourselves, saying that the doctor who was helping her little girl was the great surgeon who was responsible for my life. I explained how he had performed a skillful operation and that I was on the road to recovery and that I was grateful to him. I explained that even though we had each had a group of poor people to help that there was always enough left for just one more.

When we asked for the little girl, the mother said she would bring her to us. She seemed to be in a daze, not knowing what it was all about or what we had to give the little one. The mother left the room to go to her next door neighbor where the child was staying. She soon appeared in the arms of her mother. She was a girl nine years of age, old enough to walk but not able to because of the tubercular condition she had in one of her limbs.

The little girl looked at Dr. Bates and then at me, wondering whether we had good or bad news to tell her, when her eyes spied the packages. The mother placed the little girl on the stationary tubs in the kitchen and as there seemed to be no chairs, we stood all the time.

We placed the boxes beside her and told her that Santa Claus had whispered in her doctor's ear that we should come to her. She really believed in Santa Claus and thought that Santa had not the time to come and so we came to her instead. First she opened the largest package, imagining what it might be, (and I think she imagined it was a doll). It happened to be the box containing candies, nuts, and fruits which she opened first. She was so excited about what she saw that she offered everyone in the room part of her gift. I asked her to lay it aside and then open the other package because we wanted to see whether she would like it or not. When the package was opened there was the beautiful doll with her arms outstretched to the little girl. It is impossible for me to explain the joy that came to the child, but the mother wept with joy at the thought of her child being made so happy.

From there we went to another part of the city to see a little boy. The child had been troubled with rickets since birth. He was a puny little boy who did not seem more than three years old. I was told that he was almost five but that he had not been growing very fast because of his trouble. For this little fellow we had the regular size package containing fruit and candy, and in the other box was a toy automobile. It was built like a racer and was about eighteen inches in length. He screamed with delight and was soon creeping all over the floor following the automobile as fast as it would go.

I never saw a more tidy household than this one which was in a cellar. We had to go down a steep flight of stairs to get to this little place called home and when we reached it we found the mother standing at the ironing board ironing a big wash for someone else in order to earn a few pennies. The only light and air which was received from the outside world was through one single window which was partly concealed by the staircase. She had curtains on her windows made of cheap material, but they were laundered and arranged in the neatest possible way. There was a cloth on the center table which undoubtedly was converted into a dining table at meal time. There was linoleum on the floor which was much worn but was clean and the little mother was cleanliness itself.

She was expecting another little one most anytime and she looked as though she needed rest and good food. As I watched her face while the child was enjoying what we had brought for him, I saw tears in her eyes. I asked her about her health and she said she was never better in her life. Yet I knew that she was in the first stages of tuberculosis.

I think I would know what to do with a million dollars if I had it. I would hire competent people to make a house to house canvass in the different districts of the poor of my city and I would reach the needy ones in that way. Anyway, there were a few made happy with what was contributed by Dr. Bates and those who have given to the Christmas fund. And I must not forget to extend my thanks to those who have again made it possible for us to make the poor of our clinic and others happy this Christmas time.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JANUARY, 1929

### Time For Practice

So many people with imperfect sight say that they have not the time to practice relaxation methods, as their time is taken up at business or in the performance of other duties. I always tell such people, however, that they have just as much time to use their eyes correctly as incorrectly.

**+They can imagine stationary objects to be moving opposite whenever they move their head and eyes. When the head and eyes move to the left, stationary objects should appear to move to the right, and vice versa.**

**+They can remember to blink their eyes in the same way that the normal eye blinks unconsciously, which is frequently, rapidly, continuously, without any effort or strain, until by conscious practice, it will eventually become an unconscious habit, and one that will be of benefit to the patient.**

**+They can remember to shift or look from one point to another continuously.**

**+When practicing shifting, it is well to move the head in the same direction as the eyes move. If the head moves to the right, the eyes should move to the right. If the head moves to the left, the eyes should move to the left. By practicing in this way, relaxation is often obtained very quickly, but: if the eyes are moved to the right and at the same time the head is moved to the left, a strain on the nerves of the eyes and the nerves of the body in general is produced (and central fixation, normal eye movement is prevented).**

## Astigmatism (and Conical Cornea) By W. H. Bates, M.D.

Astigmatism occurs in nearly all cases of imperfect sight for which glasses are employed to improve the vision. It is so often observed in many eyes soon after birth that many writers have stated that it is congenital and not acquired. The majority of statistics, however, show that astigmatism is usually acquired. As a general rule we may say that it always is a complication of myopia and less often of hypermetropia. In nine tenths of the cases, the astigmatism is due to a malformation of the cornea. Some writers have published accounts of cases of astigmatism produced by organic changes in the eyeball without necessarily producing corneal astigmatism.

Astigmatism frequently is recognized to be always changing. Without interference or treatment the astigmatism may increase to a considerable degree or it may become less and even disappear altogether.

The vision in most cases of astigmatism can be improved by the use of proper glasses. However, there are some forms of astigmatism in which no glasses can be found to correct the error. In regular astigmatism, two meridians of the cornea are at right angles to each other. Astigmatism often follows inflammation of the cornea. After the inflammations and ulcerations of the cornea have healed, they may leave behind scar tissue, which by its irregular contraction produces irregular astigmatism. In such cases, glasses seldom or never improve the vision, but it has been helped by relaxation methods.

When astigmatism is present, eyestrain is usually manifest. It should be more widely published that regular astigmatism, although not benefited by proper glasses, has been **improved or cured by the practice of central fixation. A perfect memory for letters and other objects is a cure for astigmatism.**

Conical cornea is usually acquired. In the beginning, the astigmatism which is produced or acquired is slight. After some years, however, the conical cornea will increase to a considerable degree. The astigmatism is so irregular that no operations on the cornea to correct this malformation have succeeded. The pain caused by conical cornea may become so severe that some physicians have recommended that the eye be removed. The treatment of conical cornea with the aid of central fixation has relieved pain in many of these cases. It is not right to ignore central fixation as a cure for conical cornea. Many eye doctors have condemned the treatment without a proper investigation.

Patients who suffered from conical cornea have consulted numerous physicians to obtain relief. These physicians too often informed the patients that there was no relief known to medical science to lessen pain and improve the vision in conical cornea. Some of these unfortunates, after obtaining the opinion of prominent physicians, have been cured by central fixation and then returned to the specialists who had previously given them a bad prognosis. In some cases I have heard that these physicians were so annoyed by the report of the cured patient that the interview was not always a pleasant experience.

The results obtained in the treatment of astigmatism of all kinds, without glasses, and by the methods I have recommended, have been very gratifying.

Some cases of irregular astigmatism suffer an unusual amount of pain in ordinary daylight. After the eyes become accustomed to the sunlight or other forms of light, the astigmatism becomes less when measured with the help of the ophthalmoscope, retinoscope, or the ophthalmometer. No matter how sensitive the eyes may be to different forms of light, gradual exposure of the eyes to the same degrees of light has benefited the patient.

In the beginning of treatment, the strength of the light used should be less than will be used later on after the eyes have become more accustomed to the strong light. It is an interesting fact that eyes which have normal vision without astigmatism seem able to stand a strong light reflected into the eyes much better than can patients whose eyes are imperfect or who have a considerable amount of astigmatism.

### Sunning

When practicing looking at the sun one should not at first look directly at it unless the eyes are normal. When becoming accustomed to strong sunlight a patient should move the head from side to side while the eyes are closed. Many people have observed that when looking at distant electric lights, the lights observed were imagined to be moving. When the lights did not appear to be moving, movement of the head and eyes from side to side would produce an apparent movement of the distant light. Patients who were able to look directly at the sun without any discomfort whatever volunteered the information that looking at the sun was not disagreeable, providing one imagined that it was moving from side to side. Shift the eyes left and right, side to side of the sun and move the head/face with the eyes. Shift top and bottom, circle the edge of the sun counter-clockwise and clockwise.

The treatment of astigmatism is a matter of importance because for many years no methods of treatment were at all successful. One of the most successful methods of treating astigmatism is to encourage the patient to **remember, imagine, or see letters of the test card perfectly**. The patients are encouraged to commit the card to memory. When letters or other objects are memorized perfectly, the astigmatism always becomes less until it disappears altogether. This is a truth to which there are no exceptions and suggests a method of treatment which should always prevent or cure imperfect sight produced by astigmatism.

With the consent of the principal of a large school in New York City, I placed a Snellen test card in all the rooms of the school. The principal asked me how I could prevent the pupils from memorizing the card. She was told that it was planned to encourage the pupils to memorize the card, because letters on the Snellen test card could be remembered, imagined, or seen best after they were memorized. She was also told that the teachers could help materially in the prevention or cure of astigmatism.

Looking at familiar, clear objects relaxes the mind, eyes, keeps the vision clear at all distances.

The principal shrugged her shoulders and said that she would not be a party to any such foolish plan and that she would not allow any of her pupils to use the Snellen test card for any purpose whatever. She told some of her friends, however, that she was going to put the card up and encourage the children to memorize it and then prove that she knew more than the Doctor, namely that the Snellen test card memorized was of no benefit whatever in curing astigmatism. She also admitted that she did not know the first thing about astigmatism and did not want to know anything about it.

At the end of three months I called on the principal again. A friendly teacher told me that my enemy was gloating over the prospect of finding out how little most doctors knew about the eye. She seemed very glad to see me and shook hands and smiled and said that they were all ready to test the sight with the Snellen test card and find out how much good had been done by its use.

First she examined the sight of all the children and compared it with a record that she had made previously. She was not satisfied with the result and asked another teacher to test the sight of the children and report. Quite a number of teachers were present at this second examination as well as at the first and the number of visitors increased until there were more teachers than there were pupils. Everyone was anxious to know the result of the trial.

It was a shock to all the teachers who tested the sight of the children to find that the vision of every pupil had improved and many

children wearing quite strong glasses for the improvement of astigmatism had read the card perfectly without glasses. My enemy was not satisfied; she thought there must have been something queer in my cards so she obtained some strange cards from other teachers and it did not add anything to her peace of mind to find that the vision of the children tested with the strange card was much better than when my card was used.

Some patients with astigmatism complain that when they first awaken in the morning their eyes are under a much greater strain than in the afternoon. When such cases are examined with the aid of the retinoscope during sleep, they are found to be suffering from a great strain. The strain is not always apparent; the patient does not always know when it is present. Children are sometimes great sufferers from eyestrain during sleep. Many others have been advised to watch their children during sleep and if they believe the child is straining his eyes, the child should be awakened and taken out of bed. (The mother can tell that the child is suffering from eyestrain if the eyelids twitch and if different parts of the body twitch). The mother should then have the child practice the long swing for a few minutes or longer.

One man came to me suffering great pain almost constantly, which was not relieved by the use of glasses for the improvement of his astigmatism. He was told about how eyestrain during sleep can produce astigmatism, and of the symptoms of astigmatism which were pain, fatigue, and dizziness, and also how much benefit is obtained by practicing relaxation methods more or less frequently during the night. He had no one to call him during the night, so he gave orders to a clerk in a nearby hotel that he should be called by telephone every two hours during the night. When he was awakened he would practice relaxation methods. The relief was considerable and there were mornings when he testified that he was rested and had no symptoms of eyestrain at all. It was a great comfort to him to get rid of his headaches and the agony of pain which he described as being in his eyes and had been there many years.

One patient, a boy about twelve years of age, memorized the Snellen test card so that he could read the whole card of fifty-three letters in less than ten seconds. It was discovered that with the improvement in his memory, his vision for a strange card was also improved and his astigmatism became less and finally disappeared entirely.

#### Staring

Many people are unable to stare for any length of time because staring is painful, disagreeable, and produces fatigue. However, a boy ten years of age had practiced this staring and had acquired much skill; he was able to outstare any boy or girl in his classroom. He then went to other classes and challenged each boy and girl in those classes to a contest to find out which one could outstare the other. In order to excite their antagonism he called them names, so they stood around him and attempted to outstare him, but he, being in good practice, came out the winner.

The boy's teacher noticed that after some of these staring contests, his eyes became quite inflamed, and his vision was unusually poor. His parents took him to a competent eye doctor who discovered that when he stared he produced a considerable amount of astigmatism. The doctor wanted to put glasses on him but the boy objected; he did not want glasses on because that wouldn't be fair to the others. The doctor said that if he did not get well he would have to wear glasses, so the boy made up his mind to stop staring.

Anyone who can stare and strain to an unusual degree is able to relax the strain. It is interesting to demonstrate with the aid of the retinoscope that staring may produce a very high degree of astigmatism, but always after the staring is stopped the vision improves very much and the astigmatism becomes less. In short, it is more difficult to produce astigmatism than it is to cure it.

A man, aged sixty, suffering from astigmatism, had great difficulty in practicing central fixation, shifting, swinging, and the long swing. After four visits to my office he said that he had obtained no relief from his depression, his headaches, or other symptoms of astigmatism. He was advised to sit in the waiting room and try to do nothing whatever. At the end of this time his vision was tested and found to be normal. He was unable to practice relaxation methods because he made too great an effort, but when he did nothing and made no effort, his vision improved.

## Chronic Iritis Relieved By Treatment

By Emily A. Bates

In Santa Monica, California, there lives a grateful patient who was cured of iritis and near-sightedness by the Bates Method during my stay in the West. He held a responsible position in one of the large banks there and he needed his sight most of all at his work. Two years previous to the time I saw him, he suffered an attack of iritis which caused much pain and discomfort most of the time. The usual drugs were used to relieve the pain but at times even these gave little relief. At the advice of some eye specialists he put on dark glasses and these enabled him to go out in the bright sunlight, something which he could not otherwise have done. Most patients who suffer from iritis cannot open their eyes at all while they are in a bright light. Dark glasses relieved the pain somewhat but they did not cure his trouble. He obtained Dr. Bates' book, "Perfect Sight Without Glasses" and tried to apply the method by himself and then later came to me.

I wanted to be sure about the diagnosis which had to be made before I started treating him, so I sent him to an eye specialist who was taking care of my diagnostic cases. After my patient had called on this specialist for an examination of his eyes, he returned to me with the statement from the physician. It was purely a case of chronic iritis and the doctor was interested to see how the patient would get along under my care.

In March, 1927, the patient paid his first visit for treatment and he came alone. His vision for the test card with the right eye was 15/40 and with the left 15/50. The letters were blurred and indistinct and he lowered his head considerably while trying to read. When he was directed by me to hold his head straight while reading the card his eyes closed tightly and he did not have the ability to keep them open long enough to read even one letter at a time.

I handed him the Fundamental card and he said that at no distance, as he held the card farthest away from him and as near to his eyes as he could get it, could he read any of the type. After closing his eyes again for a short period of time he read Number 3 as he moved his body from side to side while sitting comfortably in a chair. By shifting from the white spaces on the card of the microscopic type that I gave him to the white spaces of the diamond type and then to the white spaces of the Fundamental card he read as far as Number 5 of the Fundamental card. (Looks directly at the print when reading it - central fixation.)

I had a case similar to his about four years ago, a case in which it ordinarily takes from four to six weeks to cure the pain alone. This patient was entirely relieved of pain, and her sight, which formerly was not normal, became so at the same time the iritis was

cured, which was inside of two weeks. She had an acute attack of iritis before I saw her, which lasted for several months. A physician friend of Dr. Bates and myself saw this case while she was under treatment and while she was still suffering intense pain. When he examined her, at my suggestion, his opinion was that she could not possibly be cured within six or eight weeks at least. After she was cured, the case was reported to this doctor, who was amazed at what had been done for her. This case came to my mind instantly when the patient mentioned above visited me.

I noticed that he did not sit quietly while he was palming and thought that he was not getting any benefit in that way, but when I suggested it to him, he said that he liked to keep his eyes closed, but that covering his eyes with the palms of his hands seemed to bother him. He was encouraged then to keep his eyes closed for a period of half an hour while I was planning a regular routine of treatment for him.

Before he opened his eyes to read the card again, I asked him to describe parts of his daily work at the bank. It was interesting to hear him describe the difference between the notes that passed through his hands. He explained to me how a counterfeit bill is discovered by examining it carefully. Because of the pain he had been suffering for a long time I refrained from joking in any way, which I sometimes do if the patient is agreeable. There usually comes to my mind some funny incident which occurred while treating someone and I like, if possible, to change the subject from pain to something else, especially while the patient is palming.

This patient, however, did not make me feel that way in the beginning because of his reserved manner and also because of his pain. It was quite unexpected then to have him answer me in a funny way and tell me of something which he could remember most of all and which was constantly before him while he was at work. He said it was a nice, shiny thing with a black hole at one end and he made me laugh when he said it was a revolver, which was only introduced on rare occasions when there were suspicious people a little too close to him. This was something new to me and I had not expected it. His hearty laugh was most relaxing not only to him but to me also.

I told him that my sight was apparently normal but I feared that if I came in close contact with his revolver as I came near his window, I was sure that I would become myopic or acquire a cataract or something else. As quick as a flash I asked if he had any pain and as quickly he answered me saying "No, I haven't any discomfort whatever just now."

Immediately he was told to open his eyes and to read the card, which he did without squeezing his eyelids together as he did before. (Squinting) His vision improved to 15/10 and he said that the letters were clear. I am anxious for those who read this not to misunderstand me. He was not cured by any means nor was his vision permanently relieved right at this time. His vision improved and his discomfort and pain were relieved because his mind was relaxed. I thought this was a good beginning for the first treatment and told him so. He agreed with me and promised to practice as I directed him to do until I could see him again.

Financial difficulties prevented him from coming to me every day, which he should have done and which would have made the cure of his eyes permanent in a much shorter time. I surprised him the next day by telephoning him and offering to help him over the telephone. I happened to call him at a busy time, so the discussion was short and took less than ten minutes of his time and mine. He wrote me a letter in a week's time telling me how much good I did him in those few moments.

As he talked to me at that time he stood before his telephone which was fastened to the wall. Just before I called him he had had an attack of pain and explained that all the window shades in the room where he was had to be drawn because the light caused so much pain. My advice was to **place himself before a bright electric light as close as he could stand the heat and, with his eyes closed, move his head slowly from side to side in order that all parts of the eyes would receive the benefit from the light and heat.**

I held the receiver while he did this and he soon came back to the telephone to tell me that the pain had gone and that he had raised the shades and was able to **look out into the bright sunlight from one of the windows without feeling any pain.** I advised him to write down immediately the things that helped him most and to practice these things, no matter how short a time he had each day. I told him to **sway his body from side to side** as he held the receiver and was talking to me and to **blink his eyes** with the movement of his body. This gave him some relief also. From time to time I advised him by letter and also by telephone.

In May of the same year my patient came again and this time he brought his wife, asking for permission to have her watch the treatment so that she could help him at home. I was glad that he brought her because I knew when I saw her that she would be a great help to us both. The instructions I gave her at this second visit were carried out by her and by the patient during the summer months while they were vacationing in the mountains. Toward the end of the summer, they both came to visit me and the condition of my patient's eyes as well as the expression on his face indicated no more trouble. I tested his sight for fine print and he read the Fundamental card, by W. H. Bates, M. D., through to the end, holding the card slightly farther than six inches from his eyes. His vision for the distance was also normal, 15/15 with each eye separately.

His wife had told me that at times he suffered agonies of pain during the night after he had slept for a few hours. As long as she could remember, she said, he had never slept quietly all through the night. He was troubled with nightmares and he also had insomnia for many years, and at such times he would sit up for hours and smoke his pipe in order to while away the time until daybreak. For quite a few years, Dr. Bates has been benefiting patients by having them do the **long swing 100 times early in the morning and 100 times just before retiring.** I remembered this and advised my patient to try it and let me know in a week's time whether he had any success with the swing or not.

Three days later I received a message over the telephone saying that since his last visit to me he had faithfully practiced the long swing 100 times in the morning and 100 times at night as I have advised. The results were good. He slept all through the night without waking up and without tossing about as he had been doing for so long a time. His wife remained awake purposely to watch the results and at other times, being a light sleeper, she would wake up to find her husband in the same position as he had placed himself before going to sleep.

My patient purchased a **sun-glass** from me and I directed his wife how to **use it on his closed eyelids as he sat in the warm sunshine on his patio.** In the beginning, when I first used the glass upon his closed eyelids he resented the treatment very much and the strain he was under while the sun glass was being used caused a considerable amount of tearing of the eyes. The patient feared the outcome of such treatment, but while the condition was made worse temporarily for a short period of time, it proved to be the best treatment in permanently curing his trouble.

Every day he became more accustomed to the **sun-glass treatment** and all during the summer while he was on his vacation, the sun treatment was given more frequently each day. A tent was used so that his body as well as his eyes could receive the sunshine. This proved to be a **benefit to his general health as well.** When he returned at the end of the summer, I was much surprised to

Man runs with his dog, sees the dog's tail wagging above the tall grass in the distance. Seeing the tail wag helps his eyes shift, use central fixation and helps him to see objects swing, move opposite to the movement of his head, eyes.

see a change in the expression of his face. **The sclera or the white part of each eye was as clear as mine and his eyes were wide open in a natural way.**

He told me of the different things he tried each day for relaxation of the eyes and mind. **His wife would read to him while his eyes were closed and he would construct mental pictures of what she was reading.** At other times he would **run and race with his pet dog, who could run much faster than he could and the dog would get quite a distance away from him.** However, **the wagging tail that he could see above the tall grass would always help him to find his pet and to run again with him.** He said the **wagging tail of the dog helped him to see things move opposite to the sway of his head and eyes.** He said he had not realized how much of a strain he had caused his wife, who was at one time a carefree girl with a jolly disposition, but through his suffering had become a very serious person.

The gratitude of both my patient and his loyal wife was most profound and they have since then proved loyal friends to "Better Eyesight." Many patients have come through them for treatment.

### Correspondence Treatment

Many letters are received from people in various parts of the world who find it impossible to come to New York and who believe that something might be done for them by correspondence treatment. I do not advocate correspondence treatment as a general rule, as the results are uncertain. There is always the possibility that the patient will not practice correctly the things which he is told to do.

If a patient has had one treatment at my office or at the office of one of my representatives, it is possible to treat that patient more intelligently through correspondence.

Some years ago a gentleman living a thousand miles from New York called and asked if anything could be done through correspondence for his wife who was bedridden and suffering with an agony of pain in her eyes. He described all her symptoms to me and gave me her last prescription for glasses. He was told that if he would take the treatment in my office, and so learn how to treat his wife, it would be possible for him to aid her intelligently when he went home. He did this and after taking several treatments, returned. He wrote me later saying that his wife was almost cured.

When my book, "Perfect Sight Without Glasses," is read carefully, those things which are not understood may be cleared up by intelligent questions, which I am always pleased to answer. I do not consider this as regular correspondence treatment.

## Squint

By W. H. Bates, M.D.

In **SQUINT**, the right or left eye may turn in toward the nose while the other eye may be continuously straight. When the straight eye is covered with a screen, the squinting eye usually becomes straight temporarily. There are several types of squint, one of which is called divergent squint, in which one or both eyes may be turned out to a greater or lesser degree. In another type, vertical squint, either eye may be turned upwards, downwards while the other remains straight. In rare cases both eyes may be turned above the horizontal meridian, or the eyes may be turned below the horizontal meridian. Squint is usually acquired soon after birth, but a great many children do not squint until they are three or four years of age or older. Rare cases will acquire squint when past fifty years of age.

The eye which turns in different directions habitually usually has imperfect sight which is not always corrected by glasses. The vision of the squinting eye when imperfect is called **amblyopia**. Amblyopia means blindness without any cause which can be seen or described by the attending physician. The best treatment is to get rid of the strain which is always present. One of the early writers on squint, its treatment and cure, said that the blindness of squint was a condition in which neither the patient nor the doctor could see anything wrong with the eye. Lack of use of the squinting eye lowers its vision and, also the brain turns of the image from the squint eye to remove the unbalanced vision, incorrect, double... image produced by the squint eye.

Amblyopia is a condition of imperfect sight in which the retina, the optic nerve, and other parts of the eye show no organic change. The blindness of the squinting eye may be so great that the patient may not be able to see even daylight. These cases may develop absolute blindness with no perception of light and yet have been cured by treatment, by doing away with the strain. It should be emphasized that eyestrain has been frequently found in all kinds of squint and this eyestrain is sufficient to lower the vision until even light perception is lost. Palming, shifting, central fixation, improving the memory, imagination, relaxing the mind, eyes, equally activating and integrating the left and right brain hemispheres and other Bates treatments cures amblyopia, squint.

Eyestrain, which is a mental phenomenon, is capable of producing in the eyes organic changes which are sufficient to cause total blindness. By relieving the eyestrain the vision always improves until it may become normal. The men who for years have published in books or in various periodicals that the blindness of squint cannot be cured should investigate the facts by the aid of modern scientific methods, which prove that the **blindness of squint is not very difficult to cure**.

In searching through the literature for facts I found some very queer statements. One very prominent ophthalmologist published in a medical journal the statement that the blindness of squint could not be cured. In the very next sentence, he gave the history of a **patient born blind with amblyopia, squint, and cataract who obtained perfect sight by treatment**. The patient was forty years of age. The cataract in both eyes was operated upon successfully. The patient had never seen letters and could not read a newspaper, even with small size headlines. (Misprint? should be large size headlines or does it mean simple headline with only few words?) He could see flowers of different colors but he did not know the names of any of them. He was taught the names of familiar objects that he saw and in a very short time his eyesight seemed to be normal.

The eye surgeon called attention to the fact that the imperfect sight was improved to the normal by treatment of the eyestrain. The surgeon described how the cataract was removed and how the patient became able to read by being taught by school teachers who discovered the difference in the vision of each eye. The eye which habitually turned in had very imperfect sight. The vision of one eye and later both eyes improved to the normal by eye education which relieved or cured the eyestrain. Some of the readers of this doctor's article asked him embarrassing questions and he finally stated that he now believed amblyopia could be cured by eye education. He had unconsciously practiced my method. The amblyopic eye was blind from eyestrain and vision was restored after the eyestrain was relieved by relaxation

Patch over straight, normal eye. Using crossed eye to improve movement, clarity of vision in crossed eye.

Practice of switching, shifting, central fixation must be done with the eye that needs improvement and also with both eyes together, then one eye at a time; strabismus eye, then the other straight/normal eye, then strabismus eye again, then straight eye... then both eyes together again to keep both eyes straight, clear vision, working together, both left and right brain hemispheres equally activated, integrated, whole brain functioning, working with both left and right eyes, all eye muscles.

Double image of the candle flame. Images are correct, at an even height with each other - this indicates the eyes do not have an upward, downward strabismus. Eyes/pupils are at an even level with each other.

### Steps to correct crossed, wandering eyes. Use the eye patch.

- + Improve the vision to the best possible in the left and right eyes by switching, shifting, central fixation. memory, imagination, relaxation... on objects at close, middle, far distances using both eyes together, one eye at a time, both eyes together again.
- + Then, practice seeing double. No eye patch. Use both eyes together.
- + Imagine seeing double vision at 3 ft., 10 ft., 20 ft. and farther; Example: Place a candle at 20 feet. Light it.
- + Imagine see a double image of the candle flame.
- + Eyes open: imagine seeing the two candle flames (double image) with the images 5 ft. apart. If the eyes actually see this, its good.
- + Eyes closed - imagine seeing the double image, two candle flames 5 ft. apart in the mind, imagination and then:
- + Imagine the flames move closer together, farther apart, closer together...
- + Then, with the eyes open and then closed - remember, imagine and see the two flames one ft. apart. (Candle still 20 ft. away in the distance.)
- (If the two left and right images are at uneven heights-imagine the double image and imagine the left and right images are at an even height with each other with the eyes open, closed, open. (See other diagram.) This corrects eyes that wander up or down, that are not even with each other, and helps correct imperfect convergence, divergence, brings both left and right eyes at a even level with each other. Look to objects in the distance beyond the candle and up close before the candle to see two flames and check for even height. Practice until they are even.)
- + Next: candle still at 20 ft. See the double image. (Cross the eyes to see this or look at a close object.) Remember, imagine and see with the eyes open, closed, open the double images 1 ft. apart and then:
- + Imagine the images correct:
- Right eye sees its image on right side of visual field.
- Left eye sees its image on left side of visual field.
- Then: Relax and let the two images move closer together and merge into one image of the candle flame. Look directly at the candle flame. Shift on it part to part.
- Practice repeating this, moving the images farther apart, closer and merging into one then shifting on it.
- + Next: now use effort and make the image of the right eye move over to the left side of the visual field and the image of the left eye move over to the right side of the visual field.
- + Then: let the two images move toward each other, and merge together into one image of the candle flame. See Dr. Bates full directions.
- This last step may only work if the person has a wandering, crossed eyes/eyes. It can be done by normal eyes without effort or strain by looking at a distance beyond the candle when the candle is placed closer. (See other diagrams with the tree in the distance and angel up close with the candle at the middle distance.) Compare to the Bead String Exercise popular in Natural Vision Improvement books.
- This last direction by Dr. Bates I find hard to understand. I have normal eyes and find it impossible, too straining to do this last step of seeing the images incorrect on opposite sides but I can easily do it by moving the candle closer and looking beyond it to the distance. Some people with strabismus can move the eyes in all different directions and this may make them capable of doing this experiment the other straining way with benefit by then realizing and releasing the strain and letting the eyes move to a normal position. Or, Dr. Bates meant for the person to look farther into the distance with the candle closer to produce the effect of the images from the left and right eyes to cross over to opposite sides of the visual field. The bead string, switching, shifting on objects at close, middle, far distances with both eyes, one eye at a time, and both eyes together again also helps to correct crossed, wandering eyes without feeling strain, effort. This also improves accommodation, unaccommodation which works with convergence, divergence and each of these improves the other.

treatment.

To obtain improved vision with the good eye covered, one patient wore a shade over the eye which was straight, while the vision of the squinting eye was benefited by eye education. At the end of a few months it was found that the eye which formerly had looked straight was now turned in. At periodic intervals the right eye became straight while the left eye turned in. After covering the good eye with a screen, the vision of the other eye became straight. It required several months before both eyes became straight at the same time and each had good vision. Eye muscles, eyes learning to work with Brain, left and right hemispheres.

### Practice Imagining, Remembering, Creating, Seeing, Controlling, Moving Double Vision/Images to Cure Crossed, Wandering Eyes.

In the cure of squint without operation it is important that the instructor become able to practice a few fundamentals in order that the patient may be more readily taught to do the same.

In all cases of squint, double vision should be imagined at three feet, ten feet, twenty feet or farther. It often requires considerable practice before the teacher can produce double vision. **The best possible vision should be obtained in each eye before much is attempted to cure the squint.**

Most children can see or imagine double vision by practicing with a lighted candle or other object. In some cases two candles are imagined five feet apart when one is practicing with a candle at twenty feet. By closing the eyes and resting them, it is possible for the patient to demonstrate that two objects appear to be five feet apart, by the use of the memory. Images five feet apart can be imagined to be either more or less separated.

The eyes of most people are capable of remembering, imagining, or apparently seeing two images one foot apart at twenty feet. If the objects are on the same level they can usually be controlled much better than when one is higher than the other. In a case of convergent squint it is quite easy to imagine the two objects as they should be imagined; the image of the right eye should be to the right, the image of the left eye should be to the left. When the two images are on separate levels it is well to practice so as to attain the two images on the same level. This makes it easier to control the two images in other directions.

By alternately regarding the images without effort or strain, they will approach each other until they touch, overlap or become fused into one object. Then more practice should be done with the object of obtaining control of the location. By some forms of effort the image of the right eye may be forced to the left while the image of the left eye may be forced to the right. This should be practiced for half an hour or longer, forcing the images seen by each eye to appear crossed. At first the images are not controlled; they may cross and separate a wide distance, three feet, or even six feet.

It is well to practice the production and control of the crossed images in cases of convergent squint in which the image of the squinting eye does not always reach a position on the opposite side of the image seen by the right eye. It is interesting to observe how quickly two images can be made to cross, to approach each other, to touch, and to merge into each other and form one. By practicing the production of crossed images a considerable time each day the crossed images become consciously, habitually, or permanently crossed (merged into one) when a cure is obtained.

A girl, aged fourteen, had vision of the right eye of 3/200 while that of the left eye was 20/10. When she was two years old the tendon of the muscle which turned the right eye inwards was cut. The result was variable. Sometimes the eye turned in as before, but there were periods when the right eye was straight. Relaxation methods were employed daily with success and the squint became less when the vision improved.

The method which helped the most was to improve the vision of the amblyopic eye by remembering or imagining perfect sight of one letter of 20/10 with the eyes alternately closed and open. The vision of the right eye improved until it became 20/10. The patient was also encouraged to imagine fine print six inches from the right eye. When she succeeded in improving her vision for twenty feet and later her ability to read fine print at six inches, the squint disappeared. Both eyes focused on one point at the same time.

Left (normal eye) covered with patch. Using the right, less clear vision, squint eye to improve vision in that eye.

+Shift on and remember, imagine and see a letter on the 20/10 line on the eyechart perfectly clear with the eyes open, then in the imagination with the eyes closed, then with the eyes open again. Practice as described here:

**Eyechart**  
Practice with the chart at close, middle and far distances until vision is clear in both eyes at all distances. Practice with both eyes together, then one eye at a time, with the eyepatch (more practice with the eye that needs vision, movement improvement,) then with both eyes together again.

Read fine print with both eyes, then one eye at a time, (and a little more practice with the squint eye), then with both eyes together again.

The appearance of the double candle flame is caused by the the same principles that cause the double beads to appear on the bead string. See book; Do It Yourself - Natural Eyesight Improvement, Switching chapters.

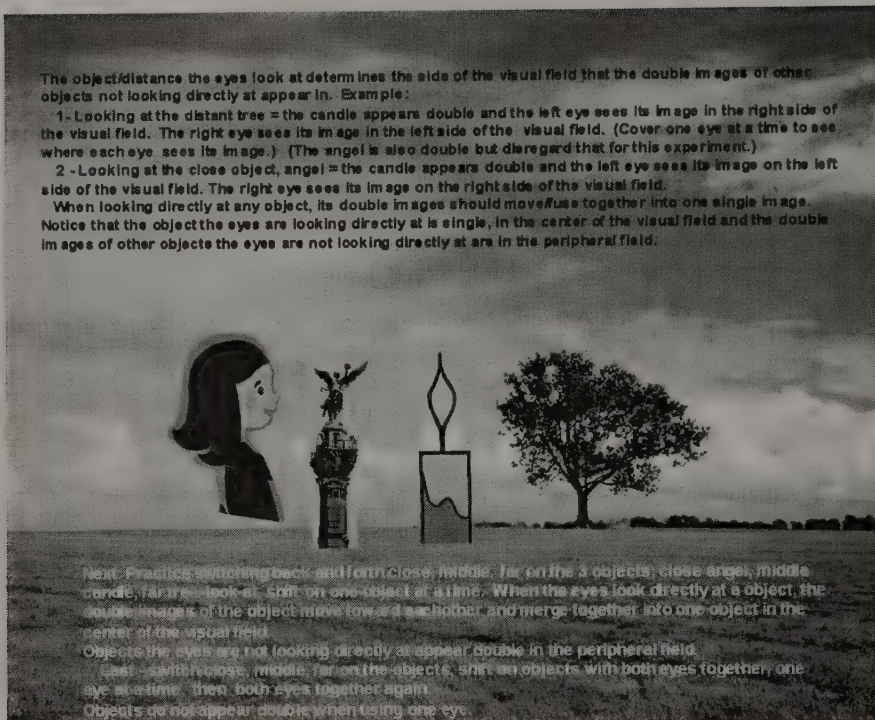

## LOOKING AT BEAD 1 RED - CLOSE

Cover one eye at a time to see which eye sees which side of the double image in the peripheral field.

The image that disappears is the image produced by the eye that is covered, not in use.

If one image is light, blurry, less clear - the eye producing that image needs vision improvement. The blur can alternate in the left and right eyes depending on the distance the eyes are looking at. Example; looking at the candle. Distant tree is double. Left image of the tree is less clear, lighter. Right image is solid, clear. Cover the left eye and the left image disappears=left eye is producing the blurry image. The left eye needs vision improvement at far distance.

Now look at the distant tree and observe the double images of the candle. Are they equally solid, clear..? Which eye is producing which image of the candle?

#### Central Fixation Cures Squint

**CENTRAL FIXATION** or seeing best a letter or other object regarded (object the eyes are looking directly at, in the center of the visual field) while all other points are seen worse, is a successful method of curing squint and improving the sight in cases of squint.

A very remarkable patient, a girl aged eight, was treated more than fifteen years ago. The vision of the right eye was 2/200 while that of the left eye was 10/200. The right eye turned in most of the time. The vision of the left eye was improved without glasses by alternately resting the eyes.

An attempt was made to teach her how to see best where she was looking. She very soon acquired the ability to practice central fixation when the larger letters were regarded. The child became much interested when she realized that her eyes felt better, while the vision and squint improved. She practiced central fixation on smaller letters and other objects. The strain which was manifest by the contortions of the muscles or her eyes, face, and other parts of her body disappeared. Her voice became more musical with the improvement of her vision and the subsidence of the squint.

**It was remarkable how well she became able to practice central fixation on very small letters and other objects. She would hold a glass slide on which a small drop of blood was mounted, and claim that she saw the red cells, the white cells, and other minute particles with her right eye while the glass slide was pressed against her eyelashes. She was able to read each letter and period in photographic reductions of the Bible, by central fixation.**

Many people have complained that they could not see black or imagine a black period for an appreciable length of time. This patient, when palming, stated that black was seen and that with the aid of central fixation even the smallest black periods were seen but they were always moving a distance nearly equal to the width of the period. An effort to see always failed. Distant objects were seen as far off, by central fixation, as it was possible to imagine them.

**This patient was able to produce at will, consciously, and continuously, internal squint of the right eye with the left eye straight or could keep the right eye straight while the left eye turned in.**

## Don't Be Afraid

By Emily A. Bates

I have heard many patients who came for first treatment say "I am afraid." This remark is usually made when we suggest that the patient should stop wearing glasses immediately in order to receive a permanent benefit. I have known of patients who only had a minor defect of vision who were uncomfortable at work unless they wore their glasses. Those who have worn glasses for just a few years and received little or no benefit while wearing them would go to many doctors with the hope that they would obtain the proper eye glasses which would relieve them of their tension and pain.

Most of our cases are chronic and they appeal to Dr. Bates or to me to help them when all others have failed. I hope to be able to reach such cases through this article, and if what I am trying to explain will be of just a little help, it will be worth while.

A patient came to us recently who had traveled three thousand miles to see the Doctor, but when he was told that he could not possibly be helped unless he removed his glasses at once and did not wear them again, he became panic stricken and wept. Doctor is at a loss sometimes when such things happen and he usually appeals to me for assistance. Encouragement is not always enough for a stranger who comes to us not feeling at all sure that he is in the right place, even if he has been well recommended. He wants facts and he wants to meet others who have gone through the same ordeal that he is expected to go through.

Fortunately there was a patient in the next room who overheard the conversation I had with this man. He came to the door of our room and asked if he might talk to this patient and tell him of his own experiences. He explained how he had traveled many miles to see what Dr. Bates could do for him. He had worn glasses many years and they helped him for some time, but even with glasses on, his vision became worse for the near point. He did not need glasses at all for the distance but at the near point he was unable to distinguish large objects clearly enough to know what they were.

When our new patient first met Dr. Bates, who in his quiet way started right in to treat him, there was a fear in his heart that he had perhaps made a mistake in coming. He wanted things explained to him. He was afraid that sooner or later his vision, even for the distance, would become impaired and that in time blindness would surely overcome him. He was afraid. The older patient explained to this man how Dr. Bates had kept him for two hours in his office during the first visit and how, after he left the office, he was able temporarily to read finer print than newspaper or book type. He wanted to save time and expense and did not come again for several days, which was a big mistake, and he realized that it was.

He could not practice so well at home by himself and he became discouraged and put on his glasses again. When he called for another appointment he had to go right back to where he started from. He had wasted two precious hours and the fee besides, because he had been afraid. During the second treatment, however, he was able to read finer print with less difficulty than he had during his first treatment. This encouraged him very much. This time he made no promises to the Doctor that he would not wear his glasses, but he was determined that he would not. He explained to our new patient how some days he could not practice as successfully as he could on previous days, but he kept right on remembering what the Doctor had directed him to do and he did it. Two weeks of daily treatment have given him almost normal vision. All he needs now is a little more knowledge of what he has to do when a relapse comes and then he will be rid of glasses for all time. This talk with the other patient helped Dr. Bates to manage his new case more easily and with more confidence in the Doctor, I feel sure that the patient will win out.

Not long ago I had a patient who came from Chicago to be relieved of a swelling eyelid condition and a burning of the eyes whenever she read for an hour or longer, or when she did a little sewing of any kind. Even threading a needle was painful to her with her glasses on. She had received treatment from one of our students in Chicago with some benefit. She assured us that her lack of complete success was not the student's fault, but her own in not understanding just what to do first for the relief of pain and discomfort.

After Dr. Bates had examined her eyes with the ophthalmoscope he found that her condition was mostly mental; she strained hard to see the print of the book or newspaper she was reading. She did not realize that she was staring at the letters instead of looking at the white spaces directly below the sentence she was reading. (As mentioned previously; looking at the white spaces when reading the letters is not advised by modern Natural Vision Improvement teachers, but; taking a break and looking at the white spaces, blinking, shifting, looking to the distance occasionally to relax the eyes when not looking at/reading the print is beneficial.)

All proof readers or those who are obliged to read in a poor light can read without strain if they do not stare at the print and if they remember to shift their glance to the text and back to the white spaces below the sentence they are reading. (And look to the distance, shift on distant objects occasionally.) Public speakers often make mistakes in reading to an audience, even if they have beforehand studied the subject of their paper so well that they could almost say it by heart. They become unable to memorize and become mixed up in what they are saying or reading because they unconsciously stare at the print in order to read it, mostly because they are afraid they may make a mistake. As soon as we teach them to dodge (avoid staring at) the print and pay more attention to the white spaces between the lines of type (or look to distant objects if the eyes start to feel tired), they are soon cured and no longer need glasses to help them.

A few months ago a mother brought her daughter from high school where they had noticed that she was squeezing her eyes almost shut in order to see the writing on the blackboard. It is unusual to see a young girl sixteen years of age with many wrinkles in her forehead. It was so noticeable to others that she was soon made unhappy because of this. The authorities at the school that she attends notified the mother that her eyes must be examined for glasses. Neither her grandparents nor her mother or father had ever worn glasses and it was a shock to the mother to think that the daughter would have to wear them. The girl became depressed and unhappy and felt, as did her mother, that there must be some way in which to relieve her trouble so that she would not have to wear glasses.

As Dr. Bates has so little time to explain the reason why, he often calls upon me to do the talking if it is necessary, or even when it is not necessary. I thought I had convinced the mother that her daughter would not have any more trouble with her eyes if she would learn to do what we had told her, and that if she would practice every day the treatment we would outline for her while at school and in her home, she would enjoy good sight and not need her glasses. I was much surprised when the mother answered me like this:

"How can you possibly understand the discomfort that patients have who need glasses or who ought to wear them when you have never had imperfect sight yourself?"

## Emily Lierman/Bates Experience with Eyeglasses and How Dr. Bates Cured her Vision

I forgot myself and laughed at the remark and then I explained to the mother how for thirteen years I had worn glasses to do my work. When it was first noticed that my eyes were not functioning correctly and that I was making mistakes in my work, which was matching colors and combining them, my employer suggested that I should be examined for glasses. He explained to me that the mistakes were minor ones but that from day to day I would perhaps make more serious mistakes and I would lose my position.

That was a shock to me, and immediately I went to the New York Eye and Ear Infirmary at 13<sup>th</sup> street and 2<sup>nd</sup> avenue, where I was placed in a dark room after drops had been applied in each eye. I explained to this mother how I had been forgotten and left in that dark room much longer than was necessary and it seemed hours to me. The thoughts that went through my mind were mostly fearful ones. I was afraid that my eyes were going back on me. The doctors at the infirmary did not explain a thing to me before they gave me the drops.

The eye glasses which were fitted for my eyes suited me very well for two years and then my eyes began to trouble me more than ever and the glasses had to be changed. I did not go in the Eye Infirmary the second time but I went to an optometrist who had the most elaborate apparatus I ever saw for examining the eyes. After an hour of much fussing on his part I was given glasses which did not at first suit my eyes. I tried them for two weeks or a little longer, I believe, and then I went back to him and complained that they did not suit my eyes.

"Oh," said he, "you must get accustomed to the glasses; your eyes will sooner or later be adjusted to them."

Receiving no further encouragement or help, I tried again for a short time, always afraid when I was crossing the street that I would have an accident, because before I reached the curb I thought I was there and would step up. At other times I reached the curb sooner than I thought I would and I stumbled a few times and almost fell.

I returned to the optometrist and demanded a different lens, which he gave me and this I wore until I came to Dr. Bates as a patient nineteen years ago. I was skeptical, too, just as some of our patients are when they first come to us for help. That is why I try to understand a new patient and to give him the encouragement and advice that he needs as soon as it is possible to do so.

What a blessing it was for me to meet Dr. Bates and to be relieved entirely of my eye trouble in six weeks' time. When Dr. Bates first examined my eyes, the letters of the test card up to the 30 line were clear and black. The next three lines I could not distinguish clearly, and every letter had a tail, which bothered me very much. He did not spend very much time with me because he said I was an easy case to cure and advised me what to do at home.

I did exactly as some of our patients do now. I did the wrong thing, but one thing I did not do was to put my glasses on again. I put them back in their case and placed them in the back of my bureau drawer where they remained until sometime later when I displayed them to my friends very much as I would an antique or a curiosity.

Some of my friends did not like to see me without glasses and told me so. I did not look so well without them, they said. Others said I would surely make my eyesight worse by not wearing them, while still others said that I may have been able to do without glasses at any time, and that perhaps I did not have to wear them. Of course, these remarks were not always encouraging, but just the same I believed in Dr. Bates and was determined to win out. After the fourth treatment I had more confidence in the Doctor and I made progress from then on, although there were days when I had sudden relapses and became somewhat discouraged. He often said this to me: **"If you are not afraid, you will obtain normal vision, but fear makes you strain; don't forget that."**

This mother was grateful for what I had told her of my experience and we began to treat her daughter with unusual success during her first visit. She went back to school and returned in a few weeks' time for more treatment and the first thing I noticed was that the wrinkles had vanished. Various test cards were given her so that she would not tire of the practice at school and at home. A few months after her first visit to us, she was pronounced cured. Her vision, which in the beginning was about half of the normal, and her sight for the near point had both improved to normal. It did not matter to her what size type she was asked to read or how close she held it. She could read it just as well at any distance. With the familiar test card and strange cards she became able to read 15/10 with each eye. She wrote us a letter of gratitude which encouraged us greatly.

What applies to the eyes also applies to the mind and other parts of the body. **Fear causes great suffering and often impairs the mind permanently. Relaxation and rest of the mind can only be obtained when we stop making an effort.** With more faith in those who are trying to help us, whether it is mentally, physically, spiritually, or otherwise, we help to remove all fear of what might happen to us. It is not the thing that has happened that causes one to be afraid, but it is the unknown that frightens us.

## Questions And Answers

Q – When palming and remembering black, is it advisable to keep the image stationary and to keep the same image, or is it just as good to shift from one object to another?

A – When palming and remembering black, one should imagine everything remembered to be moving and not stationary. It is necessary to shift from one image or from one object to another. Shift from part to part when looking at a object in the mind, memory, imagination; Notice tiny details – shift point to point on a small imaginary object – a Bee: shift on its yellow and black fur, eyes, nose, antennae, wings, feet, see it moving its legs, wings, face..., follow it as it takes off, fly's around through a field, lands on an apple in a tree, then fly's to, lands on a flower, see it moving up and down... as the wind lightly blows the flower, the bee fly's zig-zagging over a field of tall grass occasionally landing to investigate a flower, blade of grass, fly's along the river, over the sparkling water in the sunlight. Shift on each object the mind imagines as the minds eyes move from object to object, part to part.

Q – Would the reading of fine print at four inches be helpful?

A – The reading of fine print at four inches is usually helpful.

Q- While palming is it necessary to close the eyes?

A- Yes.

Q – Why is the reading of fine print a benefit?

A – Because it cannot be read by a strain or an effort. The eyes must be relaxed.

Q – My eyes feel fine after I palm and let my mind drift to various black objects. The period is more difficult, however.

A - Perfect mental pictures of ordinary objects means a perfect mental picture of a period. To try to see is an effort or strain and produces defective sight.

Q - Are floating specks serious? Sometimes they just flood my eyes like clouds of dust and greatly frighten me.

A - Floating specks are not serious. They are always imagined and never seen.

Shifting, central fixation, perfect memory, imagination, relaxation of mind, body and eyes removes floating specks, floaters.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MARCH, 1929

### The Period

Many people have difficulty in obtaining a mental picture of a small black period. They may try to see it by an effort which always fails. They may persist in their efforts to see or remember it, paying little or no attention to their failures or the cause of their failures. As long as they continue to strain by trying to see, they will always fail; the period becomes more indistinct.

A small black period is very readily seen. There is no letter, no figure, no object of any kind which can be obtained more easily. Demonstrate that an effort to see a small black period by staring, concentrating, trying to see, always makes it worse. **Rest, relaxation, the swing, shifting, are all a great help.** Practice with a large black letter. Imagine that the upper right corner has a small black period. Do the same with other parts of the large letter. This practice will enable you to understand **central fixation**, seeing best where you are looking. Central fixation can always be demonstrated when the sight is good. When the sight is poor or imperfect, central fixation is absent. Shift from black dot to black dot on various parts of the letter. Shift easy, continually, relaxed. Blink.

The benefits which can be obtained from the use of the period are very numerous.

**+A perfect memory can only be obtained when the sight is perfect.**

**+A perfect imagination can only be obtained when the sight and the memory are perfect.**

The period is the smallest letter or other object which is perfect or becomes perfect by perfect memory or perfect imagination.

Shift point to point (tiny part to tiny part) on a period to remember, imagine and see it clear. Blink, relax, see it 'swing', move in the opposite direction the eyes shift to.

Imagine a letter E is made of many small black dots (periods). Shift from dot to dot: left and right, top and bottom, middle, corner to corner and in any direction. Blink. Notice that shifting part to part (dot to dot) keeps the E clear.

See on a small dot at a time darkest black, clearest in the center of the visual field. 'Central Fixation'.

Combine shifting with central fixation. Imagine the dots smaller than in the example; imagine them as very small parts of the black ink of the letter E. 20, 50... tiny dots.

## Sympathetic Ophthalmia

By W. H. Bates, M.D.

I have been asked by the readers of this magazine what "sympathetic ophthalmia" really is. Many definitions of sympathetic ophthalmia have been given in my book and other publications. I will try, if I can, to explain it again in still simpler language. In sympathetic ophthalmia, the eyeball is soft when pressed lightly by the fingers of the attending physician. It is a serious symptom and unless it is corrected by treatment is followed by loss of sight. The reduced tension of the eyeball is usually due to an inflammation of the ciliary body - cyclitis - with loss of function.

**The function of the ciliary body is to supply fluids to the inside of the eyeball. When its function is modified, lessened, with less fluid excreted, the tension or hardness of the eyeball naturally becomes less. It is also a truth that when the ciliary body supplies more fluid to the inside of the eyeball than usual, the tension of the eyeball is increased with the symptoms of glaucoma.** In sympathetic ophthalmia, the activity of the glands of the ciliary body may be variable. For example, the increased tension of the eyeball may be due to an increased amount of fluid secreted by the ciliary body, while in other cases the amount of fluid secreted may be less than normal and the eyeball may be softer than it should be. The stimuli which regulate the activity of the ciliary body are variable. The mind controls the symptoms of strain.

When one eye is injured by a blow or by a foreign body lodged inside the globe, the other eye, from sympathy, becomes inflamed and diseased with loss of vision.

After the foreign body is removed one naturally expects benefit or complete recovery of both eyes. This rarely occurs. In a large percentage of cases the injured eye may heal and regain good vision, while the other eye may acquire a severe inflammation and become blind. When there is a doubt in the mind of the attending physician whether to remove the foreign body or not, the opinion of the patient may be valuable. If an eye containing a foreign body is removed, it is less dangerous to the other eye, which may heal more quickly. It is well to keep in mind that it is dangerous to practice a waiting policy, because one or both eyes may be lost from neglect. If the patient travels long distances he is likely to have trouble with one or both eyes. Soldiers, sailors, engineers, conductors, forest rangers, or others occupied without supervision, may be attacked at times or in places where no help can be obtained promptly. These people, for their own safety, are justified in having the eye with its foreign body immediately removed. It is far better to have the use of one eye than to be blinded in both.

For more than forty years I have been an eye surgeon and have removed injured eyes which contained foreign bodies which were not removable by an operation. It is only within recent years that I have been unable to operate because of a serious tubercular inflammation of my right elbow. Therefore when such cases come to me, I immediately refer them to other eye surgeons for proper surgical treatment.

One patient with sympathetic inflammation had an interesting history. At the age of twelve years he was accidentally struck in the right eye by a small lead shot which was followed almost immediately by a severe inflammation of the iris and ciliary body. **The foreign body might have been readily removed had it been of a different metal, such as steel, which responds to the**

**attraction of a magnet and may be removed with its help quite readily.** (A construction worker in California also told me this; while working, if he gets a small piece of metal stuck in his eye, he moves a magnet in front of the eye and the magnet pulls the metal out of the eye. In some cases only a doctor can remove a foreign object, as in cases where a blood vessel is cut and removing the object incorrectly can increase bleeding, cause more injury...) This patient, with the lead shot still in the right eye, recovered from the inflammation at the end of a few weeks, but with poor sight. Six years later at the age of eighteen, the vision of the right eye had improved, while the vision of the uninjured left eye was also improved.

When he was thirty-five years old he was brought to my office. For some unknown reason the uninjured eye, the left, had been removed. The patient was reluctant to explain why the good eye was removed, but some members of the family volunteered the statement that at the time of the operation the left eye was decidedly more inflamed than the right or injured eye. The vision of the injured eye was reduced to one tenth of the normal. Glasses did not improve his vision. The field was normal with the ophthalmoscope; the optic nerve and retina were seen, at first momentarily - later they were seen more continuously. I talked to the patient and learned many things. He told me that he was a day watchman in a gas company. His sight was too poor to do any work at night. When I told him that he was curable if he would only visit me at least once a year or once in two years, he showed signs of overwhelming gratitude.

#### Memory and Imagination

He promised to come once a week, or until he was temporarily cured. I improved his vision to the normal temporarily in a very short time. It was an unusual thing to do. The patient was not expecting it.

**The vision was improved by the following method:**

**He was told to imagine one letter, eye open, for a second, then close his eye and imagine the same letter for ten seconds and alternate, until one known letter is imagined correctly with the eye open. When this is done properly the one unknown letter becomes known and other letters of the same size are seen, not imagined. One can demonstrate that the imagination of a known letter improves the sight when the eyes are closed for ten seconds or longer. When this unknown letter is imagined sufficiently with the eyes closed it will be seen when the eyes are opened, and also other letters of the same size, at first for only one second with the eyes open and later more frequently or continuously.**

The patient was able to see a large letter of the Snellen card at two feet from his eye, but the letter was not seen perfectly; when he closed his eye and rested it with the aid of a memory of a more perfect letter his vision was temporarily improved for a second when he opened his eye. With the aid of rest, alternately closing his eye for ten seconds and then opening his eye, he imagined for two seconds an improvement in his sight. On the second line of the Snellen card he improved his vision with the aid of his memory and imagination.

He was told that the letters were a benefit to his memory and imagination and by alternately closing his eye and resting it, he became able to distinguish what the letters were when viewed at two feet. On the third line were three letters. He was told that the first letter was a letter T. When he closed his eye he was able to remember or imagine a better letter T. By practice, the letter improved and was distinguished farther off with the aid of his memory and imagination until he saw it quite clearly at ten feet. With practice he became able to see quite clearly other letters of the card, not with the aid of his memory or imagination but with the aid of his sight.

All the letters of the fourth line were blurred to such an extent that he could not recognize one of them. He was told that the last letter of the fourth line was a letter O and that it had a white center which was whiter than the rest of the card. Staring lowered his vision, while blinking was a benefit. He was asked to look directly at the unknown letter O and to imagine it was stationary. The patient did not feel satisfied and complained that it was impossible to imagine the unknown letter as being stationary. His vision became worse even for the known letters and he demonstrated that **the more he tried (used effort) to imagine or to see better, the worse his vision became. Conversely, when he did not try to imagine or to make his sight better or avoided all efforts to stop the swing, his vision improved.**

At one time as his eye was being examined while he was remembering, imagining a letter quite perfectly, the cloudiness of the interior part of the eye became less and his vision improved. If the patient had cataract, it could be demonstrated that, with the aid of the ophthalmoscope, with a good memory of one known letter, the cataract in the injured eye would become less and the vision would improve.

In many cases, patients with sympathetic ophthalmia are usually affected periodically - not continuously. Sometimes the affected eye will have relapses quite frequently. The prevention of relapses is often very difficult. A continuous memory of the optical swing can be demonstrated to be of great benefit.

One of the most difficult conditions to relieve is **cyclitis** in which the **affected eye has become soft**. In these cases the **ciliary body has atrophied**, which is followed by **loss of the fluids of the eye**. It is difficult, very difficult, in such cases, even with conditions most favorable, to bring about a sufficient amount of relaxation to promote a continuous flow of the normal fluids of the eye.

## Hypermetropia

By Emily A. Bates

Two cases of hypermetropia were being treated by me at the same time, and both had to be treated in a different way to obtain permanent benefit. The patients were man and wife and both were over fifty years of age. Such cases as these sometimes require many hours of study in order to relieve the symptoms of imperfect sight. These patients had trouble in reading at the near point and both suffered a great deal of pain which glasses did not relieve.

The man had worn glasses many years and for a time they helped him in his work. He had always been employed in some piano factory and did good work until he became ill with Bright's disease. After he returned to his work again, he found that his eyesight was impaired. His eyes were examined by an eye specialist of good standing and he was told that the Bright's disease had affected his eyesight. After some treatment by this doctor, who instilled some eye drops, his sight was improved. Some years later he had a relapse and he called on another doctor who prescribed glasses. These glasses did not do him any good. He was examined by another doctor who prescribed glasses that helped him for some time, when he noticed the **sclera or white parts of his eyes**

- 1-Eyes open-Shift on the C and remember, imagine and see it clear.
- 2-Eyes closed-Shift on the C in the mind and remember, imagine it clear.
- 3-Eyes open: Repeat 1, 2.

were bloodshot. He thought it was just a cold that had settled in his eyes but later the **redness in his eyes** increased and the **watery condition** alarmed him, so he came to me.

I tested his sight with the test cards and found the vision of each eye was impaired. His vision was 15/40 with each eye and he stared at every letter that he read. His wife who was with him drew his attention to this fact of which he was previously ignorant. The patient noticed that while he was reading, the watery condition increased. His sight was first tested with a white card with black letters and later with a black card with white letters. He read equally well with both cards, but the black card was more comfortable, so this one was given him to practice with at home.

We have small test cards which are similar to the large ones, for the benefit of patients who are very near-sighted or have diseases of the eyes which prevent them from reading the large card at the distance. I gave him one of these small black cards with white letters, (which was exactly the same as the larger card on the wall fifteen feet away) to hold in his hand. By reading the two cards alternately, his vision improved to 15/20; the redness of the white parts of his eyes was decidedly less, and the patient volunteered the statement that he had not felt so comfortable in a long time. I wanted to see if he could do as well with fine print and all he could read was sentence number 2 of the fundamental card. By closing his eyes frequently and remembering the white spaces between the lines of type, he became able to read number 5 in less than fifteen minutes' time. I gave him the sun treatment using my sun glass rapidly on his closed eyelids and advised his wife to do the same thing every day for him and to be sure that he did not open his eyes while the treatment was being given.

A month later the sclera or white parts of the eyes were no longer bloodshot and his vision for the black test card was 10/10. I boasted about his being able to read all of the fine print of the Fundamental card but he remarked: "Oh, that was nothing at all; I became able to read that fine print in less than a day." Sit in the sun, face the sun with eyes closed and move the head side to side. Relax. If you want to relax deeper and fall asleep and still obtain benefits of sunlight, sit under tree branches for partial shade, sunlight to avoid sunburn. When the wind blows through the branches, leaves - saccadic sunning occurs.

His wife, who also had **hypermetropia**, told me that at times with her glasses on she could see at a distance with no discomfort or pain, but at other times distant objects were very much blurred and seemed more distorted the more she tried to correct the trouble. For instance, a flag pole less than two hundred feet away would wriggle like a snake and there would appear to be two instead of one. She always used glasses while sewing and if the material had stripes or checks, the pattern appeared to come up toward her eyes, which frightened her and made her uncomfortable. She tried a new pair of glasses - bifocals - but she could not become accustomed to wearing them. She then decided to come to me for help.

When the examination was made, **cataract** was seen in her right eye and I told her about it, but quickly explained how it would disappear by the treatment I would give her. It was a shock to her, no doubt, to learn that she had a cataract but she wanted to know the truth and I could not conceal it. Her vision when tested was 6/200 with the right eye and 10/200 with the left and all the letters were blurred.

**Palming** helped her, and with her **good memory for colors and works of art, while palming**, the vision with her right eye which had cataract improved temporarily to 10/100 in less than an hour and her left eye to 10/40. The dear little woman did not worry about the cataract after that. When she found that her sight could be improved in such a short time she did not need much encouragement to practice. She did as I told her to do and in four months' time she had no sign of a cataract. **She could see distant objects clearly at all times if she practiced shifting from an object near by to the distance, remembering always to blink her eyes**, which she had failed to do before she began treatment.

#### Threading a Needle

If she had any trouble in threading a needle she would hold the needle where there was a background, close her eyes for part of a minute, **remembering a small letter "o" while her eyes were closed** and this would help her to thread the needle without delay or trouble.

The oculist who gave her the bifocals had been an old friend for years and he doubted very much that the Bates Method could give her a permanent relief because he knew she had incipient cataract of her right eye but feared to tell her about it. He believes now that the Bates Method cured her. I hope in the near future he will become a student of Dr. Bates and stop prescribing eye glasses, especially for those who do not like to wear them.

## Case Reports

Squint = Crossed/Wandering Eye Conditions Cured Naturally

(The following are reports of cases treated by Mrs. Edith Reid and Mr. Ian Jardine, Dr Bates' representatives in Johannesburg, South Africa.)

Squint is a very ugly disfigurement, especially when seen behind glasses. A girl of eighteen had been given glasses when she was three on account of a squint in the left eye. At eighteen the eye was straight, but she was almost totally blind in that eye, and suffered from severe headaches. After a few weeks' practice of the Bates Method, her headaches were relieved and the sight of the bad eye was about one half of normal.

**Most cases of squint are caused by strain and if the strain can be removed, the squint will disappear.**

A little boy of six, who had worn glasses for three years and was told that when he was eight he would have to be operated on to have the eye straightened, was able to **picture with his eyes closed a white cloud drifting across a blue sky**. When he opened his eyes, **still remembering this mental picture, his eyes were straight**. Having his eyes open and imagining that his dog was in the room with him, **immediately straightened the squint**. He has now reached the stage where he can make his eyes straight at will. He is reminded to do so, both at home and at school, as soon as the eye turns, with the result that after five months his eye is straight practically all day. His was a very bad

**Sunning**  
Face the sun, eyes closed, move the head side to side.

Boy closes his eyes and imagines a clear image of a white cloud drifting across a blue sky. Then, opens his eyes, still remembering, imagining the mental picture - his mind, eyes stay relaxed, eyes straight. Imagining his dog is with him also relaxes the mind, eyes, keeps the eyes straight, vision clear.

squint, the one eye being hardly visible, and with glasses the vision was 10/15. Today, he reads 20/10 easily without glasses and with eyes straight.

#### Movement of Childs Head Cures Squint

Another little fellow of four who was also threatened with an operation for squint and who had worn glasses for some time had his eyes straightened temporarily by having his head moved from side to side. His mother, who followed the whole proceedings, nearly had hysterics when I took her son's head between my hands and moved it from side to side. When I stopped, his eyes were straight for nearly five minutes, but he strained again and the right eye ran in almost under his nose. Again I moved his head and again the eyes were straight. The mother was most amused and excited to see his eye being apparently shaken straight just as one would with a doll's eye which had gotten out of place. After this had been repeated a few times I asked him more jokingly than seriously what he would do at home to straighten his eye when it went crooked. "I'll do this," he said, moving his head from side to side, and sure enough the eyes were straight again. This was kept up at home and now the little chap squints only occasionally when he is very tired or angry.

It is rather wonderful to think that so small a thing as moving the head from side to side could straighten a crooked eye when so many eye specialists were able to suggest only glasses or an operation.

A man thirty-eight years of age, whose eyes and health were in a very bad way, visited us on the 21<sup>st</sup> of October, 1927. He told us that he had been under chloroform 21 times and had had a series of injections for his eyes lasting 18 months. These at the instigation of three eye specialists in South Africa. As a result of the injections, he was compelled to go to bed every day at 12 o'clock, tired out, and every weekend was also spent in bed. He received no benefit. His eyes were so bad that even glasses could not be given him. **The right eye, slightly crossed, was blind with cataract and the left eye had been bad all his life. The doctors said that the optic nerve was diseased.** His test showed 10/70 and number 4 on the Fundamental card.

He was a printer by trade and had to have everything read to him. Also, he took on an average of two aspirin tablets every day to try to relieve his constant headaches.

He was taught to **palm, swing, and to sun his eyes**, all of which he has practiced regularly ever since. He was told to **blink all day long and to keep his eyes moving, never to stare or look hard at anything, and when he himself moved to notice the apparent movement of the stationary objects about him.** All this he has practiced most assiduously, with the result that on the 6<sup>th</sup> of February, 1928, he was able to read books for himself, sometimes even the newspaper, and was able to do all his own work without the aid of a "reader." With his blind eye he read the big "C" of the card one foot away.

Today he rides a bicycle about the city, plays tennis, and is able to thoroughly enjoy himself because of his better health and freedom from headaches.

He is a strong upholder of Dr. Bates' method and never tires of telling others of the wonderful results he has obtained in his own case. His wife and two children have also benefited by the help he was able to give them.

After reading the above, the patient asked if he might add something and if he might attach his signature to it. This is what he wrote:

"The left eye has been bad from the age of about seven years and I was under the best men in Melbourne, Australia, on and off till the age of 18 years, and they all told me nothing could be done for the left eye, the one I now read with. I have read the above and every word is true. I can never thank Mrs. Reid and Mr. Jardine for what they have done for me, and are still doing. I have hardly had a headache for the last twelve months and I no longer take aspirin. My average weight is now 150 pounds; before coming here it used to be 130-135 pounds.

"Yours with thanks for the Bates' Method.

"(Signed) Geo. H. Bowden."

#### Squint, Blindness, Nystagmus Cured and Eye Color (iris) Changed From Pink to Blue

One day in January a little boy was led to the office by his mother. He had **pink eyes**, white hair, a very white face, and even his lips were pale. **Both eyes had squint.** He was **almost blind** and had **severe nystagmus**. His mother was heartbroken and told of how she had worked her passage from South Africa to London so as to see what could be done for the little chap. Specialists had declared his case hopeless and had said that nothing could possibly be done.

She also took him to several hospitals, always hoping that he would be able to find some doctor who could offer a little hope, but every doctor who looked at the little fellow pronounced his case hopeless. She had to come back to South Africa as it was her home and her husband was there. She returned feeling thoroughly sad and miserable. She was told of Dr. Bates' method by a friend who had benefited greatly by it, so she came, hoping something could be done for her son. We immediately taught him how to **sun his eyes** and asked his mother to see that it was done **two or three times daily**. He was also shown how to rest his eyes by **palming**. He was a very bright, intelligent child which made it very easy to teach him; he understood and appeared to grasp all we said to him. Both mother and child left the office very happy and full of hope. He was not able to read, so he was given a book of pictures of animals.

At his next visit, which was three days later, he came in with the book under his arm and declared that he was feeling much better and that he was going to get quite well. After that, he was brought every day to get the **sun-glass treatment** and each day there was a marked improvement in the eyes. **They were turning from pink to blue; the blue came in patches which each day appeared to be spreading until the eyes became a beautiful blue.** He was being taught his alphabet so that he was able to practice with the **Snellen test card** which proved that his sight was improving wonderfully. The squint and the nystagmus had also improved very much.

The word squint has two meanings;

1 - squint = strabismus, crossed/wandering eyes.

2 - squint = Squinting - to partly close the eyelids, squeezing, keeping them close together in an attempt to see a object clearer. This gives a temporary state of clearer vision (due to the pinhole effect) while the eyes are squinting but leads to increased eye muscle tension, muscle tension in the face, head, neck, shoulders, disrupts shifting, central fixation resulting in increased vision impairment.

Avoid squinting; Replace it with shifting, blinking, central fixation, relaxation.

## Questions And Answers

Q - While palming, is it necessary to close the eyes?

A - Yes.

Q - When I read and blink consciously, I lose my place.

A - This is caused by strain, which prevents one from remembering the location of the letters.

Q - How long is it necessary to read the test card before obtaining benefit?

A - Some patients by palming and resting their eyes have obtained benefit in a few minutes.

Q - How can I prevent the sun from hurting my eyes?

A - By becoming accustomed to sun treatment.

Q - Will you please tell me if results are obtained at all ages?

A - Results can be obtained at all ages.

Q - What is the circular swing and how is it practiced?

A - The circular swing is described in the June, 1928, number of "Better Eyesight." Modern Infinity Swing, Figure Eight is Best.

Q - I get nervous if I palm for any longer than ten minutes at a time. Can I obtain as much benefit by palming for short periods at more frequent intervals?

A - Yes.

Q - Is there a possibility of palming wrong? I can obtain some benefit, but later I feel strained.

A - Palming may be done properly or it may be done wrong. I would suggest that you read the chapter on palming in my book.

Q - Explain what you mean when you say "imperfect sight, imperfect memory."

A - If you see an object, (letter) imperfectly, blurred or gray instead of black, you cannot remember it perfectly. You will remember it as you see it.

Q - My left eye turned in and was corrected by operation. Now it turns out. What method will cure this?

A - You need more than one method. Complete relaxation will relieve the strain and correct the squint.

Left and right brain hemisphere activation, integration, neck muscle relaxation, movement.

Q - Is a great amount of floating specks indicative of cataract? When I am weary these look like a flock of bees crossing my eyeballs.

A - No. Your particular strain produces floating specks. A different strain produces cataract.

Q - Would the reading of fine print at four inches be helpful?

A - The reading of fine print at four inches is usually helpful.

Q - Why is fine print beneficial?

A - Fine print is beneficial because it cannot be read by a strain or effort. The eyes must be relaxed.

Fine print activates, improves perfect central fixation, relaxation, tiny shifting. This improves ability to see small, fine details of objects clear at close and far distances.

Q - How can one overcome the stare if it is unconscious?

A - Blink consciously, whenever possible, especially when reading. Never look at an object for more than a few seconds at a time.

Shift your gaze: object to object, distance to distance, part to part on objects, small point to small point on parts of objects and on tiny objects.

Q - If type can be seen more distinctly with the eyes partly closed, (squinting) is it advisable to read that way?

A - No, it is not advisable to read that way because it is a strain, causes eye muscle tension, and alters the shape of the eyeball causing incorrect focus of light rays in the eye.

Q - I have attained normal vision, but after reading for a while, my eyes feel strained. Would you still consider I had normal sight?

A - If your eyes feel strained you are not reading with normal vision - Not reading with relaxation, interest in the subject, shifting, blinking.

Q - Are dark sun glasses harmful?

A - Yes. Dark glasses are very injurious to the eyes.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

APRIL, 1929

### Blinking

**Blinking** is one of the best methods that may be employed to obtain relaxation or rest. When rest is obtained by blinking, the vision is improved, not only for one letter or part of one letter, but for all the letters of a page, which may be seen some parts best, other parts not so well. This is called **central fixation** and one cannot see anything clearly without it. In order to maintain central fixation there should be continuous opening and closing of the eyes by blinking which makes it easier for the vision to improve. When the eye discontinues to blink, it usually stares, strains, and tries to see. Blinking is beneficial only when practiced in the right way.

What is the right way? The question may be answered almost as briefly as it is asked. Blinking when done properly is slow, short, and easy. One may open and close the eyes an innumerable number of times in one second, and do so unconsciously.

Lord Macaulay was able to read a page of print in one second, and blinked for every letter. In order to read perfectly, he had to see each side of every letter by central fixation. We know that he acquired or had a perfect memory, because it was only with a perfect memory that he could recite the pages of any book which he had read many years before.

A casual observer would not be able to determine the number of times Lord Macaulay blinked, as it was done so quickly and easily, without any effort on his part. While most of us will not be able to blink without effort as frequently as Lord Macaulay did, it is well to practice his methods as well as we can. Those with imperfect sight who do not blink sufficiently should watch someone with normal eyes blink unconsciously and then imitate him.

### Illusions

By W. H. Bates, M.D.

Many people who know little or nothing about physiological optics have the habit of criticizing adversely anyone who has the courage, or who is foolish enough, to announce discoveries which do not meet with the favor of people who theorize. In order to bring about quick and lasting cures of myopia, hypermetropia, astigmatism, and many other causes of imperfect sight, one needs to know a great deal about illusions.

Many years ago a student of the eye, a man of great authority, after studying the illusions of perfect sight and comparing these illusions with those of imperfect sight, was very much upset because the more facts he obtained, the greater became the illusions. He finally made the statement that "seeing is deceiving." By this he meant that no one could understand the physiology of the eye without going to a great deal of trouble to prove that somebody else was deceiving the scientific world. He admitted that he was very much discouraged himself by the large number of illusions which were imagined or seen. To correct most diseases of the eyes it is absolutely necessary that one should learn by repeated experimental work something about illusions.

Unfortunately for the rest of us, this man was persecuted by his friends to such an extent that it ceased to be a joke and became a matter of great importance. It was hard for him even with all his "backbone," which was considerable, to keep on studying illusions when these studies were so very unpopular.

It may be a shock to some people who have not studied the illusions of vision to find that imperfect sight is difficult. In fact it is so difficult that the majority of people in this world dodge the illusions of imperfect sight because these illusions are usually so disagreeable or painful. Perfect sight can only be obtained easily without staring or straining to see. When the eye is normal, any effort to improve it always makes it worse.

It has been proven over and over again that with perfect sight the eyes are completely at rest. The movement that they always have is necessary in order to prevent the stare and other efforts to see which are difficult, painful, disagreeable, and cause fatigue. But when the eye with normal sight is permitted to move sufficiently to prevent the stare or the strain, the head and eyes do not make any effort. To make an effort requires that the eye should be kept stationary. When the eye stares it is always stationary; when the eye stares, it is always trying to be immovable unconsciously. The stare is only possible when a mental effort is made, consciously or unconsciously, to imagine that everything is stationary.

The normal movements of the eyes are passive. As soon as they become active and the eye is made to move by a strain, or stare, then the movement of the eye is no longer passive, it is active and it is this active movement of the eyes done consciously or even unconsciously which causes so much trouble. This is why shifting is practiced in a relaxed, easy, effortless way, with the goal of it becoming a automatic normal eye function, habit, occurring on its own, a subconscious function, just as the heart and lungs beat, breathe automatically. Practice the Bates method, shifting, central fixation... then 'take a break', 'don't practice', forget about the eyes and let the eyes shift... on their own. Return to practice if blur, strain, squinting, staring occurs in order to remove these incorrect functions and reinforce correct function.

This question is often asked: "What is the evidence that the normal eye is permitted to stare and strain unconsciously?" This is the answer. Many people can stare or strain as much during sleep as when they are awake. **If the active strain is practiced, a patient may awake in the morning with pain in the eyes, head or in other parts of the body or they may feel a sense of great fatigue. The vision is always worse.** When the passive movement of the eyes occurs, the movement may be imagined passively. The active movement requires the stare, strain, or an effort to remember, imagine, or see. This can often be recognized in myopia. The retinoscope is a great help in discovering the active swinging of the eyes. When the patient is asleep and straining the eyes unconsciously, the stare or strain is recognized with the aid of the retinoscope.

**NEGATIVE AFTER-IMAGES:** When a person with good sight regards a white Snellen test card which has black letters and does so with his eyes open, he may see the truth, that the white card appears white and the black letters appear black. When the eyes are closed an illusion is sometimes evident: the white card when remembered appears black and the black letters appear white. This illusion is promptly corrected with the aid of central fixation. One patient, a teacher of mental science, was able to see a white pillow perfectly white with his eyes open, but when he closed his eyes an illusion was seen or imagined at once - the white pillow appeared to turn into a black one. This was a great surprise to the professor. The illusion was prevented when the eyes were closed, by remembering or imagining each part in turn of the pillow best. He was then recommended to see two corners at the same time.

The illusion returned, but it required a strain in order to bring it back.

The patient's memory was improved by practicing central fixation with the eyes closed, seeing, imagining, or remembering one corner of a pillow at a time best and the rest of it worse. It was all done so quickly that the patient was not able quickly to remember, imagine, or see by central fixation. When he became able to produce the illusion or to prevent the illusion, his memory, imagination, and sight were very much improved.

He had worn glasses for the relief of headache for more than fifty years. It was a new and pleasant sensation for him to discard his glasses without suffering, as he had previously, with frightful headaches. The correction of various illusions of the sight are one of the best methods we have for the cure of imperfect sight without the use of glasses. If we correct the illusion, the eyesight may be improved.

One time I happened to be in the office of a well known professor of astronomy. With me was a high school girl, one of my patients, who wanted to learn something about astronomy. The professor asked us what we would like to see and with the naked eye I looked up toward the center of the sky where one could see the moon about the size of a nickel. I spoke to the professor and told him that I had so often seen the moon appear as big as a house and instead of being a dull gray it was usually a fiery red. I told him that I would be very much obliged if he would explain to me why the moon looked so much larger on the horizon than it did overhead. The professor said that there was a change in the density of the atmosphere when the moon was viewed low down on the horizon, which was entirely different from the air overhead. This, of course, is an illusion, not of imperfect sight, but of perfect sight, caused by conditions over which we have no control.

A man interested in the illusions of imperfect sight reported the following facts. One morning when he entered the bathroom he was surprised to observe that the tiles composing the floor had changed their colors. All the blue tiles had become pink and all the pink tiles had changed to blue. The illusion was very vivid. "What can I do?" he asked, "to prevent this illusion, because it is maintained with a strain or effort to see which lowers my vision?" He was advised to practice central fixation which prevented or relieved the illusion very promptly.

Illusions are not harmless, as many people may think. They are always one cause of pain with imperfect sight. It is interesting to observe that when an illusion causes imperfect sight it also causes the stare, strain to see, or an imperfect memory (imagination) with poor vision.

**Illusions which are beneficial do not cause pain, dizziness, fatigue, or any discomfort whatever. Beneficial illusions always improve the sight. For example: The thin, white line below the bottom of a line of letters** is an illusion because there is no white line there. When it can be imagined, the vision is improved and this illusion is so important, even necessary, that one cannot read small letters or the newspaper unless the thin white line is imagined. The thin white line helps to improve the imagination of the black letters so that they can be read in a dim light. Other beneficial illusions are: white halos, glow around and inside letters, white glow on a blue sky above trees, mountains..., the illusion of oppositional movement 'the swing'.

The same man described the illusions he had when a headache bothered him in the morning soon after opening his eyes. In one illusion there seemed to be a thin white transparent curtain floating up to the ceiling and then slowly dropping downwards toward the bed. It surprised him very much to observe that when the illusion of the floating curtain was manifestly at its height that the headaches became worse and a severe pain was felt in his eyes, head, and in other parts of the body. The illusion lasted about fifteen minutes and slowly disappeared. In this case also, central fixation was a great help in correcting or preventing the illusion.

A well known surgeon of the city of New York came to me for **treatment of illusions**. He had so many of them that the available space of this magazine is too small to describe them all. Among his many illusions was the fact that at irregular intervals while walking along the street, he would suddenly become **totally blind** and unable to see the light of the sun even when he looked straight at it. The blindness would continue for about a minute, usually less. The frequency of these attacks increased.

In the beginning he had three or four in a week, but after some months he had a **partial or complete attack of blindness** more frequently. The attacks made him very dependent; he was afraid that he might have one in the midst of a surgical operation.

Double Vision - How to Produce and Cure It.

While he was being treated, an illusion of double vision became almost constant and interfered very much with his vision for the Snellen test card. The illusions of double vision were corrected by teaching him how consciously to produce them rapidly and in any form. That is to say, he could imagine two lights, one directly above the other, at an angle of 90 degrees or when he strained sufficiently the two lights would be seen on a horizontal plane. With the help of the stare, strain, or trying to see better, he saw the two images at an angle of 45 degrees, 60 degrees, or 75 degrees. In short, he became able, after some instruction, to produce double images close together or double images farther apart and at any angle he desired. During the many months of treatment he demonstrated without knowing himself that he was able to produce illusions at will. Furthermore, he was able to produce illusions which lowered his vision and illusions which improved his sight. To produce double images, one above the other, he looked at a light about ten feet away and strained to see a small letter just below it at an angle of 90 degrees. To obtain double vision at an angle of 90 degrees required an effort.

I called this doctor's attention to the fact that in order to produce an illusion of letters of the Snellen test card or to produce double vision required a stare or strain. I asked him this question: "Would you like to learn how to produce double vision of the Snellen test card?" He answered, "I do not see how you can do it, but the matter is so interesting I am willing that you should produce or show me how to produce double vision." He was taught how to produce double vision consciously and this pleased him very much. Finally the day came when he was getting so restless that I thought I was justified in helping him to get rid of the double vision by teaching him how to produce the blindness consciously. He objected very much at first but more of the nerve specialists tried to convince him that he was incurable and that if he had let the matter go untreated he would have attacks of double vision almost continuously and be compelled to give up his work. **The patient was told how to produce all kinds of illusions and that in order to produce illusions of double vision he would have to go to considerable trouble to accomplish it.** He was finally persuaded or convinced that if my methods failed there was no help for him and so we began.

Creates and Cures Blindness

**I had a very hard time in making this patient blind consciously.** The strain was terrible and he did not take it calmly, but he finally made himself **totally blind** so that he could look straight at the sun without being able to see light. **The blindness continued for about five minutes when it suddenly disappeared and the sight was just as good as it ever was.** He finally came to me less frequently than every day. **Eventually he became able consciously to increase the length of time of the blindness, and while still blind he could, with the help of central fixation and other methods, obtain his previous normal vision.** Some of my other patients out of curiosity made themselves totally blind by the same methods practiced by him. When war was declared between Germany and France he enlisted in the medical department of the French Army; he never had a single relapse; he knew the cause of his double vision and how it was produced and was therefore able to avoid it.

## Mental Strain

By Emily A. Bates

Children who are nearsighted are suffering from a mental strain. Children who are cross-eyed are also suffering from mental strain. Eyes that have been injured, as by a foreign body entering the inside of the eyeball, even after it has been removed, may be responsible for a mental strain. This strain is different from that caused by nearsightedness or cross eyes.

Mental strain is only evident in these cases when symptoms are present. Children who are nearsighted are not always conscious of it. Therefore, at such times mental strain and the myopic condition are less, and the retinoscope has proved this in every case examined by Dr. Bates. What is true of children is also true of adults. After an attack of whooping cough or fever, such as measles, scarlet fever, diphtheria, malaria, hay fever, or other conditions, some patients have acquired **cross eyes**. Sometimes the right eye turns in while the left eye is straight, or the reverse may be observed. The eye which turns in usually has imperfect sight, while the eye which is straight may have normal vision for distant objects and for near objects. These cases can always be benefited. Strain, which is evident in cases of cross eyes may be relieved, but never cured, by wearing eyeglasses. All such cases under my observation have proved this to be true. Some patients have told me that they feel a sense of relief when they remove their glasses. It is the mental strain that is relieved and not the eyestrain.

When a child is placed under my care for the cure of squint or cross eyes, before I test the sight I hold a short conversation with the child to find out his mental attitude. It helps me to treat the child successfully and it helps my young patient to become acquainted with me. It is always best to have the guardian or parent in the room during the treatment given the child so that they can help in the home treatment, but sometimes I wish that I could be alone with my patient. I can do better work. This desire only comes when an anxious mother continually nags her child to do as I wish. Repeating to my patient that he or she must be good, must sit still, or must do as I say, is only a waste of time and does not help.

Some children troubled with cross eyes have very sensitive minds and constant or frequent nagging or scolding only causes more mental strain. While I was assisting Dr. Bates at the Harlem Hospital Clinic I was able to study the child mind. I found in cases of squint or cross eyes, which is the same thing, that children who were fortunate enough to have parents who loved them and helped them were cured of this trouble much quicker than those who were less fortunate. Sometimes I would send for the school teacher when a case was hard for me to benefit and with her help at school, encouraging the child to **practice with the test card**, with the aid of **palming** and the **long swing**, **in due time the eyes would become perfectly straight and the vision normal**.

In the early days of our work together, we gave test cards away to our clinic patients so that they would surely practice at home or at school or elsewhere. For the child of the clinic there was no alternative. They could not afford glasses; they must be cured without. A short while ago a little woman came to our office and with her was a girl twelve years old who was just a head taller than the woman. She asked to see me and when she stood before me she smilingly asked if I didn't remember her. This question is asked of me quite often by patients I have not seen for a few years and I do not always remember. When she smiled and spoke in her usual slow way, I recognized her. I said, "Of course, I remember you and this big girl is Ruth whom I treated for cross eyes at the hospital clinic nine years ago."

She apologized for taking up my time but said that Ruth was anxious to see me again because she had forgotten how I looked and she did want me to see how straight her eyes were. Indeed I was glad to see my little patient all grown up and I like to boast of my work being so well done. The mother also deserves credit for the cure of Ruth's eyes. Every day before the school hour the child practiced reading the test card letters with her mother to help her if she made a mistake. Immediately after school she practiced again. When her test cards became soiled she sent for new ones. Her efforts and mine were all worthwhile because Ruth can read all letters of any test card with either eye.

**There is always a mental strain while glasses are worn.** Sometimes patients are not conscious of it until they are informed that their glasses must be changed for a stronger pair. During the absence of Dr. Bates, I have been called upon to take care of his practice. At such a time I remember a patient placing on my desk four pairs of glasses which she wore at different times of the day. One pair was worn while she was reading or sewing, another pair for the movies or theatre, another pair, amber colored, to wear in the bright sunlight and the strongest pair she was advised to wear early in the morning at which time she suffered most pain and discomfort. She did not realize that she strained during sleep, which explained the pain and discomfort she had in the morning. I did not help her until after I had corrected the mental strain. After that it did not take me long to give her normal vision. The patient helped me by following my directions, practicing at home and elsewhere those things which helped her the most.

For many years she had avoided the bright sunlight, so during her first treatment I placed her near a window where the sun was shining. While her eyes were closed and shaded with the palm of her hand, I led her to the window. **I used my sun glass, focusing it quickly on her closed eyelids, first on one eye and then on the other.** Sometimes this treatment when it is first given causes a tearing of the eyes which is only temporary, but this patient had no such trouble. She enjoyed it so much that she asked for more of it. When there was no sun, a strong electric light was used with benefit. After the patient had had a few treatments, her vision improved for the near point and for the distance. After she had been doing well for some days she suddenly had a relapse and her vision was lowered. I asked her if she had put on her glasses again and she admitted that she had done so. In her case this was the worst thing she could do. It retarded her cure and made my task more difficult. I felt keenly her mental strain and proved without a doubt that imperfect sight is contagious, for I suffered with her mentally. Long ago, Dr. Bates trained my mind so that I would not lose patience with those who were under treatment for their eyes, but just the same neither he nor I are immune to their suffering or mental strain. We give each other the same treatment we give our patients sometimes when the day is almost done, so that we can enjoy the remainder of the day without any strain or discomfort. **It requires only a few minutes to relieve the mind of strain when you know how to do it.**

## Questions And Answers

Q - Which is the best method of obtaining relaxation?

A - The object of all the methods I recommend is relaxation. Some patients obtain more benefit from the practice of one method than another.

Q - When palming and remembering black, is it advisable to keep the image stationary and to keep the same image, or is it just as good to shift from one object to another?

A - When palming and remembering black, one should imagine everything remembered to be moving and not stationary. It is necessary to shift from one image or from one object to another.

Q - How long is it necessary to read the test card before obtaining benefit?

A - Some patients by palming and resting their eyes have obtained benefits in a few minutes.

Q - What is most helpful when one is dreadfully nearsighted and finds it almost impossible to see without glasses?

A - Practice palming as frequently as possible every day. Keeping the eyes closed whenever convenient for five minutes ten times a day is also helpful.

Q - I have noticed when I palm that my eyeballs hurt from the pressure. When I loosen this tension the light filters in.

A - Palming is done correctly with the fingers closed and laid gently over each eye, using the palms like a cup. If this is done properly there is no pressure and the light is shut out.

Q - Is there a possibility of palming wrong? I can obtain some benefit, but later I feel strained.

A - Palming may be done properly or it may be done wrong. Read the chapter on palming in my book.

Q - Should children read microscopic type?

A - Yes. Reading microscopic type is a benefit to the eyes of both children and adults.

**Q - Dr. Bates says that in reading fine print one should look between the lines. Is this not contrary to the principles of central fixation? To see the print best, should one not look directly at it?**

**A - One can look between the lines and shift to the black letters with central fixation.** Look directly at the letters when reading them.

Q - When I look at an object and blink, it appears to jump with each blink. Would this be considered the short swing?

A - Yes. You unconsciously look from one side to the other of the object when blinking.

Q - After palming for ten minutes or longer, my eyes are rested, but I feel sleepy.

A - The palming is not perfect. Try imagining stationary objects to be moving when you palm. Shift on the objects in the imagination.

Q - My eyes feel fine after I palm and let my mind drift on various black objects. However, the period is more difficult.

A - Perfect mental pictures of ordinary objects means a perfect mental picture of a period. To try to see is an effort or strain, and produces defective vision. Shift on the period in the imagination.

Q - Should I think only of a black period when palming? Should I imagine my body swaying and the period moving?

A - If it requires an effort for you to think of a period, you should not try to do so. It is just as beneficial to let your mind drift from one pleasant thought to another. When one remembers a period, it should be imagined to be moving from side to side. (as the eyes, mental visual attention is shifting on it.)

Q - Should one always imagine stationary objects to be moving in the opposite direction?

A - When one is riding in a train, one should imagine that telegraph poles and other stationary objects are moving in the opposite direction. When one is walking on the street, he can imagine when looking down, that the pavement is coming toward him; when he looks to the right or left, he can imagine that objects on either side are moving opposite. The object of this is to avoid the stare.

Q - Will you please describe the long swing?

A - The long swing is accomplished as follows: Stand with the feet about one foot apart, turn the body to the right - at the same time lifting the heel of the left foot. The head and eyes move with the body. Now place the left heel on the floor, turn the body to the left, raising the heel of the right foot. Alternate.

Q - How do you practice the variable swing?

A - Hold the forefinger of one hand six inches from the right eye and about the same distance to the right, look straight ahead and move the head a short distance from side to side. The finger appears to move.

Palm and imagine something pleasant, happy. Relax, let the mind drift. See objects in the mind clear without effort.

Q - What is central fixation?

A - Central fixation is seeing best where you are looking, and worse where you are not looking. That is, when you look at a chair, for instance, do not try to see the whole object at once, look first at the back of it, seeing that part best and other parts worse. Remember to blink as you quickly shift your glance from the back to the seat and legs, seeing each part best in turn.

Q - How much time should I devote to palming each day?

A - The more time one devotes to palming, the quicker will results be obtained, provided one practices correctly. Palming should be practiced for five, ten, fifteen minutes or longer at a time. Some patients obtain more benefits from practicing palming for short periods of time at more frequent intervals.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MAY, 1929

### Shifting

When the normal eye has normal sight it is at rest and when it is at rest it is always moving or shifting. Shifting may be done consciously with improvement in the vision, or it may be done unconsciously with impaired vision.

Shifting can be practiced correctly and incorrectly.

**+A wrong way to shift is to turn the head to the right while the eyes are turned to the left, or to turn the head to the left while the eyes are turned to the right.**

**+Correct way = Eyes, head/face, body move together, synchronized, same time, same direction.**

To improve imperfect sight by shifting, it is well to move the head and eyes so far away that the first letter or object imagined is too far away to be seen at all clearly. Shifting from small letters to large letters alternately may be a greater benefit than shifting from one small letter to another small letter. Quite frequently the vision is decidedly improved by shifting continuously from one side of a small letter to the other side, while the letter is imagined to be moving in the opposite direction. **When the shifting is slow, short, and easy, the best results in the improvement in the vision are obtained.**

The eye also moves quick, very fast (Saccadic) and this occurs automatically. Any attempt to stop the shifting always lowers the vision. The letter or other object which appeared to move is usually shifting a short distance - one half or one quarter of an inch. It is not possible to imagine any particular letter or other object stationary for a longer time than one minute. Strain, blur begins when the eyes have not moved after a fraction of a second to one second.

While the patient is seated, benefit can be obtained from shifting, but even more benefit can be obtained when the shifting is practiced while the patient is standing and moving the head and shoulders, in fact the whole body, a very short distance from side to side. (The Sway, Rock) Shifting the whole body makes it easier to shift a short distance and may explain why this method is best. It is easy to see letters on a eyechart clear when shifting easily on the letters while doing the sway a short distance left and right. Blink, sway, relax.

## Treatment

By W. H. Bates, M.D.

**Vision is largely associated with the activity of the mind. The memory, imagination, must be nearly perfect for the vision to be nearly perfect.** When the memory is imperfect, the imagination and sight are always imperfect. There are no exceptions.

In **MYOPIA**, or short sight, (unclear distant vision) the eyeball is elongated. Myopia can be produced by a stare, concentration, or an effort to see distant objects. When all objects are regarded with an effort to see more than two parts perfectly at the same time, myopia is always produced. (Shift from part to part, seeing one part at a time perfect, clearest produces clear vision) To do the wrong thing, a strain or effort is made. The greater the strain, the more imperfect becomes the vision. To do the wrong thing requires much trouble, hard work, and a useless effort. The production of myopia is not easy. Rather it is difficult. This truth, when demonstrated by the patient, is important. It demonstrates the cause of myopia and when the cause of myopia is known, treatment can usually be suggested which helps in the cure.

The production of improved or perfect sight is easy. Rest or the absence of strain is helpful in obtaining normal vision.

When the sight is normal, the eye is at rest. **Any effort to improve the sight is wrong, always fails, and the vision soon becomes less.** Perfect sight is easy and is not benefited by strong efforts to improve the sight. **Myopia is cured by the efforts which are not made, rather than by strong efforts to see.** Most people with myopia are not conscious of the stare, strain, or effort. Persons with normal sight are often able successfully to demonstrate the existence of strain in myopia and to suggest successful methods of treatment for the prevention of strain.

**One method of treatment has been practiced consciously, continuously, and successfully, namely: "Make the sight worse by a strong effort to stare."** The imperfect sight of myopia does not come easily by staring. When it does come the patient feels a manifest strain in his head and all his nerves. By alternately producing the stare consciously and unconsciously he realizes the harm it can produce. He becomes acquainted with the stare. By practice, he becomes able to produce it to any extent and at all times.

Imperfect sight is difficult and normal or improved sight is easy and enables most people with myopia to obtain a cure in a very short time. It should be known that high degrees of myopia are not always easy to produce. It is a truth that quick cures of myopia can only be obtained by persons who have the ability to make the myopia worse.

Some statistics on the production of myopia in school children and others show that 10 percent of the population are myopic, 80 percent have imperfect sight from other causes, and 10 percent have normal sight. Some statistics state that 50 percent of the

population of China and about the same percentage in Japan have acquired myopia by improper use of their eyes. What is improper use of the eyes, and what is known of the cause of myopia in these countries? They are a book-reading people to such a slight extent that we need not consider the use of books in the daily life of the Chinese. No one can say that the Chinese have acquired imperfect sight from reading. The characters of the books that they do possess are very large compared to our print and that used in other countries. Many writers have stated that fine print is a strain on the eyesight, and is the cause of myopia; the Chinese use very large print and there is no nation in the world that has so much myopia! Large print instead of being a rest to the eyes is a great strain.

Some years ago, a prominent ophthalmologist of Cleveland was told to introduce in the public schools books printed in very large type. After a short time, the teachers complained to the authorities that the large print hurt the eyes of the children and increased the production of myopia and made so much trouble that they requested that the new books be discarded and books with finer print be used again. This is offered as evidence that myopia does not result from the reading of fine print. Fine print, instead of being the cause of nearsightedness, is the best preventative that one can use. One should not stare at the letters of fine print, but rather, he should take a break and look at the white spaces between the lines, look to other objects, then, when the eyes are relaxed, look back to the fine print. Blink, relax, shift on/along the words or through the center of the words as the sentences are read. Look at the white spaces or distant objects to rest the eyes, then back to the print. In this way the print is seen without strain.

The Snellen test card can be used in various ways to improve the vision. The best distance of the card from the patient is variable. Some patients with a high degree of myopia will improve more when the card is read at a short distance, five feet or less. Other patients prefer to have the test card at a greater distance from their eyes and they improve their vision more when they practice with the card at a long distance off - twenty-five, thirty, or, forty feet. The optimum distance of the card from the patient is the distance at which the best results are obtained. To imagine the card to be moving, when held in front of the patient, who at the same time sways from side to side, is usually beneficial. After a little practice, when the patient sways from side to side, the card may be imagined to be moving about four to six inches from side to side. If the card seems to sway a very short distance or not at all, it usually means that the patient is staring, straining, or trying to see.

One should avoid looking directly at the Snellen test card, because then the movement of the card becomes uncertain or disappears altogether. **A long movement of the card from side to side can be shortened with an improvement in the vision. When the patient stands with the feet about one foot apart and sways from side to side, without looking directly at the card, the letters may be seen to move in the same or in the opposite direction.**

The correct result is for the letters to move opposite - 'oppositional movement'. If a object is in front of the card, closer to you, the card, letters appear to move with, in the same direction as the eyes, head, body. The shorter the sway, the shorter the oppositional movement.

Sometimes practice with the card will be followed by double or multiple vision, due to the fact that the patient stares, strains, and makes an effort to see the letters. For example, one patient saw one line of letters multiplied two or three times. This would not have occurred if the patient had imagined the card moving slightly from side to side, and had not tried to see the letters. Palming, when practiced successfully, has relieved many cases of double vision. Some letters, objects appear double, triple as the blur and any underlying astigmatism is removed and the brain, eye muscles relax, left and right brain hemispheres work together, correct with eyes, eye muscles.

Some patients, when they palm, see flashes of light and all the colors of the spectrum, without at any time seeing black. It is strange to hear patients complain of the numerous objects they remember or imagine when they palm. Thinking of pleasant things has helped some people to palm more successfully. The memory of imperfect sight is a strain and should not be practiced when palming. The length of time that patients can palm with benefit is widely variable. Some patients have gone to sleep while palming and when they awakened in the morning they were still palming, with their hand covering their eyes, with the result that their vision was very much improved. Others obtain more benefit from palming for short periods of time at frequent intervals.

#### The Thin White Line

If one can imagine a **thin white line below letters of the test card or beneath a line of fine print it is very helpful.** This thin white line is only imagined, it is not seen, because the line is not really there. It is valuable in the treatment and cure of presbyopia, hypermetropia, astigmatism and many cases of myopia. It is well to imagine it in the right way. The wrong way is to try to imagine the thin white line and the black letters at the same time. This is a strain which always blurs the black letters and prevents the thin white line from being imagined. It is actually seen, it appears and is a beneficial illusion.

Many patients complain that they have difficulty in imagining the thin white line. To overcome this, one should imagine it just below some word or collection of words which are known. The line is then readily imagined and it can be imagined extending from one side of the page to the other, and wherever it becomes manifest the vision is always improved. One can read rapidly, clearly, and without discomfort, when he is conscious of the thin white line, but to fix the black letters and expect to read them is a mistake which very few teachers or students have observed. The fact that one cannot read properly when looking at the black letters should be more widely known. Much time has been lost in the class room by teachers trying to force the children to look directly at the blackness of the black letters. When black letters are regarded and seen best, much pain, discomfort, or imperfect sight is experienced: If staring, squinting, effort, diffusion to see the letters clear is used.

One cannot be sure when imagining the thin white line that the eyes are directed toward it. When one plans to look at the thin white line and while trying to read something feels discomfort or pain, it means that the eyes are not directed on the thin white line as the reader may imagine.

Bates writing about the white spaces, thin white line is a bit confusing. Modern teachers state; to see a letter, object clear; look directly at it. I believe Bates means for the person to be able to see the thin white line by looking directly at it, shifting back and forth from the letters to the white line, to the letters again... To shift to the black letters, look directly at them, move the eyes on the letters to read, see them clear. No staring at the white line/spaces, no staring at the letters. Let the eyes shift, move, blink, relax.

Modern teachers have removed many of Bates paragraphs concerning the white spaces and thin white line.

They are left in this book so the reader can obtain Dr. Bates original work. In other issues of Better Eyesight Magazine Dr. Bates gives these modern directions. The blue print is by Clark Night to explain Modern versions of the methods.

- + Sway left and right in front of the eyechart and see it move, 'swing by' in the opposite direction the body, head, eyes move toward.
- + Then sway shorter side to side, 4-6 inches and see a shorter opposite movement.
- + Shorten the sway to 1-2 inches and see a very small opposite movement.
- + Shift left and right on a small letter and see an even smaller opposite movement.
- + Shift on a tiny period and see a tiny opposite movement = Very clear vision!

Just remember; when you want to see the thin white line or white spaces; look directly at them. 'Central Fixation.' Shift on them.

If you want to see/read the black letters; look directly at the black letters. 'Central fixation.' Shift, move the eyes along the sentence.

The white spaces and line will also appear in the peripheral field when reading the black print in the center of the visual field and when shifting from sentence to sentence, spaces to words, words to spaces.

The white line, white glow also appears around blue, green and other colored letters and on other colored paper/backgrounds. See the white glow on the blue sky above mountains, trees. Shift back and forth on the mountains, trees and sky and see the glow flash. The glow can also be seen around a person, especially the head. It can be different colors. Scientists, religions state a aura, energy field can appear.

It is well for each patient to test his ability to concentrate, stare at on one point of a large letter or of a small letter. In less than a minute the patient suffers fatigue, pain, imperfect sight. When concentration causes trouble, common sense would suggest that the concentration be avoided. Shift from point to point for clear vision.

Most cases of imperfect sight are cured by relaxation - relaxation of the mind, relaxation of the nerves of the head and of all other parts of the body. The importance of the control of relaxation is very great, because most diseases of the eyes are caused by the stare or strain and cannot be cured until the stare or strain is relieved.

## Case Reports

A girl, twelve years of age, was brought to the office by her mother who complained that her daughter was suffering from a high degree of **progressive myopia**, and that her glasses had to be changed quite frequently because of this fact. She said that she did not want to buy any more glasses because each pair had to be changed after a few months. When I tested her glasses, I found that she was wearing Concave 12 D.S. After she had been under treatment for some time, her mother said that the girl did not see the Snellen test card, but that she committed it to memory. To satisfy the mother and to obtain some facts, I showed the daughter a strange card. Although it was placed more than fifteen feet away, she read every letter correctly, much to the surprise of the mother.

When the daughter was asked how she did it, all she said was "Starch." The mother asked her why she answered so queerly. Then I told the mother that I had trained the girl to improve her sight by the use of a perfect imagination or memory. When she remembered or imagined things perfectly she always had perfect sight. She must have remembered the starch perfectly white in order to become able by the memory of starch to see the letters on the strange card perfectly. The mother then said to me: "I wish you would speak to her about the way she goes downstairs; she runs down three steps at a time and I am very much afraid that she will stumble and hurt herself." I spoke to the girl about this and she told me that while she was going downstairs, three steps at a time, she remembered a piece of white starch. **The memory of the starch gave her a perfect balance so that she was always certain of the steps that she took. The memory of starch or a white handkerchief freshly laundered has helped other people to improve their vision immediately.**

A man, aged 51, had worn glasses for hypermetropia and for reading for 20 years. Without glasses his vision at fifteen feet was 15/200. He was told to imagine a thin white line between the white spaces of the Fundamental card. In about five minutes the patient became able to remember or imagine a thin white line when regarding the white spaces between the lines of black letters. By repetition and some patience he became able to read diamond type at six inches. After this was accomplished, his vision for distance became normal and he read the bottom line without trouble at fifteen feet.

## Eye Injuries

By Emily A. Bates

It is not always easy to treat a case where the sight has become impaired through an accident or injury to the eye. I have in mind particularly two patients who came to me recently, and who at one time had had normal vision.

One was a young man, 23 years of age, who had been to several doctors for treatment during a period of ten years, and as he explained his case to me, I realized how despondent he was, fearing that he would go blind completely. He was thirteen years of age when he was taken on a long automobile trip, at which time the accident occurred. Being far away from civilization, it was some time before he was able to receive medical aid, and during that time his vision became very poor in both eyes. Some of the occupants of the car were instantly killed. He was found pinned under the overturned car, some days after the accident and after he had recovered consciousness he found that he could not see well. His head had been cut very badly and the doctors feared that internal injuries on his head and other parts of his body would prove fatal, and for a time it was thought that he would lose his mind as well as his sight. When he came to me, there was a scar on his forehead directly over each eye, but otherwise he showed no outward signs of injury.

He had received a different kind of treatment from every doctor who had treated him with the result that he did not go blind entirely. He got along very well with the aid of glasses for a time and then **cataract began to form in each eye**. An operation was advised but the boy refused to submit to this. Friends cared for him and helped him with his education but his sight was too poor to aid him in doing any kind of work which would require the use of his eyes. He stopped going to doctors for help because each one who had treated him advised an operation for the removal of cataract, with the exception of the last doctor who had given him medical treatment. This doctor knows Dr. Bates very well and has from time to time cured headaches and other pain by the Bates method, although he is not an eye specialist.

At the advice of this doctor, the boy came to me for treatment while I was in the West. The cataract could easily be seen by the naked eye, but there was a small spot about the size of the head of a pin in the retina which was clear. Not being allowed to use my retinoscope in California, in the absence of a doctor, I asked him to bring me a written statement from a specialist who had given him a thorough examination of his eyes. He replied that he had already been to one and explained that the doctor had said that

there was no hope of his ever regaining his sight. He gave me a written report from a few of the doctors who had examined him and each one had given him a different diagnosis, but all of them said there was no hope of his ever seeing again, unless he submitted to an operation, which would probably be useless.

Sometimes I have to spend a considerable amount of time convincing a patient that I can really help him, if he can have enough confidence in what I am able to do, but this young man did not need any explanation, for I seemed to be his last hope. He did not ask me for an opinion, but just came at the advice of his family physician. He felt that I really could help him if there were any chance at all.

I placed a large test card five feet from his eyes. I thought I would use the **black card with white letters first, because this card seems easier for the partially blind patient**, or those patients who have diseases of the eye, such as glaucoma, atrophy of the optic nerve, and so forth. Before I placed the card in position at five feet I had told him to close his eyes to rest them because all the while he had been in my presence, he stared hard to see me and seldom blinked his eyes. I placed the test card with the blank side of the test card facing him. There was only a plain white surface to look at and I was hoping that he would see it as it really was. When he opened his eyes, at my suggestion, he was waiting for me to tell him what to do while he looked at the blank side of this card. I asked him if he could see any letters on the card and he said, "No, it seems like a blank white paper."

I was pleased that he saw the card as it really was, without my telling him. I told him to close his eyes immediately and while his eyes were closed, I turned the card right side up. I told him to open his eyes and tell me what he saw. He was able to read three lines of the test card immediately. I encouraged him then and told him that if he were willing to sacrifice his time that I surely would give him my time to help him to improve the little vision he had.

After he palmed and improved his memory by reciting history, which was his favorite subject at school, he read the card again for me, and this time his vision improved to 5/30. I gave him a test card to practice with at home and told him to report to me in a few days' time.

Seven months later he came again for treatment. His eyes looked much better and his face showed signs of relaxation, which were absent at his first visit. I tested his sight again with the same black card with white letters and his vision had improved to 5/20. He reported that he had practiced two hours in the morning and two hours in the evening every day since his first visit. He remembered what I had said to him about **blinking his eyes consciously all the time in order to avoid the stare which made the cataract worse.**

I placed him by a window and told him to look across the street where there was a large sign with letters that looked to be about three feet in height. He said he could not read any signs from the window. I gave him a **fine print card to hold in his hand and he looked at the white spaces below the lines of black type** that were on the small card. I told him to look at the white spaces and then to close his eyes and to imagine the white whiter than he saw it on the card. He did this alternately for about five minutes and when he looked out of the window to where this large sign was, he began to see the letters one by one by quickly looking away, after seeing each letter as I directed him, and taking the sun treatment as he stood by the window, which I thought would help him. Without giving him notice, I told him to turn around with his back to the light and to look at the test card which was five feet away, and he read another line of the test card at 5/15.

I gave him the **Fundamental card** to read, but all he could see was sentence Number 1 and the words "Fundamentals by W. H. Bates, M.D." All the rest of the card was a blur to him. He knew there were words on the card, but he could not distinguish them.

Not far away from my office there was a public park where he would sit for hours at a time to take sun treatment. The warmth of the western sun is the most healing thing in the world in cases where the sun is helpful. I can prove it by this particular case, because the next time my patient came, he was able to read the whole of the Fundamental card up to sentence Number 15, which is in **diamond type**. He did not read it immediately as one with normal sight would have done, but with many hours of patience on my part and with the aid of the **sun-glass treatment** in between times he finally read it. Sometime later he came for another treatment and this time he read the **microscopic type** I gave him, which is a reproduction of that contained in the small Bible. He read this type at nine inches from his eyes. I then tested his sight for the large test card and his vision had improved to 7/20, and later 7/15 by **palming** and the **long swing**.

He left the West for other parts and I did not see him again but I received a letter sometime later, saying that he was still practicing with the test card and also with the fine type every day. After that, however, I lost track of him. There is not much satisfaction in treating a case like that unless we can cure it, but I hope that wherever he is that he is still keeping up with the Bates treatment and receiving benefit. At any rate, I was very much encouraged to know that the Bates Method helped when all else failed, and that I was able to improve his vision, instead of saying as others had said to him that there was no more hope.

The other case which was interesting to me was a young man, twenty years old, who had started to wear glasses at the age of ten years. He had been playing with some boys near a building that was being torn down and without realizing it the boys were playing near a section of a wall which was about to come down. It finally did tumble down and buried them under a mass of debris. **The boy's glasses were broken and the right eye was severely injured, having been cut by the broken glass.**

His father was a physician and he took him to various eye specialists in the hope that the left eye could be saved. For some time the left eye was discharging and he almost lost the sight of it. With medical treatment and care the discharge ceased and apparently there seemed to be nothing wrong with his left eye. He strained terribly in daylight, but at night he had very little trouble in seeing things. Since the accident he had acquired the habit of turning his head to one side and squeezing the lids of his right eye together tightly, in order to see with the left.

Before I tested his sight with the test card he told me that there was a dead nerve in the left eye which was caused by the injury to the right eye—at least he was told by the eye specialists that this was so. After the accident he said that he had had an attack of malaria, and then keratitis settled in both eyes. At the age of fifteen he suffered a great deal of pain in his right eye and was treated for iritis.

After listening to all he had to say, I tested his sight. He could only see the large letter "C" of the test card at six inches from his right eye. Everything else was a blank to him. His vision with the left eye was 15/20, and all the letters were clear and black. In order to read with the left eye, he turned his head to one side. I told him to palm and reminded him that he must not remove his hands from his eyes while I was talking to him. I told him that no matter what the diagnosis was or how bad his sight was that he could at least see something on the test card with his right eye and that I did not believe that there was anything radically wrong with his left eye. If there were, he could not have seen the 20 line letters of the card at fifteen feet.

I gave him some **sun treatment after he had palmed** a little while and then told him to **palm again** before I tested his sight the second time. I felt that it was necessary for him to close his eyes and palm after being in the bright sunlight.

This poor fellow had quite a story to tell me and I had a strong desire to become better acquainted with him and help him in other ways besides improving his sight. He was not a nice looking boy and neither was he clean. He did not wear a coat or vest and he

had no hat with him when he came. His shoes were soiled and much worn and he looked as though he had not received much affection or care for a long time. He was short in his answers and when he looked at me, he would just look for a moment and then look away. I told him that I believed that he was far away from his home, but that he was not the only one, and that I was three thousand miles away from my home too.

While he was palming, I noticed a tear drop on the front of his shirt and then I encouraged him to tell me all about everything that was on his mind. I told him I wanted to be his friend if he would let me. He told me that he was sad and lonely too and that his family no longer cared about him. He said that it was his own fault, of course, but a strict father whose confidence he never had made it hard for him to live at home. He said that he did not know what was the matter with him, but that he could never hold a job for any length of time. He knew there was something wrong with him but he did not know how to become better and he had no one to guide him.

I asked him if he had a home somewhere and he said "Yes." He said that a distant relative had befriended him and given him a place to sleep. What I had to say to him that day helped, I know, because the next time he came his shoes were cleaned, his top shirt had been washed and ironed and his face and hands were clean. We became friends after that and up to the last week of my stay in the West, I helped him with his sight and in other ways. As his vision improved, he obtained a position in an office which paid him a fair salary. Every day he arose early in the morning to practice with the test card and before retiring at night he practiced again. During the day he remembered what I had advised him to do with the **small pocket test card and microscopic type**. He practiced the **long swing and palming** which always helped to improve his sight, and on the last day I saw him his right eye had improved to the 50 line of the test card, as he held the card at two feet from his eyes. His left eye improved to 12/10 which is more than normal vision.

I have had no further report from this patient, but I am confident that he has not forgotten what to do to avoid the loss of vision in his right eye.

If this patient I have written about reads this article, he will know who I mean. I hope that if at any time he visits New York he will come to see me if he needs more help for his eyes.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JUNE, 1929

### Go To The Movies

(Editor's Note. - Recently a great many letters have come from patients and others asking if the movies were injurious to the eyes. For the benefit of these inquirers we are reprinting an article which appeared in this magazine in October, 1920.)

Cinematograph pictures are commonly supposed to be very injurious to the eyes, and it is a fact that they often cause much discomfort and lowering of vision. They can, however, be made a means of improving the sight. When they hurt the eyes it is because the subject strains to see them. If this tendency to strain can be overcome, the vision is always improved, and if the practice of viewing the pictures is continued long enough, nearsight, astigmatism and other troubles are cured.

If your sight is imperfect, therefore, you will find it an advantage to go to the movies frequently and learn to look at the pictures without strain. If they hurt your eyes, look away to the dark for a while, then look at a corner of the picture; look away again, and then look a little nearer to the center: and so on. In this way you may soon become able to look directly at the picture without discomfort. If this does not help, try palming for five minutes or longer. Dodge the pain, in short, and prevent the eyestrain by **constant shifting, or by palming**.

Shift on objects; object to object, part to part, small point to small point. Shift on/see fine details clear. Blink, breathe abdominally and relax. Trace objects and parts of objects with the Imaginary Nosefeather. See diagram last pages this book.

Bring an eye patch to the movies; Practice shifting, tracing, central fixation on the objects, parts of objects, people on the screen with both eyes, then with one eye at a time, then both eyes together again.

Then just relax, forget about the eyes and enjoy the movie.

Practice this shifting, tracing, central fixation... both eyes, one eye at a time, both eyes together again, on any objects in your environment; close and distant.

If one eye needs more vision improvement, practice a while longer with that eye. Often correcting less clear vision in one eye; clarity of vision, eyes movement for shifting, central fixation, switching close and far - convergence, divergence, accommodation, unaccommodation is all that is needed to bring the vision in both eyes to 20/20 and clearer. This is basic 'Behavioral Optometry applied with the Bates Method' and is often not emphasized enough in many vision improvement courses.

When switching close and far on objects is taught, Optometrists would forget to teach the person to also shift on the object the eyes are looking at. Shifting and central fixation on the objects must be done when switching, looking at close and far objects.

## Cataract

By W. H. Bates, M.D.

Sinbad the Sailor Story, How Goats Perform Their Own Cataract Operation

Sinbad the sailor told many stories of his voyages which have pleased some adults and many children. I wish to maintain that some of his experiences were true while many were not. On one of his voyages, when sailing in the tropics, a violent storm struck the ship and he was wrecked on the shores of an island in the Pacific Ocean. As usual, most of the sailors were drowned but Sinbad lived to return home and tell of the wonders he had seen.

It was related by him that the island was frequented by goats who were blind for a variable length of time. After a few days or weeks many of them recovered their sight, being cured in some way by a thorn bush which had large thorns. Sinbad watched them closely and discovered that each goat pushed each blind eye directly onto one of these thorns. After a few efforts the goat became able to see. How was it accomplished?

The cause of the blindness was the presence of an opaque body behind the pupil. This opaque body is a cataract. There are numerous operations for the cure of cataract but all are planned to move it to one side, above or below the optic axis so that the pupil appears perfectly clear and permits good sight. Eye doctors during the period when Sinbad flourished had no other cure for cataract except an operation such as the goat performed on his own eyes. It was done so easily, so quickly, and in most cases so successfully that many quacks or irregular practitioners who did not understand it failed to remove the cataract properly and the sight was not improved.

Sinbad wrote a very clear account of how the goats got rid of their cataracts. He told how a goat would, in his blindness, move his head and eyes about different parts of the thorn bush until he was able to push one of the thorns into his center of sight and push the opaque cataract out of the way.

Sinbad wrote a great deal about the failures. He described how in many of the goats which operated upon itself, foul matter would form and destroy one or both eyes. But when the goat did things right, the eyes healed without any bad symptoms whatever. Sinbad's operation for the cure of cataract was described so long ago that there are still many doctors who claim that as they had never heard of Sinbad's operation there never was such a person as Sinbad.

Modern physicians believe that the thorn is not the best instrument to use to remove the cataract in elderly people. Various and numerous operations have been recommended and practiced with good results.

An opacity of the crystalline lens which is sufficiently opaque to interfere with the vision is called a cataract. There are two kinds of cataract - hard and soft. The hard cataract occurs usually in adults. An operation for its removal is usually advised for an improvement in the sight. When the operation is done properly, the vision is usually permanently improved. After the operation is completed without accidents, strong glasses are prescribed, which increase the vision. Two pairs of strong glasses are used by the patient. One pair is to improve distant vision, while a second pair with much stronger glasses may be necessary for reading, sewing, or other close work. The Bates Method can improve vision without glasses after cataract operation and can reverse cataract and prevent the need for surgery.

Soft cataract occurs usually in children or in adults at the age of 45 or younger. One operation is called "needling," in which a needle or very sharp knife penetrates a small part of the lens. A slight opacity of the lens may be seen for several days or longer, which usually causes no discomfort. It is customary to wait a few days or longer until the opacity made by the operation has disappeared. The operation is then repeated as before. By alternating in this way, the opacity of the lens becomes less after each needling until the cataract has disappeared altogether. The patient uses two pairs of glasses just the same as after the operation for the removal of a hard cataract.

Who were the earliest physicians? Who were the best doctors to cure the blindness of cataract? Barbers at an early date always bled their patients to cure any disease. Their motto was to bleed the patient until he was cured.

If the first bleeding failed it was considered good practice to bleed him some more. George Washington met his death at the hands of the barbers from too much bleeding. In the treatment of cataract in modern times we do things which are not always considered to be proper. At one of the best eye hospitals in this country patients suffering from severe pain and loss of sight have been bled from the temples and elsewhere and lost much blood that I considered unnecessary. While bleeding has apparently in some cases been a general benefit, this method of treatment is seldom indicated in a large number of patients.

Cataract occurs in a small percentage of persons with imperfect sight. One and the same method of treatment for all cases of cataract is not advised. It has been demonstrated and frequently published in this magazine that **the cause of the opacity in the lens is a strain, a stare, an effort to see. When the strain is removed by relaxation methods, the cataract disappears and good or perfect sight is obtained without an operation of any kind.** This being true, the removal of the cataract by some sort of an operation is the same as it would be to amputate the foot to cure rheumatism of the big toe.

People with cataract in one or both eyes may suffer from rheumatism, diabetes, bladder trouble, or other serious diseases which make it impossible for them to travel on land or water. Headache is sometimes continuous and of great severity. These patients may become bedridden and unable to walk without distress. The heart is often inflamed to such an extent that the slightest exertion brings on severe symptoms.

Some years ago a very intelligent Spaniard called to see me in reference to treatment of his wife who was a very sick woman and had been bedridden for many years. Her vision was very poor. She was unable to count her fingers when held in front of her face at a distance of two feet or more. The husband was told that it would be better for his wife to be cured of cataract while she was at home as the trip to New York would probably cause her so much discomfort that it would be very difficult to cure or improve her cataract by treatment. I told him that it would be possible for him to learn relaxation methods and have his wife practice them under his supervision. The fact that he himself had good sight would enable him to treat her more successfully than someone who had poor sight. He accepted my suggestion and told me that he would faithfully carry out any treatment which I might suggest.

The first thing I had him do was to:

**+Read the Snellen test card at fifteen feet with each eye separately.**

**+Then he was directed to stand with his feet about one foot apart and to sway from side to side, while facing the Snellen test card. He learned how to do this very quickly. His attention was called to the fact that when the Snellen test card appeared to move in the opposite direction to the movement of his head, eyes and body, that the white card**

Adventures of  
Sinbad the Sailor

appeared whiter than it really was. The black letters also appeared much blacker and more distinct than when he did not practice the sway.

+He was then told to close his eyes and by opening and shutting them alternately, his vision improved.

+With his eyes closed he was able to imagine a small letter just as black as a large one and to imagine it better with his eyes closed than with his eyes open. When he imagined a small letter at the beginning of a line of letters perfectly black or as black as the larger letters, his vision improved to better than the average sight.

I examined his eyes with the retinoscope and found that the memory of imperfect sight caused the area of the pupil to appear blurred. When he strained or made an effort to improve his sight, the area of the pupil became very cloudy, the eyeballs became hard and the vision worse - a condition similar to that which occurs in cataract. This man was told that with his good sight he could at will increase the hardness of his good eyeballs more readily and lower his vision more readily than his wife who had cataract.

It is a truth that persons with normal eyes can produce imperfect sight at will to a greater degree than when the sight is imperfect from cataract. A large number of patients with cataract have been examined with the retinoscope at the same time that a strain is made to improve the sight. In all cases without exception the cataract became worse by an effort to see and the vision was still further lowered. Many persons with normal eyes were also examined at the same time. An effort to see better lowered the vision to a greater extent than occurred with the patients suffering from cataract.

It should be emphasized that a stare or strain is the principal cause of cataract. The retinoscope demonstrates that when an effort is made the cataract becomes worse. When the patient remembered or imagined letters or other objects the cloudiness and imperfect sight disappeared. An important point is the readiness with which an eye with good sight is able to produce imperfect sight while one with imperfect sight has great difficulty in straining sufficiently to increase it.

The husband was very much pleased because it seemed to him that there would be more difficulty in teaching his wife how to increase her cataract than to lessen or cure it. In due time I received a very grateful letter from him; he was much pleased to inform me that his wife had cured her cataract by my methods and after the cataract was cured, she became able to leave her bed. (She had been bedridden because of fear of walking about because of her poor eyesight.) The method was a benefit not only to her eyes but to her general health as well.

### Man 106 Years Old - Vision Cured of Cataract by Bates Method

We have received many letters of inquiry from patients who have cataract who ask the questions: Can people eighty years of age be benefited? Which are the best methods of helping cataract? These questions were answered by the results of treatment in a man who was 106 years old. He came to the clinic with cataract so far advanced in each eye that he was unable, even with strong glasses, to read ordinary type. He was treated by rest of his eyes with the aid of shifting, swinging, memory, and imagination. After the first visit, he became able to read large print without glasses. His vision rapidly improved so that after some weeks of treatment, the cataract had disappeared and his vision for distance became normal. It was interesting to watch his cataract disappear while he was forming mental pictures of the white spaces between the lines of black letters.

Many patients with cataract who knew about this old man asked me how it was that he was cured in so short a time while many younger patients were not cured so quickly. The word obedience suggests that the reason this patient obtained so prompt and permanent a cure was because of his ability to obtain perfect relaxation of his eyes and mind as well as all the nerves of his body. For example, when he was told to close his eyes and keep them closed until told to open them, he did this thoroughly and well. Too many of my cataract patients do not practice central fixation as obediently as did my elderly patient.

So many people with cataract, when they close their eyes, feel that they are doing what they were told and cannot understand why they obtain so little benefit. Closing the eyes is not always followed by relaxation and rest. In short, there are many patients with cataract who strain their eyes more when they are closed than they do when they regard letters and objects with their eyes open. These patients are directed to practice the universal swing, the long swing, the variable swing and other methods of obtaining relaxation. One of the best methods of lessening cataract is to encourage the patient to regard a blank wall of one color. When the eyes are examined at the same time, it is usually found that the cataract has become less because the eye is not straining to see any one particular object.

Some cases of cataract acquire the ability to read without glasses very fine print held a few inches from the face. When such patients are recommended to read the fine print many hours daily, the cataract becomes less and the vision improves. The practice of regarding fine print or other small objects is one of the best methods of curing cataract.

### Itching Of The Eyelids and Presbyopia

By Emily A. Bates

Itching of the eyelids is sometimes a difficult thing to relieve. When a patient is troubled that way, Dr. Bates usually prescribes a salve and eyewash or eye drops to relieve the condition. Usually, such applications help, but there are times when a patient is troubled for a long period without much or any relief.

A middle-aged woman came to me in a highly nervous state and told me that she had been to several doctors, but they could only give her temporary relief. The doctors had given her exactly the same prescription that Dr. Bates usually prescribes for such a condition. Before coming to me as a last resort, she tried wearing dark glasses, thinking that she would find relief that way. Wearing the dark glasses indoors only aggravated her trouble, but while she was in the sunshine she felt relief most of the time.

She was a business woman and managed a summer hotel which kept her indoors most of the day. She was called upon at times to do some bookkeeping and after she had worn the dark glasses for a while, she discovered that she could no longer see at the near point. The last doctor whom she had called upon diagnosed her case as presbyopia, but he did not say what had caused it. He told her that at her age she had to expect a change in the condition of her eyes. He advised her to wear the glasses he prescribed for her only when it was absolutely necessary, and if that would not help to come and see me.

I had benefited the wife of this doctor and I am greatly disappointed that I did not have an opportunity to meet him before I left the West where I was taking care of patients. I tested the patient's vision for the distance and she read 15/15 with much effort and

squinting of her eyes. She squinted her eyes most of the time in order to see without discomfort. I gave her the Fundamental card to read. The type on this card starts with larger than ordinary reading type and ends with diamond type, which is much finer than ordinary type. She held this card at arm's length and then drew back her head as far as she could in order to read the diamond type on the card. She could not understand how I could bring back her sight to the normal by our method of eye training. Before she came to me she believed that proper glasses would eventually relieve her of all her trouble, but that she would have to wear glasses at all times as long as she lived.

After a doctor friend of mine had examined her eyes, and diagnosed her case as presbyopia caused by strain, he asked me to examine her eyes with his retinoscope and verify his statement. The itching and burning of her eyelids had nothing to do with her sight. Sun treatment sometimes instantly relieves itching of the eyelids and also does more sometimes than medicine applied to the eyes. I placed my patient in the sun and while her eyes were closed I focused the strong light of the sun on her closed eyelids with the aid of the sun glass. This was done so quickly that the patient did not realize what I was doing.

Immediately after I used the sun glass I placed my hand before her closed eyelids to shade her eyes from the sun. Then I placed myself between my patient and the direct rays of the sunlight and asked her to open her eyes. She began to blink in a natural way as she looked at me and remarked how differently everything looked about her. She sighed with a sense of relief and asked me to do it again.

The second time I applied the sun glass she could stand the strong rays of the sun for about a minute and then I again placed myself between the sunlight and my patient's eyes. Again I told her to open her eyes and look at me, but this time I held the Fundamental card before her, about twelve inches from her eyes. She read Number 3 or the third sentence on the card and then her eyelids began to itch again. The sun treatment was repeated for an hour, while she alternately read the Fundamental card and she read two more sentences, without noticing that she was gradually reading smaller type.

The patient was pleased with her first treatment and came daily for a week and each time her vision improved for the near point and the itching and burning of the eyelids became less.

**We seldom advise patients about the amount of water that they drink, or the kind of food that they eat, but this patient had brought up the subject herself. My experience for many years with clinic patients has taught me much about the mistakes people make in eating the wrong food and not drinking sufficient water. I feel quite sure that my patient's assistance and intelligence about eating unseasoned foods and drinking a large quantity of water every day helped to cure the irritation and discomfort of her eyes.**

I did not cure this patient in a week's time but at the end of one week's treatment, after I had seen her for the last time, the presbyopia was entirely cured and she read microscopic type in bright sunlight as well as she could read ordinary type at six inches from her eyes. When reading microscopic type, she had to have a strong, artificial light, or place herself directly in the sunlight in order to read it. By looking at the white spaces of the diamond type, which is a little larger than microscopic type, she became able to see the white spaces between the lines of microscopic type and in this way, she was able to read it.

Like most people who have trouble with their eyes, she seldom blinked, which she thought was an affliction instead of a natural thing to do. While I did not like the discomfort that staring caused me, I purposely stared or blinked less frequently than I ordinarily do, as she stood before me. It helped her to understand how **necessary it was to blink often and to do it continuously, in order to form the unconscious habit of blinking**, when she no longer had trouble with her eyes. She noticed that when I blinked my eyes that the eyes moved slightly and when she began to practice this, she said that the burning of her eyes and itching became less. **She made a mask from a large linen handkerchief and only exposed her eyes when she placed herself in the sun.** She would sit in the sunshine for an hour at a time each day while her eyes troubled her. At the end of seven days, giving her daily treatment, her trouble disappeared entirely.

On the seventh day, I returned the dark glasses which she had placed in my possession, so that she would not be tempted at any time to wear them while under treatment. I asked her to put them on while she was sitting in the sun and tell me how she felt with them on. She said it seemed as though the world had become dark, without any sunlight. While she was talking to me, the discomfort she felt while the glasses were on was such that she threw them off quickly and said she did not want to use them again.

There comes to my mind a clinic case which I would like to report now. A woman who seemed fairly well dressed brought her little boy to the clinic and as he appeared before me, I noticed how shabbily he was dressed. His hair looked as though it had not been combed for many days and from the appearance of his little hands it seemed to me that soap was almost an unknown thing to him. The poor little fellow was about eight years of age or perhaps younger.

While I was giving my attention to some of the children who were having their eyes tested with the test cards, he came close to me and watched every move I made. His mother was holding his hand and as he moved closer to me, she drew him away, none too gently. A thought passed through my mind instantly that surely this was not his mother. He looked so shabby and dirty and she looked just the opposite. Dr. Bates placed him in the little dark room where all the patients had their eyes examined and after he had finished examining the little fellow's eyes, he called my attention to the condition of his eyelids, which I had not noticed before.

His eyesight was normal. There was nothing wrong with the retina, but the **cornea and sclera or the white parts of his eyes were much inflamed. The eyelids of both eyes were much mattered.** Dr. Bates asked him what his greatest trouble was and he said his **eyes itched all the time and even at night the itching prevented him from sleeping.** Dr. Bates questioned the little boy's mother and asked her how long he had had this trouble. She said she had noticed him rubbing his eyes for a few weeks or longer, but did not pay any attention to it until his school teachers sent him home to be examined by the Doctor.

We placed him in a good light and as the Doctor focused his magnifying glass on the eyelids, he drew back suddenly and asked me not to touch the boy's eyes. On a slip of paper, the Doctor wrote the word "**parasites.**" The mother became enraged when the Doctor diagnosed the case as such. My heart went out to the little fellow. I did want to take him away from a mother who cared so little for her child. Dr. Bates advised the mother not to have anyone else use his towel or wash cloth and he directed her further to use an eye wash he prescribed and a salve to be applied afterward and to come regularly every clinic day until he was rid of his trouble.

Apparently the directions for his treatment at home meant time and attention which she did not care to give for the little fellow. Before we realized what had happened, the mother had left the clinic and we did not see her or her little boy again. We reported this case to someone in authority at the clinic who was to send a social worker to the home of the little boy. What became of the case we could never find out, but for the sake of any child who may be afflicted or become afflicted as this little boy was, I decided to tell about this case, so that mothers of public school children who might possibly read this article will know what to do to help their

White cloth over head, face. Eyeholes for sunning without getting sunburn on the skin.

children.

If the mother cannot afford to visit a physician at his office, she can always find a competent one at any eye clinic and receive treatment with permanent benefit. Sometimes through no fault of the mother or child, a thing like this happens and it seems out of nowhere that this **contagious thing strikes even the cleanest and well cared for children**. The itching in this condition is terrific. If the trouble is noticed and looked after in time, it can be easily cured by treatment. As Dr. Bates explained this condition to me, he said that he did not believe that he nor any doctor can tell where such things originate. We do know, however, that cleanliness helps to eliminate the trouble.

## Questions And Answers

Q - After palming for ten minutes or longer, my eyes are rested, but I feel sleepy.

A - The palming is not perfect. Try imagining stationary objects to be moving when you palm.

Q - Are memory and imagination the same? When we remember an object do we have to visualize it?

A - A perfect memory cannot be obtained unless you are able to imagine that you see or visualize what you remember.

Q - Please give me a simple demonstration or example of the swing. I cannot see objects moving when I know they are stationary.

A - When you ride in a railroad train which is traveling fast, and look out that window, you may see the telegraph poles and other objects moving in the opposite direction.

Q - My little son, four years old, becomes fidgety while palming. Do you prescribe something else equally beneficial?

A - Your little son may become able to palm for a few minutes at a time. Swaying from side to side usually helps.

Q - How can one overcome the stare if it is unconscious?

A - Blink consciously, whenever possible, especially when reading. Never look at an object for more than a few seconds at a time. Shift your gaze.

Q - (a) My eyes are swollen and disfigured in the morning. (b) Although I have eight and nine hours' sleep, it does not rest me.

A - (a) The swelling of your eyes or eyelids in the morning is due to eyestrain when you are asleep.

Read chapter in my book on this subject. (b) You may be restless and sleep very poorly and strain your eyes terribly, although apparently you may be asleep for a long time.

Q - When palming and remembering black, is it advisable to keep the image stationary and to keep the same image, or is it just as good to shift from one object to another?

A - When palming and remembering black, one should imagine everything remembered to be moving and not stationary. It is necessary to shift from one image or from one object to another.

Q - What is most helpful when one is very nearsighted and finds it almost impossible to see without glasses?

A - Practice palming as frequently as possible every day. Keeping the eyes closed whenever convenient for five minutes ten times a day is also helpful.

Palm and remember, imagine a pleasant object, scenery and shift throughout the scene; from object to object, part to part on objects. See objects in motion, action like a real life movie in the mind, in color, clear.

Palm and Imagine perfect black or any pleasant thought, memory, object, scene.

Right eye, Right hand Left eye, Left hand

Elbows rest on pillow for good, relaxed posture

Left hand over the left eye first. Then right hand over right eye and right hands fingers cross over on top of the left hands fingers in the center of the forehead.

### Mental Pictures

E

Perfect imagination of clear mental pictures improves eye health and clarity of vision.

Shift on the E, tree, flower in the mind, imagination. See them clear, in color. See 'The Swing' of opposite movement when shifting on a object.

With imperfect sight, a mental picture of one known letter of the Snellen test card is seldom or never remembered, imagined, or seen perfectly when regarded with the eyes open. By closing the eyes, the same mental picture may be imagined more perfectly. By alternately imagining the known letter as well as possible with the eyes open and the remembering it better with the eyes closed, the imagination improves the vision and unknown letters are seen with the eyes open.

The improvement of the vision is due to a lessening of the organic changes in the eye. When the imperfect sight is caused by **opacities of the cornea**, a mental picture imagined clearly lessens or cures the disease of the cornea. A large number of cases of **cataract** in which the lens is more or less opaque have been benefited or cured by the imagination of mental pictures. Nearly all organic changes in the eyeball which lower the vision have been improved to some extent in a few minutes; by devoting a sufficient amount of time, all organic changes in the eyeball, no matter what the cause may be, are benefited or cured by a perfect imagination of a letter, a tree, a flower, or anything which is remembered perfectly.

I do not know of any method of obtaining relaxation or perfect sight which is as efficient and certain as the imagination of mental pictures. It should be emphasized that a good or perfect imagination of mental pictures has in all cases brought about a measure of improvement which is convincing that the imagination is capable of relieving organic changes in the eye more quickly, more thoroughly, more permanently, than any other method.

Perfect Memory and Imagination = Clear Eyesight

Eyes open - Shift on the C and remember, imagine it clear.

Eyes closed - Shift on the C in the mind and remember, imagine it clear.

Eyes open - Shift on the C and remember, imagine and see it clear.

### Throw Away Your Glasses

By W. H. BATES, M.D.

(Editor's Note: The following is a reprint from an article which appeared in *Hearst's International*, September, 1923, which is being republished in *Better Eyesight* at the suggestion of some of our readers.)

MORE than thirty years ago, not knowing any better and being guided by the practice of other eye doctors, I recommended patients with imperfect sight to throw away their eyes and see with their glasses. Since that time I have made some valuable discoveries which have enabled me to cure people without glasses. The slogan now is: "Throw away your glasses and see with your eyes."

We are rapidly becoming a four-eyed nation. The enthusiasm of the eye doctors is putting glasses on many people who do not need them. Just as soon as we go to the doctor and complain about our eyes or some nervous trouble with our minds and our heads, the stomach or something else, the doctor prescribes glasses. Fifty years ago the number of persons wearing glasses was very much less than it is now. Human nature is such that when one person gets glasses we believe everybody else should do as we do and wear glasses. When prominent people set the fashion the rank and file feel that they must do the same. It is a matter of record in this country with a population of one hundred and ten million or more, that all persons over forty years of age, according to the old theories, should wear glasses.

Some eye specialists have gone so far as to say that all children attending school should wear glasses either to relieve imperfect sight or to prevent their eyes from failing. This matter was considered by the Board of Education of the City of New York in 1912 and much pressure was brought bear to have it done. I was the only physician that went before the Board of Education and recommended the method of treatment which had cured and prevented imperfect sight in school children without the use of glasses.

The craze for glasses has even included nursing babies. It is all wrong, and the evidence has been accumulating through the years that imperfect sight is curable without glasses. Most of us should have an interest in the welfare of every child and get busy and investigate the facts. The medical profession has neglected its duty. They have done noble work in the study and prevention of yellow fever and other conditions, but when it comes to the eyes the doctors can only recommend glasses. My investigations have demonstrated many facts of great practical importance.

In the first place all children under twelve years of age with imperfect sight can be cured without glasses. This is a challenge. If there is one child who cannot be cured by my treatment I am wrong about the whole thing. There is no exception and when a proposition has no exception we call it a truth.

They can be cured not only by me but by their parents, by their teachers, by anybody who has normal sight, but they cannot be cured by people who have imperfect sight. The teachers in the public schools have succeeded by practicing my suggestions with the children, reading the Snellen test card with each eye as well as they can every day, devoting in most cases only a few minutes daily. Those children whose sight is already normal only need to read with normal sight, one minute or less, every day to prevent eye-strain and imperfect sight.

One day I visited a classroom and I said to the teacher: "Can you pick out the children who have imperfect sight?" She selected a number of children that she thought had imperfect sight. In every case her selection was made because of the way the children used their eyes. Some of them squinted, some of them strained in other ways.

I tested the sight of these children and found it imperfect. Then I suggested to the teacher that she ask the children to use their

eyes without strain, without making any efforts to see. I said, "You will find how well they can see when they use their eyes easily, without effort".

Much to her surprise they all read the card with normal vision. Some of these children were wearing glasses. When they removed their glasses at first their sight was imperfect but after resting their eyes by closing them for five minutes or longer their vision became very much improved. In one classroom the teacher found that all her children had imperfect sight; but by showing them how to rest their eyes, by avoiding the strain, and by closing them, the vision of all of them was improved and all obtained perfect sight except one. I learned that this one also obtained perfect sight a few weeks later. It is impossible to cure those children while they are wearing glasses.

In all my enthusiasm I felt that it was not proper for me to interfere with children who were under the care of a physician while wearing the glasses he prescribed. Of course I could not be blamed if the children lost their glasses and got well without them.

It should be emphasized that teachers wearing glasses have a larger percentage of pupils with imperfect sight than have the teachers whose sight is normal and who do not wear glasses. Why is this? The facts are that children, being naturally great imitators, not only consciously or unconsciously practice the strained look of the eyes of the teachers with imperfect sight, but also the strain of all the nerves of the body. For the benefit of the school children no teacher wearing glasses or who has imperfect sight should have charge of children in any public or private school.

Parents wearing glasses are under a nervous strain almost continuously. It can be demonstrated in all cases that the children's eyes tend to strain and that the sight becomes imperfect because most children, if not all, imitate consciously or unconsciously the nervous strain of their parents. The future of our country is in the hands of the children and I believe that we should all make any sacrifice which can be made for their welfare.

It was demonstrated that all persons I tested wearing glasses were curable without glasses. I have demonstrated this fact, that the eyes of all near-sighted persons become normal while looking at a distant blank wall without trying to see. The same is true in all other cases, in far-sightedness, in astigmatism; there are no exceptions.

**It can always be demonstrated that when the normal eye with normal sight makes an effort to see at the distance the eye becomes near-sighted; again, no exceptions. When the normal eye strains to see at the near point the eye tends to become and does become less near-sighted and produces a measure of far-sightedness.**

The strain in astigmatism can always be demonstrated. One can by will produce in the normal eye any kind of imperfect sight by the necessary strain. The normal eye is always at rest and nothing is done in order to see. If anything is done it is always wrong and always produces imperfect sight. This suggests treatment and prevention. Treatment can only succeed when perfect rest is obtained.

Every physician wearing glasses, like every child, every man, every woman, has to strain to make his eyes fit the glasses. In every case this fact can be demonstrated. Surely the leaders in this movement for the benefit of the eyes of the school children can be or ought to be the medical profession, and I feel that we are lax in our duty when we neglect to study these methods and practice these methods which cure imperfect sight without the aid of glasses.

Imperfect sight is usually contagious. Actors on the stage do not feel the need of glasses. Fancy some operatic star going through a performance wearing strong glasses. The strain would spoil the music.

#### Sunlight

Many people are afraid of the light. They protect their eyes with dark glasses when they go to the seashore, they use umbrellas, sunshades; in tropical countries special kinds of hats are popular, hats which are supposed to prevent the bad effects of the sun.

Bookkeepers and people who work by artificial light wear contrivances of all kinds to shade their eyes from the artificial light. Is sunlight injurious? It is not. Of course after remaining in a dark room and suddenly going out into the bright sunlight one feels the change, and if one is at all nervous the effect of the light on the eyes is magnified—exaggerated. Some people believe it injures the eyes to read in the bright sunlight with the sun shining on the page. They complain that the light dazzles their eyes.

I know a farmer who for fifteen years had never been able to do a stroke of work out in the sun. He complained that the light blinded him and so he remained in a dark room most of the time and was not as happy as he might have been. He had a large family and in their sympathy they believed as he did and all the time cautioned him to protect his eyes. If someone opened the door suddenly and let in the daylight there was a great rush to close the door and protect the gentleman from the light.

He came to me with his eyes well wrapped up and protected from any light striking his eyes. I darkened the room and had him look down, and when he looked far down I lifted the upper lid and focused a strong light on the white part of his eye—first the artificial light and then the strong light of the sun.

The effect was miraculous. He smiled and walked around the room, looked out the window, put on his hat and walked down the street and came back feeling first rate. Ever afterwards he enjoyed the light instead of suffering from it. All he needed was a little encouragement. Focusing the strong light in his eyes with the aid of the burning glass and doing it right caused him no pain or discomfort whatever.

I know a white man who lives in Borneo, an island in the tropics. This man goes around **without a hat**. He told me that the natives did not wear hats and had no discomfort from the sun and what was good enough for the natives was good enough for him, and it certainly worked. He has lived there forty years or more and the sun does not do him any harm. Did he ever suffer sunstroke? No. Did anybody else ever suffer sunstroke in Borneo? There is no record. Out in the Canadian northwest in the summer time the sun is very strong and the crops mature in a few months. They raise fine wheat there. Do you hear of anybody being sunstruck working in the wheat fields?

In New York City the papers publish records of sunstroke from time to time during the hot weather. I have been called to attend such cases. Quite a number of people living in tenement houses have been ill during the very hot weather and I am quite sure that many years ago I believed that I was treating cases of sunstroke. It is very queer but many of these cases never saw the sun and most of them had a breath that we in the days of prohibition might envy.

I do not believe any baseball player or any tennis player in spite of his strenuous exercise on bright sunny days has ever suffered from any bad effect of the sun. Most tennis players do not even wear a cap to protect their eyes from the sun and you have to have good eyesight to play a good game of tennis. The light of the sun often shines directly into their eyes when they serve the ball and the experts are able to drive the ball quite accurately in spite of the sun.

Many years ago I listened to the older and the wiser men who treat the eye and they complained that something ought to be done to prevent children playing out in the sun without any hats on. We are more liberal now and treat **tuberculosis** in children by **exposing not only the head and eyes but their whole bodies naked to the sun** and I understand it is a very successful treatment. **Miners who seldom see the sun always have disease of their eyes. All people who wear dark glasses and avoid the bright sunlight always have trouble with their eyes.**

I had a patient once who spent two years in a hospital here in New York many years ago, occupied a dark room and had her eyes

bandaged with a black cloth so that not a ray of light could possibly enter her eyes, and at the end of her treatment left the hospital worse than she was before. I cured her by having her practice looking at the sun. At first when she did it she was temporarily blinded. She said that she had no perception of light whatever, but in a few hours she recovered and her eyes felt better.

I undertook to caution her by suggesting that she do it gradually not to get too much of the sun at once, to wait until she became more accustomed to it; but she paid no attention to what I said and went ahead and blinded her eyes again and kept it up every day, with very rapid improvement in her sight, until it was not more than a week or so before she could look straight at the sun without suffering any inconvenience whatsoever. Her vision which had been one-tenth of the normal with glasses became normal without glasses after the sun treatment.

Some scientists in Boston experimented on the eyes of rabbits. They focused the strong light of the sun directly into the eyes and then examined the retina with a microscope and much to their surprise found nothing wrong. They tried strong electric arc lights and found that the retina was not injured. They used every known light on the eyes of these animals and in no case was the light ever an injury.

About ten years ago the Scientific American published a series of articles on the effect of light on the eyes and published that some of the rays were injurious. I tested the facts and found that the man who had written the article had neglected to report the exceptions.

Recently an acquaintance of mine told me that he had seen in the last three months seventy-four cases of disease of the eyes from exposure to strong light from the electric arc. I told the gentleman that he had had an unusual experience, but in my heart I knew he was not telling the truth.

## Concentration

For many years it had been drummed into my mind by my teachers when I first went to school and later by my professors in college, that in order to accomplish things and to make a success of life, one should practice concentration. Recently in New York I received an advertisement from a man who delivers popular lectures, an invitation to attend the lecture with the title "Concentration the Key-note to Success." About the same time one of my patients suffered very much from imperfect sight. The patient bought a book of 500 pages on concentration. He bought the book to improve his memory and sight.

For many years from time to time patients from the faculties of Columbia, Yale, Harvard, Princeton, Cornell and other colleges come to me for treatment of their eyes. They all say that not only are they unable to use their eyes for any length of time but that they are also ill in a great many other ways, physically, mentally, with their nerves all shot to pieces. They complain that they have lost the power to concentrate.

By investigating the facts I find that invariably they have been teaching concentration. It does me a great deal of good personally to get square with them because these are the people who cause so much imperfect sight. It can be shown that all persons with imperfect sight are trying to concentrate. I have repeatedly published and described the evidence which proves conclusively that concentration of the eyes is impossible.

Trying to do the impossible is a strain, an awful strain and the worst strain that the eyes can experience. So many people have a theory that concentration is a help and if we could all concentrate we would all be much better off. The trouble is that concentration is a theory and not fact. If you try to concentrate your mind on a part of a large letter of the Snellen test card at ten feet or twenty feet it can be demonstrated that the effort fails and the vision becomes imperfect.

The same is true of the memory and of the imagination. The dictionary says concentration is an effort to keep your mind fixed on a point. I have tested a great many people and not one of them was ever able to accomplish it for any length of time, and the result is always bad for the eyes, the memory, the imagination, the nerves of the body generally. If the professors of concentration were wise they would avoid trying to practice it. It is only in that way that they can avoid trouble.

## Treatment

If you have imperfect sight and desire to obtain normal vision without glasses, I suggest that you keep in mind a few facts. In the first place **the normal eye does not have normal sight all the time, so if you have relapses in the beginning do not be discouraged.**

It is normal for the clarity of vision to fluctuate: clear, less clear, back to clear. Avoid eyeglasses. The vision will return to normal on its own.

First test your sight with a Snellen test card with each eye at twenty feet, then close your eyes and rest them. Cover them with one or both hands in such a way as to shut out all the light and do this for at least an hour, then open your eyes for a moment and again, test your sight with both eyes at the same time.

Your vision should be temporarily improved if you have rested your eyes. If your vision is not improved it means that you have been remembering or imagining things imperfectly and under a strain. With the eyes closed and covered at rest, with your mind at rest, you should not see anything at all—all should be black. If you see colors—red, green, blue, or flashes of light—you are not resting your eyes, mind but you are straining them.

Some people when they close their eyes let their minds drift and think of things which are pleasant to remember, things which come into their minds without their volition and which are remembered quickly, easily and perfectly. Some patients have great difficulty in improving their sight by closing their eyes and trying to rest them. If you fail, get someone with perfect sight to demonstrate that resting the eyes is a help and who can show you how to do it.

When persons with normal eyes have normal sight they suffer no pain, discomfort, headaches or fatigue. When a person with imperfect sight closes the eyes and rests them successfully the eye becomes normal for the time being. When such a person looks at the distance and remembers some letter, some color or some object perfectly the eyes are normal and the vision is perfect. This is a very remarkable fact; it has been tested in thousands of cases and one can always demonstrate that it is true.

One of the quickest and most satisfactory ways of improving the sight is a perfect imagination. The normal eye at twenty feet imagines it sees a small letter of the same size as it does at one foot. The eye with imperfect sight on the contrary usually sees a letter at twenty feet larger than it really is.

The normal eye imagines the white of a Snellen test card at twenty feet, ten feet, as white as it is at one foot. The eye with imperfect sight sees the whiteness of the card less white or a shade of gray.

The white centers of the letters are imagined by the normal eye to be whiter than other parts of the card, while the eye with imperfect sight imagines the white centers of the letters to be less white than the margin of the card. Persons with imperfect sight have been cured very quickly by demonstrating these facts to them and encouraging them to imagine the letters in the same way as the normal eye imagines them.

When reading small print in a newspaper or in a book the normal eye is able to imagine the white spaces between the lines whiter than they really are. The whiter the spaces are imagined the blacker the letters appear and the more distinct do they become.

Persons with imperfect sight do not imagine the white spaces between the lines of fine print that they are endeavoring to read, to be as white as the margin of the page.

The above sentence may be a misprint or not perfectly clear.

When sight is imperfect, the person might imagine the white spaces between sentences to be as white as the margin of the page or a gray blur which is less white than the margin.

Persons with perfect sight imagine, see the white spaces between sentences perfectly clear, and as a glowing, bright, white, brighter, whiter than the margin of the page, whiter than areas of the page away from the black print. Also, the edge of the outer area of the page, the paper's edge does show a thin white, bright glowing line.

Persons with imperfect sight do not become able to read fine print until they become able to imagine the white spaces between the lines of letters to be whiter than they really are. (Whiter than areas of the white page that are farther away from the black print)

When people with normal vision have normal sight they are always able to see one letter best or one part of a letter better than all the rest. It is impossible to see a whole letter at one time perfectly. One has to imagine different parts best. Persons with imperfect sight, when they regard a line of letters that they do not read, discover that they do not see best one part of the line of letters, but rather they see most of the line a pale gray with no separation between the letters.

By Central Fixation is meant the ability to see best where you are looking. When one sees a small letter clearly or perfectly it can be demonstrated that while the whole letter is seen at one time, one sees or imagines one part best at a time. The normal eye when it has normal vision is seeing an illusion and sees one letter best of a line or one part of one letter best at a time.

The eyes shift from part to part on the letter, seeing one small part at a time best, clearest in the center of the visual field. The center of the visual field moves with the eyes from part to part. The eyes can shift so quickly, that the whole letter, all parts appear equally clear at the same moment. The center of the visual field is clearest due to the fact that the macula and fovea centralis in the center of the retina produces the clearest vision in the center of the visual field. The part of the object the eyes are looking at is placed in the center, clearest area of the visual field. Moving the head/face, body with the eyes, same direction, improves central fixation and shifting.

We do not see illusions, they are imagined. Central fixation is a truth to which there are no exceptions and yet it is all imagination. The more perfect the imagination, the more perfect the sight, the more perfect is central fixation.

It is interesting to realize that the truth about vision in all its manifestations, does not obey the laws of physiology, the laws of optics, the laws of mathematics, and to try to explain in some plausible way, why or how all these things are so, is a waste of time, because I do not believe anybody can explain the various manifestations of the imagination.

Most people have an imagination that is good enough to cure them if they would only use it. What we see is only what we think we see or what we imagine we see. When we imagine correctly we see correctly, when we imagine imperfectly we see imperfect. People with imperfect sight have difficulty in imagining that they see perfectly at twenty feet the same letter that they do at one foot or less.

It can be demonstrated that when one remembers a letter perfectly one cannot at the same time remember some other letter imperfectly. The same is true of the imagination and of the vision. This fact is of the greatest importance in the treatment of imperfect sight without glasses. **If one can remember perfectly a mental picture of some letter at all times, in all places, the imagination and vision for all letters regarded are also perfect.**

One can improve the memory by alternately remembering a letter with the eyes closed for part of a minute or longer and then opening the eyes and remembering the same letter for a fraction of a second. Unfortunately it is true that many people with imperfect sight are unable to remember or imagine mental pictures perfectly. The treatment of these cases is complicated.

One patient when he looked at a white pillow saw it without any difficulty. He thought he saw it all at once. When he closed his eyes he could not remember a mental picture of the pillow.

With his eyes open I called his attention to the fact that he did not see the whole pillow equally white at the same time but that his eyes shifted from one corner that he saw best to another corner or to another part of the pillow and that he successively imagined one small part of the pillow best. With his eyes open he could not see two corners of the pillow best at the same time. He had to see it by central fixation, one part best, in order to see it perfectly. I suggested that when he closed his eyes he remember the pillow in the same way, one corner at a time or one small area best at a time.

He immediately for the first time in his life obtained a mental picture of the pillow. Afterwards he became able to remember or imagine a mental picture of the pillow with his eyes closed by practicing the same methods. He became able to imagine mental pictures of one letter at a time. Always he found that he could not remember the whole letter at once. The strain was evident and made it impossible. By alternately remembering a mental picture of a letter with his eyes closed and remembering the same picture with his eyes open for a short fraction of a second he became able to remember the mental picture of a letter when looking at a blank wall where there was nothing to see, just as well as he could with his eyes closed.

It required many hours of practice before he could remember the letter perfectly when looking anywhere near the Snellen test card, because he could not remember one letter perfectly and imagine one letter on the Snellen test card imperfectly without losing the mental picture. In other words he could not imagine one thing perfectly and something else imperfectly at the same time.

After a patient has become able under favorable conditions to imagine mental pictures as well with the eyes open as with the eyes closed, his cure can be obtained in a reasonable length of time. One patient, for example, could not see the largest letter on the Snellen test card at more than three feet but by practicing the memory of the mental picture of a letter, alternately with his eyes closed and with his eyes open, he was permanently cured in a few weeks.

In the beginning even with the strong glasses the vision that he obtained was one-tenth of the normal, but with the help of the mental pictures he became able to read without glasses at twenty feet a line marked ten on the Snellen test card. School children who have never worn glasses, under twelve years of age, can easily be cured by their teachers in two weeks or less.

It is very important that all patients who desire to be cured of imperfect sight should discard their glasses and never put them on again for any emergencies. It is not well to use opera glasses. Going without glasses has at least one benefit: it acts as an incentive to the patient to practice the right methods in order to obtain all the sight that seems possible.

All magnifying glass for distant or close: magnifying glass lens for reading, seeing small objects, microscopes, binoculars (this

includes close and distant eyeglass lenses), cause vision impairment.

## PREVENTION OF MYOPIA IN SCHOOL CHILDREN

About fifteen years ago I introduced my method for the prevention of myopia in school children in a number of the schools in the City of New York. In one year I studied the records of twenty thousand children who had been tested before and after the treatment. To prove a negative proposition, to prove that something does not occur because something else is done, is a difficult or impossible proposition. When I recommended my treatment for the school children I claimed that every child who used the method properly would see better and that no matter how poor the sight might be or how long the sight had been imperfect the vision would be improved always.

I made the statement that if there were one exception my method was only a working hypothesis at best or a theory, and that I was wrong about everything I said. Since all the children who used the method had their sight improved it is evident that imperfect sight from myopia was prevented in those children at that time.

I have published from time to time reports on results of my method for the prevention of myopia in school children. These reports are on file in the New York Academy of Medicine and can be consulted by anybody.

In 1912 I read a paper on this subject before the New York County Medical Association in which I made the statement that every child with normal eyes and normal sight who strains to see at the distance becomes temporarily or more continuously near-sighted. There are no exceptions.

If one competent ophthalmologist can prove that I am wrong about one case, I am wrong about all the statements I have made about myopia. This experiment can be performed in the doctor's office or at his clinic and the facts determined with the aid of a retinoscope, an instrument used for measuring the amount of near-sightedness which may be present in the eye.

There were present at this meeting a large number of prominent eye doctors of the City of New York. They knew that I was going to make this statement and issue this challenge because I sent a copy of my paper to these gentlemen two weeks before I read it. It would have been very easy for any of them to have tested the matter and determined whether I was right or wrong, but when the Chairman of the Society called on them to discuss my paper they declined to say anything about it or to publicly deny it.

I have the records of many persons who threw away their glasses and now have perfect sight with normal eyes.

They did it.  
Everybody can do it.  
YOU can do it.

## The Use Of The Sun Glass

In using the sun glass, it is well to accustom the eyes of the patient to the strong light by having him sit in the sun with his eyes closed, and at the same time he should slowly move his head from side to side, in order to avoid discomfort from the heat. Enough light shines through the eyelid to cause some people a great deal of discomfort at first, but after a few hours' exposure in this way, they become able to gradually open their eyes to some extent without squeezing the lids. When this stage is reached, one can focus, with the aid of the sun glass, the light on the closed eyelids, which at first is very disagreeable. When the patient becomes able to open the eyes, he is directed to look as far down as possible, and in this way the pupil is protected by the lower lid. Then by gently lifting the upper lid, only the white part of the eye is exposed, while the sun's rays strike directly upon this part of the eyeball. The sun glass may then be used on the white part of the eye. **Care should be taken to move the glass from side to side quickly. The length of time devoted to focusing the light on the white part of the eye is never longer than a few seconds.** After such a treatment the patient almost immediately becomes able to open his eyes widely in the light. Plain sunning without the sun glass is equally beneficial in most cases. Also, shining direct sunlight (no sun glass) onto the sclera, white part of the eye is healthy. Sun glass is used only by a experienced ophthalmologist and only in a case of near or complete blindness when plain sunning without the glass does not improve the sight.

Sunning - Face the sun, eyes closed and move the head slowly side to side.

Sunglass - Eyes closed. Head still. Sunglass with sunlight shining through the glass is moved quickly, 1-2 seconds on the eyelids.

Sunglass with eyes open - Head still. Eyes looking down, pupil under eyelid. Sunglass moves the sunlight quickly, 1-2 seconds on the sclera, upper white area of the eye.

Sunglass is used only in cases of blindness, by an experienced ophthalmologist, only when other methods have not helped restore the vision.

Sunlight shining on the sclera, white part of the eye. Person looks down, eyes pupil under the lower eyelid. Upper lid is pulled up to expose the sclera to the sunlight.

AUGUST, 1929

**Comparisons**

In practicing with the Snellen test card, when the vision is imperfect, the blackness of the letters is modified and the white spaces inside the letters are also modified. By comparing the blackness of the large letters with the blackness of the smaller ones it can be demonstrated that the larger letters are imperfectly seen.

When one notes the whiteness in the center of a large letter, seen indistinctly, it is usually possible to compare the whiteness seen with the remembered whiteness of something else. By alternately comparing the whiteness in the center of a letter with the memory of a better white, as the snow on the top of a mountain, the whiteness of the letter usually improves. In the same way, comparing the shade of black of a letter with the memory of a darker shade of black of some other object may be also a benefit to the black.

Most persons with myopia are able to read fine print at a near point quite perfectly. They see the blackness and whiteness of the letters much better than they are able to see the blackness of the larger letters on the Snellen test card at 15 or 20 feet. Alternately reading the fine print and regarding the Snellen test card, comparing the black and white of the small letters with the black and white of the large letters, is often times very beneficial. Some cases of myopia have been cured very promptly by this method.

All persons with imperfect sight for reading are benefited by comparing the whiteness of the spaces between the lines with the memory of objects which are whiter. Many persons can remember white snow with the eyes closed whiter than the spaces between the lines. By alternately closing the eyes for a minute or longer, remembering white snow, white starch, white paint, a white cloud in the sky with the sun shining on it, and flashing the white spaces without trying to read, many persons have materially improved their sight and been cured.

**School Children**

By W. H. BATES, M.D.

**Imperfect sight** is found in the eyes of most school children of the United States, Canada, France, and other countries. In Germany a great deal has been done to lessen this evil among school children and it is well known that the statistics of imperfect sight in school children in Germany have proved that the numerous methods recommended for the prevention or cure of imperfect sight have been failures. It is estimated that in the city of New York, one tenth or more of the children are wearing glasses. All attempts to benefit the eyes of school children so that they will not need glasses have been suppressed by the Board of Education and the Board of Health. Many principals of large schools have encouraged to the best of their ability the work that can be done to cure or prevent imperfect sight in school children. It is difficult to understand why there should be so much opposition to this work.

In 1912 all school teachers were encouraged in some of the larger schools to recommend and practice any methods which promised prevention or cure. One of the opponents of the prevention of imperfect sight in school children made the statement that it is impossible to cure a negative proposition and therefore a negative proposition cannot be prevented. A positive proposition is one in which a cure can be obtained by treatment. When the methods employed do not cure imperfect sight without glasses, one cannot expect the same methods to prevent imperfect sight. A positive proposition suggests methods that cure; a negative proposition does not suggest successful treatment and does not prevent imperfect sight. Measures that cure also prevent; methods that do not cure cannot be expected to prevent.

In some cities it was believed by many that the cause of imperfect sight in school children was the use of small print in the text books. When schools were permitted to use only large print for the children, eye strain, headaches and other troubles became more numerous than when small print was employed; repeated trials of books in which large print was used always failed to prevent discomfort. Just as many children wore glasses after the use of text books with large print as when the books were printed in small print. Even the school authorities and the Board of Health were finally convinced that large print was more injurious to the eyes of school children than was the small print which had previously been used continuously. Evidently, the cause of imperfect sight in school children was not connected in any way with the size of print used in text books.

It has been generally believed also that the imperfect light of school rooms is the cause of imperfect sight in school children. In some cases there seemed to be too much light, while in other cases it was believed that there was not enough light. I have studied the connection of the amount of light to the cause of imperfect sight. After many years of observation, I became convinced that the amount of light has nothing whatever to do with the cause of myopia, hypermetropia, astigmatism, or other cases of imperfect sight in school children. Many children with high degrees of myopia and other causes of imperfect sight have been permanently cured by **practicing the reading of microscopic type**, with changing powers of illumination. It is an error to claim that light has anything to do with the production of imperfect sight. Children with progressive myopia have been benefited or cured by eye education when a poor light or a bright light was used.

Fluorescent lights impair the clarity of vision, health of the eyes.

In Germany and in other parts of Europe, as well as in this country, the problem of the cause of imperfect sight in school children has received a great deal of attention. For example, in the year 1882, the minister of public education in France convoked a committee which investigated very thoroughly the light in school rooms. The committee dwelt especially upon the point that as the most essential light was that which shone directly from the sky upon the scholars, every scholar should be in a position to see a piece of the sky corresponding in size to a window space of at least 30 centimeters (about 12 inches) long, measured from the upper edge of the glass, of the upper window.

There is a large library of books describing the necessity of the proper amount of light, as measured with scientific instruments, each instrument being different in some particular from every other instrument for measuring the light. These studies and the injurious or the beneficial effects of light will now have to be modified, as I have found that the light has nothing to do with the cause of imperfect sight and that any measures adopted to change, lessen, or increase the light are usually a waste of time and effort. Scientists now know that full spectrum sunlight, entering the room through open windows, skylights, (and if necessary: full spectrum

non fluorescent light) improves the health, function of the eyes, brain, body and clarity of vision.

A study had been made in some schools of the desks where the children do their work. Here again much time was spent uselessly in publishing rules for the measurement of the height of the desks.

Dr. Cohn has done an enormous amount of work to determine the cause, prevention, or cure of imperfect sight in school children. He recommended what was considered to be the best form of lighting in schools and also devoted a great deal of time to desks and seats. He advised that the seats and desks be so arranged so that they would give the children the most comfort. He believed that he had made a valuable discovery toward prevention of imperfect sight when he recommended an apparatus which prevented school children from leaning far forward when they were studying or writing.

The apparatus was successful up to a certain point; it prevented the children from leaning far forward; he did not claim that his methods were a cure for all cases. After his method for the prevention of imperfect sight in school children had been in use for some time, the vision of the children was tested. Much to the surprise of the parents of the children, the vision was not benefited. A friend asked Dr. Cohn for his statistics on children who were benefited; he said that no children were benefited and that the method was a failure. He was then asked why he continued to use the method when he knew that the children were not benefited. Cohn's answer was that he did not know what else to do. A number of prominent ophthalmologists were disappointed when he admitted that his system was of no practical use. Good posture improves the vision but complete freedom of movement, relaxed body, neck, head, eyes must be allowed.

**I have proved that any effort or strain to improve the vision always lowers the vision. Straining the eyes to see at long distances always produces near-sightedness. When efforts were made to see at the near point continuously, the eyes became far-sighted. It can be demonstrated that the normal eye with normal sight becomes imperfect by a strain to see. When the eyes are relaxed the vision always becomes normal. One of the best methods for children to practice in order to produce relaxation is that in which the body is swayed from side to side. This prevents strain, because the eyes are kept in motion and the stare is avoided. When the eyes stare, an effort has to be made to prevent the eyes from moving.**

It is a rest to the eye to shift from one point to another point. When done easily, without effort, the eyes are rested, the vision improves, and the stare is prevented. Swinging was first used to rest the eyes and it was not expected that the movement of the eyes slowly, continuously, would be followed by any other benefits. It was demonstrated, however, that all children who practiced the method, besides relaxing their eyes also obtained relaxation in all parts of their body.

It is a fact—a truth—that rest improves the sight and relieves or cures many diseases of the eyes. Those children who do not practice the sway correctly are not benefited. The most common mistake that is made is to turn the head to one side and turn the eyes in the opposite direction while swaying. In many cases the strain is so terrific that it is followed by much pain or discomfort, and imperfect sight.

I have found that a great many children strain while they are asleep; this I have discovered by the use of the ophthalmoscope, without necessarily awakening the child. Those children who strain during sleep are often very nervous while awake and suffer from headaches and pain in the eyes and other parts of the body. **Practicing the swing properly just before retiring at night fifty to one hundred times is beneficial.** Some children will palm until they go to sleep. This produces relaxation which may last through the night and bring relief. This method of prevention may be practiced by young children at the age of four as well as by older children.

The writer wishes to recommend a method for the cure or prevention of imperfect sight in school children which has been used successfully. A Snellen test card is placed permanently on the wall of a class room in a place where it can be read at all times by the children. All the children's eyes were tested at ten feet each day, first with both eyes together and then with each eye separately. All the teachers who practiced the methods reported that every child who used the method regularly was benefited to a greater or lesser degree. Not only was the sight improved but also headaches, pains, and other nervous symptoms were relieved. One of the greatest benefits of the method was that it cured retardation. The mentality of children who had been backward in their studies was improved so that they were able to keep up with the work along with the other children.

Long Swing

Body, head, eyes move together, at the same time, in the same direction.

Sway/rock left and right.

were able to keep up with the work along with the other children.

Incorrect - Swaying left, eyes move in the opposite direction to the right

Correct - Swaying left, eyes move with the head, body in the same direction.

Long Swing - Swinging and turn left and right eyes, head/face, body move together, at the same time, in the same direction.

Person is turning to the left (diagrams are of a person facing the reader) and the eyes move with the head, body in the same direction to the left.

## School Children

By EMILY A. BATES

THE number of school children who were successfully treated during the past year by Dr. Bates, Miss Hayes, our assistant, and myself, far exceeds that of the year before. Our records show that the Bates method is becoming better known all over the world.

Children with imperfect sight who come to us for treatment and who have never worn glasses, are very easily cured. Some need only one treatment while others need one or two weeks of daily treatment before the sight is brought back to normal. Some cases of high myopia or hypermetropia need personal supervision for even a longer time, especially when eyeglasses have been worn. During the last year I have had quite a number of school children under my care and up to date not one of them has failed me. According to my records and reports by letter, every one of them has had permanent benefit.

June and Donald are brother and sister. A former patient of Dr. Bates met their mother and told her what Dr. Bates had done for her and for her children. Then she came to us. They came on June 14, 1929, and each of them was examined by Dr. Bates. Donald is eleven years old and a manly little chap. He had mixed astigmatism with myopia. Two years ago he put on glasses for the first time, and from the time he put them on, his mother

Incorrect Vision Habit, incorrect posture.  
Eyes up looking over top of the eyeglasses, head bent down. Neck tension, eye muscles tense, dysfunction, eye strain, increased blur, astigmatism, cataracts and other eye problems.

Looking down under the eyeglasses with the head tilted up and use of bifocals also causes this vision impairment.

noticed that he **acquired the habit of lowering his head to look at anything he wanted to see at close range. While lowering his head, his eyes were looking upward. This caused constant strain.** The mother noticed that Donald did not do this when he removed his glasses at night. She also noticed that he was less nervous without his glasses than he was while wearing them. From time to time during the two years in which he wore his glasses, he was taken to different eye specialists, to find out if he was wearing the wrong glasses, which was thought to be the reason why he held his head in an unnatural position. The doctors who examined him told her that he would outgrow this habit in time and that the glasses were quite right for him.

Doctor is wrong! The glasses caused the patient to develop this incorrect vision habit which causes more vision impairment, eye muscle tension, dysfunction, neck tension, pain... See Thomas Quackenbush's book, "Relearning to See" for description of Incorrect Vision Habits that cause unclear vision and Correct Vision habits (normal eye function) that produce clear vision, healthy eyes.

The vision of both eyes was the same, 15/30 minus, which meant that Donald could only read some of the letters of the 30 line of the test card. Even with the largest letter of the card which is seen by the normal eye at 200 feet, he strained to see. After his eyes were tested with the test card and Dr. Bates had examined him, we proceeded in the usual way of testing his eyes with the various test cards at ten feet. He was eager to see what could really be done for him so that he could get rid of his horrid glasses. I asked him if he enjoyed football, swimming, horseback riding, and baseball. He said there was no need in going any further about what kind of sports he liked most. He said he liked them all, but that his glasses hindered him from participating in such fun for fear of having an accident, which would cause him to lose his sight. When a boy talks like that, it doesn't take very long for him to respond to the treatment and to carry out the instructions necessary to restore his sight to the normal.

I explained to Donald how mental pictures help when the eyes are closed, and that if he could remember something perfectly, while he was resting his eyes, such as a letter of the test card, a rainbow with its many colors, a beautiful sunset, or his cravat, with stripes of colors, which could be remembered while his eyes were closed, or any object which is pleasant to the eyesight, he would no doubt be able to read the test card better when he again opened his eyes.

He followed my suggestion carefully in looking at a letter of the test card then closing his eyes and drawing the outline with his finger while his eyes were closed. I asked him if he could remember the shade of the letter. The letter was black and the background was white. He said that he could remember the letter was a perfect black by first imagining that the background was as white as snow or as white as a white cloud. **He said he could feel the movement of his eyes as he outlined the letter with his finger.** Donald enjoyed the fun, as he called it, outlining letters while his eyes were closed and then occasionally looking at the card to read a few more letters.

The brain works with the eyes; when shifting on a object in the mind, imagination, drawing a object in the air, the brain continues to activate eye movement.

Draw a letter in the palm of your hand with the other hands finger, eyes closed and feel the eyes move as the finger moves on the hand and the mind visualizes the letter being drawn.

Helen Keller used this method to learn how to speak, communicate.

His sister, who was sitting outside of the room but could hear everything that was said, was a little doubtful about what could be done for her eyes. The mother was in the room watching everything that was going on and taking notes so that she would know how to take care of Donald's treatment at home. Patiently, Donald worked with me, resting his eyes by closing them frequently when I told him to, and outlining the last letter he saw on the test card each time he rested. As the sun was not shining in the room where he was being treated, a thermo-lite was used, which the seemed to like very much. The light and heat helped in the improvement of his vision and also helped him to look at the card, without lowering his head.

As his mother watched the steady improvement in his sight, she could not suppress her enthusiasm and gratitude. Occasionally, she would remark to her boy, "Think of it, Donald, you will not need glasses ever again." Gradually, I placed the test card farther and farther away and in an hour's time, he read 10/15 with each eye. I placed him comfortably in a chair, telling him not to open his eyes, but to take the light treatment until he felt uncomfortable, and then to shut off the light and still keep his eyes closed while I treated his sister, June.

June is nine years of age and had worn glasses for a year or more. She had trouble in keeping her eyes open normally without her glasses and closed them almost entirely in order to see. She preferred to do this rather than to wear her glasses. She also had myopia, about the same degree as her brother. When I placed her before the test card, ten feet away, she strained to see the letters and did not blink as I pointed to the largest letters of the test card. She could read the first three lines by squeezing her eyes together, but the letters looked blurred to her. By closing her eyes often, following the treatment I gave her brother, imagining the white background of the card whiter than it really was and imagining the black letters blacker, outlining letters with her forefinger as she mentioned them, her vision with each eye improved to 10/30. It took about an hour to improve her vision to 10/10, but gradually as she read one line after another, alternately closing her eyes to rest them and receiving the thermolite treatment frequently at short intervals, she became able to read with her eyes open in a normal way. I told her to sit with her eyes closed for a while and to remember familiar objects as I had advised Donald to do.

Then I returned to Donald to give him more help. I placed the test card thirteen feet away and by receiving a little light treatment, at intervals, with the light about ten feet away from him so that the rays was not too strong for his eyes or the heat too great, he became able to read the smallest letters of the test card without any strain or discomfort. The long swing was added to the latter part of his treatment, swaying and looking at a blank wall where there was nothing to see and then to the test card, reading one letter at a time and then swaying again to the blank wall.

Then June followed her brother in the treatment, doing just as well as he did with the reading of the test card letters at 13 feet. This is more than the normal distance.

Both children expressed their gratitude to me for the help that had been given them and then they insisted that Dr. Bates be called away from his work to come to them for his share of praise. They wanted to shake hands with the great man who could do so much good for school children.

I was very tired that morning and did not feel physically fit to look after the work that had to be done. After Donald and his sister June had spent more than two hours with me, I was relieved of all fatigue and discomfort for the rest of the day. I had a good reason to be happy and to feel that something good had been done; because I had helped two children obtain normal sight in one treatment. After the children had left, their mother promised to write to us for further help, if further help was necessary. She was not to communicate with us unnecessarily, if the children retained their normal vision. Up to date, we have not heard from the

+Shift, then trace on/along a letter T on the test card.

+Then, close the eyes and imagine seeing the T and trace, draw on the T in the mind and, at the same time: draw the letter T in the air with the finger.

Improves memory, imagination, eye movement, visualization of a clear mental picture of the letter.

+Eyes open, repeat and experience clear vision.

Persons blind from birth or at an early age use this and similar methods (feeling objects, symbols of objects...) to gain mental pictures of objects and this helps to restore their vision, the brain's function with the eyes when the vision returns.

mother.

Paul was another boy who came for treatment about the same time. His father telephoned before sending his son, telling me that the school authorities had insisted very strongly that he get glasses for Paul, but the father refused to submit to such a thing, until he was sure that nothing else could be done. Paul had never worn glasses and when they were suggested to him, if Dr. Bates could not help him, he wept bitter tears and at times was disobedient, which sometimes called for punishment.

Paul came with a written statement from his mother, saying that at the age of five years, he was taken ill with measles and after that sties appeared at intervals, causing an almost constant inflammation of the eyelids. Because Paul had played with a child who was supposed to have an incurable eye trouble, Paul's mother feared that he had acquired this incurable disease also. His eyelids were itchy most of the time and at the advice of an eye doctor a solution of boric acid was used and a medicine called "mecca" was also applied. Paul found some relief from the use of these applications, but the sties appeared just the same and he noticed that the letters on the blackboard at school became less distinct at such times.

In 1928 he had scarlet fever, and pink eye began three months previous to his visit to me. Paul's vision with each eye was 10/10 but he strained to see as he read the smaller letters of the test card. The sun was shining through the windows in the room where I was treating him. I placed him in the sun with his eyes closed and used the sun glass rapidly on the edge of his eyelids as well as on the upper and lower lids. This was about midday, and the sun was rather hot so I had to use the glass very rapidly in order to avoid any discomfort or burning of the lids. His elder brother who came with him remarked how well the eyelids looked after the sun treatment. This was accomplished in less than an hour's time.

After the sun treatment, I placed the test card at ten feet. He read the smallest letters without any effort or strain. Again I placed him in the sun and taught his elder brother how to use the sun glass while I was occupied with something else. We had to keep Paul busy while he was resting this way, because he was restless and being a perfectly normal healthy boy did not like being quiet. He told me a funny tale and then in turn I told him one and in this way we passed the time away. Finally after another half hour of sun treatment, Paul read all the tests cards with different letters at fifteen feet from his eyes without any trouble whatever.

The irritation of the eyelids had disappeared and the itching had stopped, but Paul was told that this might be only a temporary relief and that he would have to take a good deal of sun treatment before he was finally rid of his trouble. He promised to take all the sun treatment he could possibly get by placing himself in the sun, and raising his head so that the sun could shine on his closed eyelids. He was given a test card to practice with daily and to use to show his mother how far away he could read it while blinking and swaying his body from side to side to avoid the stare.

Paul and his brother promised to notify Dr. Bates if he needed further help, or if he had any further discomfort with his eyes. Two weeks later, his elder brother came to report that apparently Paul was cured in one treatment because no further complaints came from the school about his having to wear glasses nor did the irritation of the eyelids reappear. I am sure that Paul himself takes time enough for the sun treatment whenever there is sun, because he promised me faithfully that he would do so without troubling any member of his family.

## Case Reports—School Children

By KATHERINE HAYES

Since it has been my privilege to assist Mrs. Bates in clinic work, I have come in contact with a number of interesting cases, especially among children of school age. I have found that children as a rule respond much more readily to treatment than adults and I believe the reason is because they have a natural aversion to the wearing of glasses and are willing to learn how to improve their vision without them. I think this is especially true of children from ten to fourteen years of age who have some definite reason for wanting to discard their glasses.

About six months ago, a little girl came to the clinic for treatment. I noticed as she came into the room with her mother that she was unusually pretty, but I also noticed that she kept looking down and did not raise her eyes once. While she waited for her turn, her grown up manner was most amusing, not only to me, but to the patients in the room. Every few moments she would take out a hand mirror from her little purse, survey herself critically and then place the mirror back in her purse, quite unaware of the attention she was causing and of the embarrassment of her mother.

When this girl's turn came for treatment, her mother gave me an account of her case. She was eleven years of age and had been wearing glasses off and on for **squint** for five years. When she was six she had an attack of **whooping cough** which caused her left eye to turn in. The vision in that eye was also impaired. They had been to several eye doctors, most of whom had advised an operation, but her mother was unwilling to have the child submit to this. After her mother had finished, the little girl came over to me and said in a confidential tone, without raising her eyes: "You know, people say that I would be quite a little beauty if it weren't for my cross eye. I hate glasses because they make me homely and I only wear them once in a while. Someday I want to be an actress on the stage or in the movies and I know they won't take me if I am cross-eyed. Can my eye ever be made straight again?" I told her I thought it could, if she would do what she was instructed to do at home and come regularly to the clinic.

I tested her sight and found that in the right eye it was 15/10 or better than normal, while in the left eye it was 15/50. I showed her how to **palms**, which she did for fifteen minutes. I then told her to remove her hands from her eyes. For a moment, her eye was straight. I tested her vision again and found that by having her **sway and blink as she read the card**, her vision improved to 15/30. I told her to practice palming every day as many times as possible for five minutes at a time, to practice the **long swing 100 times morning and night**, and to remember to **blink her eyes frequently**.

When she came again, two weeks later, her vision was still 15/30, which indicated that she had been faithful in her practice work. I also noticed that her eye was not quite as crossed as it had been. She came regularly for about four months and the last time she came her vision in the left eye had improved to normal and her eye was perfectly straight. Little Elsie was very happy. I told her that even though her vision was normal and her eye straight she should remember to **rest her eyes occasionally, in order to avoid any strain which might lower her vision and cause a return of the squint**. I have not seen or heard from her since, but I am sure that her vanity, if nothing else, will encourage her to take good care of her eyes.

About the same time a boy of thirteen came for treatment. He was wearing glasses which he had been using for three years. His dislike of glasses was not prompted by vanity as in little Elsie's case, but was because being a real boy, he liked all sorts of sports and could not engage in any of them because of his "old glasses" as he called them. "Gee," he said, "if I didn't have to wear those things, I'd be happy."

After testing his vision, I found that he had quite a high degree of myopia. His vision was 15/70 with both eyes. Palming seemed to make him restless, so I told him to just close his eyes and sit back comfortably in the chair. After twenty minutes, he was directed to stand up and look out the window, then to start swaying from side to side as he blinked his eyes. After practicing this for five

minutes, I again tested his vision, and found that it had improved to 15/40. I told him to leave his glasses off and gave him instructions to follow at home.

When he came again, his vision was not quite 15/50. He said that he had had a bad cold and was not able to practice. I gave him light treatment for about twenty minutes, after which his vision improved to 15/30 minus. I told him to get a great deal of sun treatment at home, letting the sun shine on his closed eyelids as he moved his head slowly from side to side. When he came again, his vision had improved to 15/20 minus. He continued to improve steadily and when he came the last time, which was about a month ago, his vision was normal in both eyes. Needless to say he was a happy boy, and incidentally, as he was leaving the office he said that he thought Dr. Bates was the most wonderful man in the whole world, with the exception of his own father.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

SEPTEMBER, 1929

### The Colon

While the colon is a valuable punctuation mark, it has a very unusual and better use in helping the memory, imagination, and sight. Medium sized or small letters at the distance are improved promptly by the proper use of the colon. While the eyes are closed or open, the top period should be imagined best while the lower period is more or less blurred and not seen so well. (Central Fixation) In a few moments it is well to shift and imagine the lower period best while the upper period is imagined not so well. Common sense makes it evident that one period cannot be imagined best unless there is some other period or other object which is seen worse. The smallest colon that can be imagined is usually the one that is imagined more readily than a larger colon.

When palming, swinging, et cetera, cannot be practiced sufficiently well to obtain improvement in the eyesight, the memory or imagination of the small colon, one part best, can usually be practiced with benefit. To remember or imagine a colon perfectly requires constant shifting. When the colon is remembered or imagined perfectly, and this cannot be done by any effort or strain, the sight is always improved and the memory and imagination are also improved. It is interesting to note that the smaller the colon, the blacker and better can one remember, imagine, or see one period of it, with benefit to the sight. One may feel that the memory of a very small colon should be more difficult than the memory of a large one, but strange to say it can be demonstrated in most cases that the very small colon is remembered best. If the movement of the colon is absent, the sight is always imperfect. In other words, it requires a stare, strain, and effort to make the colon stop its apparent motion. Shift top, bottom, top, bottom on the two dots of the colon : and see the colon move in the opposite direction that the eyes shift to.

Look at, shift on one period at a time. Do this with the eyes open, then in the imagination with eyes closed, then with eyes open again.

The period the eyes are looking directly at is in the center of the visual field and is clearest. The other period is in the peripheral field and is less clear.

When the eyes shift to the period in the peripheral field, that period is now in the central field and is clearest and the other period is now in the peripheral field and is less clear. Shift back and forth on the periods. Practice on small and fine print colons.

## Retinitis Pigmentosa

By W. H. BATES, M.D.

There are many cases of imperfect sight which are congenital. That is, people are born with different diseases of the eye. Retinitis pigmentosa is usually congenital. The condition is easily recognized in most cases with the aid of the ophthalmoscope. In all cases, the retina is covered, more or less completely, with black areas. These black areas are about 1/30 of an inch in diameter. They are very irregular in size and shape. In severe cases of retinitis pigmentosa, the retina may be covered so thickly by these black specks that the retina cannot be seen.

Most cases give a history of poor sight from birth. At first, only a small number of black spots are visible, but after the child is twelve years of age or older, the number of these spots increases gradually. At the same time that these spots are increasing, there are serious changes taking place in the back part of the eye. The optic nerve becomes atrophied, but the atrophy does not increase sufficiently to produce complete blindness. The middle coat of the eyeball is inflamed and produces floating spots in the vitreous (one of the fluids in the back part of the eye).

All cases of retinitis pigmentosa acquire cataract before they are thirty years of age. There are exceptions to this rule, however. Some patients acquire retinitis pigmentosa after they are fifty years of age or older. One characteristic of retinitis pigmentosa is that the vision is always changing, sometimes for the better, sometimes for the worse. One very common symptom that is usually present is night blindness. **Treatment for the cure of the night blindness helps retinitis pigmentosa.** In some cases myopia is present and it is of a kind which is difficult to cure.

It is a prevailing belief that retinitis pigmentosa is incurable and that when it becomes manifest in its early stages, the condition goes on increasing and the blindness becomes more decided. Usually, the blindness does not become permanent. One case of retinitis pigmentosa with myopia was observed. The patient left town and was not seen again for more than six months. She then came into the office to report. Her first words were that her eyes were better.

A physician was calling on me at the same time, and he was asked: "Would you like to see a case of retinitis pigmentosa." He replied that he would.

Before the doctor used the ophthalmoscope, I examined the eye myself. I examined the right eye first and found that the nasal side of the retina was not diseased. There were no black pigment spots anywhere to be seen on the nasal side. Somewhat disturbed, I examined more carefully the temporal side of the retina and again I was disappointed because there were no black spots there. After a long and tedious search for the black spots, I had to confess to my friend that the **patient had recovered from the retinitis pigmentosa and accomplished it unconsciously without practicing relaxation methods.** The doctor could not resist looking at me incredulously. I am quite sure he thought I was not telling the truth. The atrophy of the optic nerve had also disappeared and with its disappearance circulation of the nerve was restored. The size and appearance of the nerve were normal. The patient became able to read 20/20 without any trouble. It is very interesting to observe in most cases of retinitis pigmentosa how much damage can be done to the retina, while the vision remains good.

Many physicians believe that **night blindness** cannot be cured. The majority of these cases in my practice have usually recovered and obtained not only normal vision, but they have become able to see better than the average. All patients who were suffering from chronic retinitis pigmentosa had **changes in the optic nerve** which were very characteristic. In the first place the **blood vessels were smaller than in the normal eye and the veins just as small if not smaller than the arteries** which emerged from the center of the optic nerve. In most cases the middle coat of the eyeball becomes inflamed and usually much black material is found in the vitreous. There are well marked changes which take place in the crystalline lens. The back part of the lens becomes cloudy and this cloudiness moves forward toward the center of the lens and clouds all parts of it so that the vision is lowered by the opacity of the lens as well as by the more serious changes which occur behind the lens.

A patient sixty years of age came to me for treatment. She said that the doctors told her that she had **retinitis pigmentosa** and that she could not be cured. Within the last few months her doctor had told her that a cataract had formed. Her vision was zero in the right eye, which had **cataract**. The vision of the left was about one third of the normal and was not improved by glasses. She had a well marked case of retinitis pigmentosa in which the retina of the left eye was apparently covered almost completely by the pigment spots. In some parts of the retina over an area of more than double the diameter of the optic nerve, the retina could not be seen.

The patient was very anxious to have me do what I could for her sight. She said that her husband was a business man and had occasion to travel all over the United States, Canada, and Europe. He frequently took her with him, and whenever they came to a large town where some prominent ophthalmologist had his office, she would consult him about her eyes.

I found that the back part of the crystalline lens was covered by a faint opacity which was sufficient to lessen her vision. The patient was **given a Snellen test card to practice with for the good eye**. In twenty-four hours the vision of the right eye had improved from no perception of light to the ability to read some of the large letters of the Snellen test card at five feet. Improvement in the vision of the left eye was manifest. The great improvement in so short a time in the vision of the right eye was unusual.

Treatment for retinitis pigmentosa and cataract

The treatment which improved the vision of this patient was **palming, swinging, and reading very fine print**. This patient gave evidence that retinitis pigmentosa is caused by a strain or an effort to see. The fact that retinitis pigmentosa in the eyes of this patient was so promptly relieved, benefited, or cured was evidence that **the disease was caused by strain**.

The clinical reports of other cases of retinitis pigmentosa confirm the fact that a strain or an effort to see produces retinitis pigmentosa. The efforts which are practiced by the patient can be demonstrated in every case. When the patient makes an effort to improve the vision, it can be demonstrated in every case that the cause of the eye trouble is always due to this effort and the **cure of the disease is always obtained by relaxation methods**.

I have found that among the methods of relaxation which secure the best results are the **memory or the imagination of perfect sight**. If the memory or the imagination is imperfect, the disease is not completely relieved or benefited. When one letter of the Snellen test card is seen perfectly, it can be remembered or imagined perfectly. There is no procedure which yields better results in the cure of this eye trouble than the memory of part of a letter, which the patient can demonstrate. It is very interesting to observe that in these cases the **memory and imagination are capable of bringing about the absorption or the disappearance of organic conditions**. This makes it possible for this treatment to accomplish results readily, quickly, when all other treatment is of no avail.

For example, a girl fifteen years of age had suffered from retinitis pigmentosa from birth. The disease was rapidly progressing and it did not seem that any relief would be obtained by any form of treatment; the patient was simultaneously suffering from progressive myopia. **Relaxation treatment**, the correct use of her **memory, and imagination** improved the progressive myopia and much to the delight of the patient, the retinitis pigmentosa improved at the same time and continued to improve until all traces of the disease were absent and she was permanently cured.

It seems to be one of the peculiarities of the disease that it is variable. Oftentimes it gets better for a short time when all of a sudden, overnight perhaps, the disease will return with all its accustomed forms of **black pigment spots, atrophy of the optic nerve, diminished circulation, and incipient cataract**.

Improved circulation in the eyes cures many vision/eye problems/diseases; Relaxation of mind, body, eyes, eye muscles, neck, eye movement/shifting, central fixation improves circulation in the body, brain, eyes.

Retinitis pigmentosa has been observed in cases of glaucoma, chronic cases which progressed with more or less rapidity until almost total blindness was observed. In other cases, different parts of the choroid would be destroyed, and there would be loss of vision in these areas.

The vision of children ten years of age, suffering from this disease, has been remarkably improved by **swinging the child in a circular direction several times daily repeated for many weeks**. This promotes **relaxation**. It is a mistake to dispose of **cradles, rocking chairs, and other methods of promoting the swing**. The long swing, (described several times in this magazine) is a very efficient method of obtaining relaxation. Many people object that children have not sufficient intelligence to practice the swing successfully. On the contrary children ten years of age or under can practice the long swing as successfully as many adults. It is a treatment that the patient enjoys to a decided extent. Games of all kinds should also be encouraged. It is well to **protect the child from adults and others who make the child nervous**. Nervousness always causes strain. **Laughter and good time are relaxing**. The kindergarten is a good place for all children at an early age, because relaxation methods of the best kind are taught there.

Before closing, reference should be made to a **girl fourteen years of age who cured herself of retinitis pigmentosa by playing games and engaging in sports that she enjoyed**. In the summer time she enjoyed swimming and diving from very great heights; in the winter time she practiced skating, devoting long periods of time to this sport. Besides the relaxation methods which I have described, it is worth the trouble to teach children who have so-called incurable diseases how to **enjoy themselves for long periods of time both winter and summer**. Their **eyes as well as their bodies are kept in motion while playing games or engaging in sports which relieve the stare and strain that cause imperfect sight**. It is so much more efficient and better than drugs.

#### The Swing

Swing the child around by the hands clockwise, counter-clockwise, clockwise. Child looks up into parents eyes and also sees oppositional movement of objects in the visual field moving by in the opposite direction the body is spinning toward. Improves clarity of vision, gets the eyes relaxed, moving normal, straightens crossed, wandering eyes, activates, integrates left and right brain hemispheres, relaxes body, mind, eyes in a active, dynamic, fun state of mind.

## Discarding Glasses Not Injurious

By EMILY A. BATES

THE most difficult thing for a patient to do is to discard glasses immediately. When a patient comes to us, recommended by his physician or oculist, we have no difficulty in this respect, even though he has worn glasses for many years. But when a patient comes for treatment at the suggestion of a friend or someone who has been benefited by the Bates method, there is sometimes a doubt in the patient's mind as to whether it is a mistake or injurious for him to stop wearing his glasses immediately, after having worn them for a long time.

Nineteen years ago I came to Dr. Bates as a patient. **Headaches, nausea, and continuous pain in the back of my neck** made me irritable and nervous, and sometimes I was not a very agreeable person to have about. A neighbor of my little mother first told me about Dr. Bates and how he had cured her five children of imperfect sight and other ailments.

I felt quite comfortable at times with the glasses I wore and because they helped me to see better I wore them almost constantly. As I explained in a previous article, I had worn glasses a little more than thirteen years, and during that time I had them changed three times. The last glasses I wore did not help me when I first put them on. The oculist informed me that I would have to wear them for a few weeks until I became accustomed to them. They were much stronger glasses than those I had worn previously and for that reason the oculist told me my eyes would adjust themselves to the glasses in time.

This must have been the case because after a while I got along nicely with them for a few hours every day but toward the end of almost every day the nausea and discomfort became a regular occurrence. When I visited Dr. Bates for the first time I did not know that the glasses I was wearing were the cause of my pain and discomfort. In fact I did not altogether believe that Dr. Bates was right in the diagnosis he had made of my case. I put my glasses away as he suggested, but the very next day I was ready to complain about my usual headache and other pain. However I did not have anything to complain about. But I neglected some of my daily duties about my home to practice what the doctor told me to do.

I soon found out that blinking often made me feel easier—that things about the house looked clearer to me when I blinked. I liked that, so I kept it up all day. Dr. Bates noticed during my treatment that I did not breathe regularly and advised me to do so. I made it a practice to blink as I inhaled and exhaled so one thing reminded me to do the other. As I looked into a mirror I noticed as I blinked that my eyes moved slightly, which gave me a sense of relaxation I did not have while wearing my glasses. Dr. Bates explained in his book and in other articles that he has written that when eyestrain is relieved, strain in all parts of the body is also relieved. Dr. Bates advised me to close my eyes to rest them, which always improved my vision for the test card.

The second day I wanted very much to put on my glasses again because I woke up that morning with a terrific headache. I was almost sure that Dr. Bates was wrong about the whole thing. I telephoned to him and argued the matter with him. I was much surprised to have him tell me that I might have strained my eyes during sleep. How absurd this seemed to me, but he was right about this and I will explain how I found it out for myself and how I relieved the strain by doing exactly as he advised me.

I placed my alarm clock on a chair beside my bed and set the alarm to ring two hours after I had fallen asleep. Being a light sleeper I did not wind up the alarm to ring more than a second or two. In this way I did not waken anyone else in my household. If I had a dream during those two hours of sleep, I had a pad and pencil near me to write down what I could remember of my dream. Some of our "Better Eyesight" readers will say that this was a waste of time and sleep and may even laugh at such a procedure during the night. Later on I was glad I did this because I was entirely cured of **nightmares**, which caused me many times to apologize for waking up members of my family with screams or causing other disturbances which were sometimes a great worry to those near me.

I practiced the **long swing for five minutes or longer every night and morning** in addition to other things that Dr. Bates advised me to do during the night.

Children are more ready to discard their glasses than are adults and for that reason there are more children cured without glasses than adults, and in a shorter time. Some patients who come to us for treatment have been wearing eye glasses that are very weak in power and yet they say they cannot possibly do without them. Doing without glasses a little longer each day is a good way to begin. If one has been wearing glasses for a long time, it is much easier for the patient to gradually do without them, if he is not under treatment for the removal of glasses.

A man, aged 57, who had astigmatism in both eyes, was afraid to leave off his glasses after the first treatment. He had worn glasses for thirty-six years, having had them changed several times during this period. At the age of 21, he paid his first visit to an oculist who told him that the compound **hypermetropic astigmatism** which he had would get worse if he did not wear his glasses steadily. He obeyed the oculist and in a year's time he had the glasses changed. The first few years he did not notice much discomfort while wearing the glasses, but later on if he did not remove the glasses occasionally and close his eyes to rest them, he would feel so tired that even at his work he would fall asleep.

He was examined by a good specialist who was recommended by his family physician, thinking that perhaps he might have had an attack of sleeping sickness. After chemical tests were made it was found that all the organs of his body were perfectly normal, and the doctor suggested that perhaps he might be wearing the wrong glasses. Then he became interested in the Bates method and came for treatment. I asked him to read the test card with his glasses on and he read 10/40. Without glasses he could not see anything on the test card clearly at ten feet, so I placed the cards at seven feet. At seven feet he could only read up to the 50 line letters of the test card.

He liked palming very much and kept his eyes closed for a considerable length of time while I was talking to his family physician, who came with the patient to see what could be done for him. I told my patient, while he was palming, that a good memory usually helped, but not to remember anything disagreeable while palming. He liked outdoor sports and was a good golf player, so I told him to imagine the golf ball as he sent it across the field and to imagine that it went into the cup. After he had rested his eyes in this way it was amusing to hear him tell us that he had had a good game of golf while his eyes were closed. Evidently this helped because his vision improved to 7/15, although all the letters on the 15 line were not entirely clear to him. When he strained to see some of the letters they became blurred and distorted and he read them incorrectly. After he had palmed his eyes again for a shorter period, he read all the letters of the 15 line clearly and without any hesitation whatever.

I gave him the Fundamental card to read and told him to hold it at the usual reading distance. He said all the print was blurred and he could not see anything but the word "Fundamentals" at the top of the card after he had closed his eyes for a few seconds. I told him to hold the Fundamental card in his left hand while in his right hand he held the small card with diamond type. I directed

him to look first at the white spaces of the small card in his right hand and then turn his head and look at the Fundamental card and not to try to read the letters. While he was doing this I told him to draw the Fundamental card a little farther away, about twelve inches from his eyes. By alternately closing his eyes to rest them, imagining the white spaces between the lines of type, and then looking at the beginning of each sentence, he read time to sentence number 6.

I told him to look directly at the print and see what happened. He immediately closed his eyes and said that the print blurred and that it made him uncomfortable. For almost an hour he practiced looking from the white spaces between the lines of fine print to the white spaces between the lines of larger print of the Fundamental card and before he left the office that day, he read all of the Fundamental card at six inches as well as at twelve inches. He telephoned a few days later and said that he felt no discomfort although he had discarded his glasses. There were times, however, when he did have a strong desire to put them on again. Advice by mail helped and in a year's time his vision became normal.

Having so little fear about removing his glasses after having worn them so many years was proof enough that it could be done. It requires will power and also confidence in the instructor or doctor who is teaching the patient to see without glasses.

It is a mistake for patients to discuss the treatment until they are cured, because friends have a certain amount of influence in the matter, either for right or wrong. While some patients are cured quickly, there are patients who do not do so well and keep practicing sometimes for a year or longer without obtaining a cure. This is because the method has not been practiced properly at home or the advice given by the doctor has not been carried out completely. Some patients need more supervision than others and for that reason it is best not to discuss the treatment with those who do not understand or who are skeptical about it. I have been assisting Dr. Bates long enough to know that glasses can be discarded permanently no matter how long they have been worn.

## Questions and Answers

Q—Is diabetic cataract curable?

Answer.—Diabetic cataract is curable when the general disease of diabetes can be relieved by treatment.

Q—After a serious illness several years ago my pupils became very large. Is there anything you can suggest that will help them to contract?

A—Dilated pupils are not usually symptoms of disease of the eye. The sun treatment is beneficial. Sit in the sun with the eyes closed, allowing the sun's rays to shine directly on the closed eyelids, moving the head a short distance from side to side to avoid discomfort from the heat. This should be practiced for a half hour, an hour, or longer.

Q—What causes my vision to become blurred upon sudden confusion or when I have a number of activities coming at once?

A—The fact that your vision becomes blurred at such times is proof of your eccentric fixation. Do not try to see or do several things at once. Practice central fixation, seeing the part regarded best and other parts not so clearly, all day long.

Q—My daughter, aged ten, is practicing your method for the cure of cross-eyes. Would it help to cover her good eye with a shield, which is easy for her and keeps the left eye straight for a certain period of time, besides making it work? It helped her so much when she wore glasses, that I thought it might help her without them in the same way.

A—It is first necessary to improve to normal the vision of both eyes, when used together. Then cover the good eye and practice improving the vision of the poor eye.

Q—When you suggest new methods do you mean to discontinue with the old?

A—Not necessarily. All the methods I recommend have relaxation for their object. It is for the patient to determine which treatment is most beneficial and to continue its practice faithfully. Some patients tire easily when one thing is done continuously. For this reason several methods are suggested in order to vary the practice.

Q—I am told that I am losing my "central vision." Is it possible to regain what I have already lost or to forestall the loss of the remainder?

A—Yes, it is possible by faithful practice of my methods.

Q—What causes my eyes to flash violet sparks and splashes?

A—This is caused by a mental strain.

Learn to **relax and improve your memory and imagination**. **Palming** should help you a great deal.

Staring, neck tension, incorrect posture, many hours with the head, neck bent down or pulled forward reading, typing without taking a break causes this symptom and unclear vision, dizziness.

Use correct posture, walk around, look to the distance to prevent tension in the neck, eyes, blur.

Q—It is very hard for me to think in terms of black and white. Is there some other method which is just as beneficial?

A—Yes, letting your mind drift from one pleasant memory to another will accomplish the same results.

Q—In case of illness where one is unable to practice with the Snellen test card or stand up, what method is used?

A—Blink frequently and shift your eyes constantly from one point to another. Turn your head slightly from side to side on the pillow or close your eyes and think of something pleasant, something that you can remember perfectly, and let your mind drift from one pleasant thought to another.

Q—What does "Seeing things moving all day long" mean?

A—Your head and eyes are moving all day long. Notice that stationary objects appear to move in the opposite direction to the movement of your head and eyes. When you walk around the room or on the street, observe that the floor or pavement appears to come toward you, while objects on either side of you appear to move in the opposite direction to the movement of your body.

OCTOBER, 1929

## The Memory Swing

The memory swing relieves strain and tension as do the long or the short swings which have been described at various times. It is done with the eyes closed while one imagines himself to be looking first over the right shoulder and then over the left shoulder, while the head is moved from side to side. The eyeballs may be seen through the closed eyelids to move from side to side in the same direction as the head is moved. When done properly, the memory swing is just as efficient as the swing which is practiced with the eyes open, whether it be short or long.

Feel the physical eyes move left and right when imagining moving left and right and when physically moving the head left and right. The eyes move in the same direction the mind imagines moving and the physical body, head moves. The brain works with the eyes.

This swing also relaxes, improves movement of the neck. Enjoy relaxation of the mind, eyes, head, neck, shoulders, body.

The memory swing can be shortened by remembering the swing of a small letter, a quarter of an inch or less, when the eyes are closed.

Eyes closed. Shift left and right on a small letter E in the imagination. See it move 1/4 inch or less in the opposite direction the eyes shift to.

The memory swing has given relief in many cases of imperfect sight from myopia, astigmatism, and inflammations of the outside of the eyeball as well as inflammations of the inside of the eyeball. It is much easier than the swing practiced with the eyes open and secures a greater amount of relaxation or rest than any other swing. It may be practiced incorrectly, just as any swing may be done wrong, and then no benefit will be obtained.

From Dr. Bates Better Eyesight Magazine.

Eyes closed. Imagine looking over the left and right shoulders. First do this without moving the head. Then, imagine looking left and right and move the head with the eyes. Move relaxed, easy - look left, then right, left, right... no hurry. Notice the eyes move under the closed eyelids when imagining looking left and right. The brain, memory, imagination, left and right hemispheres... control eye movement. This activity relaxes the eyes, eye muscles, brain, head, neck, activates easy eye movement/shifting and activates, integrates the left and right brain hemispheres.

## Mental Activity

By W. H. BATES, M.D.

IT IS a truth that activities of the mind under favorable conditions accomplish many things. As an example, let us consider the following case. A man, aged 30, employed in a distant city as a helper in a library, was treated about 15 years ago. He called to see me at about seven o'clock in the evening and remained with me for more than two hours. The patient was born with **cataracts in both eyes**. He also had **amblyopia from birth**. Some months previous to his visit, the cataract in both eyes had been removed. The vision of the right eye was very poor and not corrected by glasses. The vision of the left eye was worse than that of the right and also was not improved by glasses.

The treatment which was prescribed was to rest both eyes by closing them. His attention was also called to a known letter of the Snellen test card, a letter which he imagined better with his eyes closed than with his eyes open. When a known letter was regarded by central fixation, the vision improved. It did not take longer than half an hour to improve the right eye in this way, at first in flashes and then more continuously later.

At first he was able to flash the letters of the Snellen test card when he had momentary glimpses of the known letter very much improved. It did not take long before, much to my surprise, he was able to read all the letters on the lowest line at 10 feet. The vision of the left eye improved much more slowly, but after continual practice the vision of this eye became normal.

The eye which obtains improved sight by the aid of the memory and imagination very soon obtains improved vision for all the letters. It was demonstrated in this case and in others that **the memory and the imagination of a known letter is a cure for myopia, hypermetropia, astigmatism, cataract, glaucoma, atrophy of the optic nerve, and other diseases of the eye.**

With the aid of the retinoscope it has been demonstrated that the memory and the imagination are capable of improving the vision of these cases of refraction until the functional element is relieved. It is interesting to observe that these patients become able to see as well without glasses as they had previously seen with them.

Congenital cataract, traumatic cataract, and simple cataract have all been promptly cured with the aid of the imagination when it became as good with the eyes open as with the eyes closed. When one letter, a part of one letter, a period, a comma, or a semi-colon, is imagined as well with the eyes open as with the eyes closed, there follows almost immediately a temporary cure of imperfect sight. To understand how this can occur, one should demonstrate how imperfect sight is produced by an effort. It is a truth that the memory of imperfect sight has produced myopia, hypermetropia, and the increased tension of the eye in glaucoma. **School children acquire myopia by a strain to see better.** Some forms of concentration produce an inflammation of the retina similar to the imperfect sight of amblyopia ex anopsia. This must be a truth because it suggests proper treatment for amblyopia; namely, rest of the eyes.

**Amblyopia** is very frequently associated with imperfect sight, an imperfect field which may be irregular in its outline. For many years amblyopia has been considered by authorities to be incurable, but these cases have been studied in recent years so that now most authorities believe that amblyopia is usually curable. It is a fact that some individuals with amblyopia ex anopsia recover without treatment. It seems reasonable to believe, if a number of patients recover spontaneously, that the treatment suggested to achieve this result would be successful in obtaining a cure. Normal eyes have been observed to acquire amblyopia, which was increased by an effort or a strain to see. By the practice of relaxation methods the amblyopia is usually benefited or cured.

There are **diseases of the choroid** which for many years have been understood to be incurable. The fact that a strain or effort to

see may produce choroiditis suggests that relaxation methods should be practiced in order to obtain a cure. Cases of this type are too often neglected because they have not been sufficiently studied. The proper kind of mental activity benefits and cures functional or organic diseases of the eye: Some patients suffering from choroiditis obtain benefit quickly, while others take a longer time.

A man, aged 25, complained of many disagreeable symptoms. With both eyes open his vision at fifteen feet was one third of the normal. He suffered very much pain. Treatment relieved this pain and made it possible for him to read at the near point. At ten feet he read the bottom line of the test card with his right eye, a vision of 10/10. With the left eye at ten feet, he read the 50 line. In a poor light, his vision for distance and for the near point was much below the normal with either eye. When he covered the closed eyelid of the right eye with the palm of his hand, he saw a field of green which continued to be evident for part of a minute. When the eyelids of the left eye were covered with the palm of his hand, he imagined the whole field to be red, changing to yellow and orange. When he produced those colors in his closed eyelids he complained of headache, dizziness, and considerable pain in both eyes.

Some months previous each eye had started to turn in at different times. A stare, strain, or effort to see better increased the squint of the left eye. When the left eye was covered, an effort to see produced a squint of the right eye, which turned in. An operation, which was a failure, was performed on the left eye by a prominent ophthalmologist. Shortly after the operation the left eye turned out almost continuously.

The patient was nervous. His mind planned very unusual things which lowered the vision of the right eye when he stood six feet from the card. When he regarded the Snellen card at six feet and a half, only half a foot further off, his vision became much worse. When he regarded a letter at seven feet that he remembered or imagined, the vision of the right eye became normal for a few minutes. When the illumination of the Snellen test card was imperfect, his vision became very poor.

At a distance of ten feet, in ordinary daylight, his vision became normal. At twelve feet the vision of the right eye was reduced to one fourth of the normal. Most of the time the vision of the left eye was imperfect at a near distance, five feet or further. He was able to read fine print at ten inches from his eyes. At twelve inches he could remember or imagine diamond type, which he read quite readily, but at the same distance, he was unable to read print which was five times as large as diamond type. Such cases are rare.

After resting his eyes by palming for long periods of time—one hour, two hours, or longer—the vision of the right eye was improved to the normal for a few hours, but the vision of the left eye was improved to 1/20 of the normal for a few minutes only. Under favorable conditions the vision of the left eye was decidedly improved. When the light was quite bright, the vision of the left eye improved, while the vision of the right eye became worse. At twelve inches or farther, he was unable to read any of the print.

It was interesting to study his mind while the left eye was reading the Snellen test card at different distances. There were times when he could straighten the left eye when the Snellen test card was placed at five feet or ten feet. This ability to straighten the left eye was very changeable. With the right eye covered, the left eye read one half of the Snellen test card at five feet. Later the large letters of the Snellen test card were distinguished at 20 feet, while strange to say, his vision at five feet or ten feet was very poor. At about the same time he could read the Snellen test card with normal vision with the left eye at twelve inches.

It was difficult to explain or to find out why it was that there were periods of time when the vision at the middle distance was poor and why the vision at 20 feet was good. Sometimes the vision at the middle distance would be almost entirely absent. It was difficult or impossible for me on many occasions to understand the idiosyncrasies of this man's vision. Another important fact was that the patient himself could improve his vision for any distance desired by some activity of his mind which was neither a strain or a relaxation. This patient, like other and similar cases, was bothered by a large blind area which interfered seriously with his sight. There were times when he was able to increase the blind area while there were other occasions when the area lessened its size.

The activity of this man's mind was very uncertain, and neither he nor his friends could prophesy what was going to happen next. He discontinued coming to me before he was entirely cured and I have not heard from him since.

**Glaucoma** is a very serious, treacherous disease of the eyes. The principal symptoms are hardness of the eyeball and a contracted field with imperfect sight. By prescribing rest or relaxation of the eyes all cases of acute glaucoma have been benefited.

Recently a number of patients were seen suffering from a mild form of glaucoma. Usually the field was contracted on the nasal side, but there were periods of time when the contracted field was on the temporal side. One patient could consciously manipulate the size, form, and location of the blind area of the field. A large letter which would appear about three inches in diameter, when regarded by an eye with normal sight, would seem to some cases of glaucoma to be only an inch or less in diameter. The large letter which was seen by the normal eye to be a dark shade of black would appear to some patients as brown, lavender, yellow, or fiery red when regarded at fifteen feet or farther. At twelve inches the letters of the Snellen test card might have almost any color.

The letters might appear to be single, double, or more numerous. Every other line of letters would appear to consist of a number of letters instead of being seen properly one at a time. The mental strain to accomplish this consciously was not understood. As a matter of common sense, one would expect that if one line of letters was seen double, all the lines of letters should be seen double. Sometimes the letters of one line would be apparently one above the other. Sometimes the double images appeared to be slanting. The ways that the patient mentioned that he was able to have imperfect sight were very numerous. One of the peculiarities of his case was that he was able to see small letters more clearly than large letters. The different ways that he could see imperfectly with the left eye were not duplicated with the right eye.

Another patient, a girl with a very high degree of near-sightedness, had difficulty in finding a way which would produce some improvement in her sight. After spending a good many months in studying the problem and in trying various methods, she became able, with the aid of a rectangular swing, a swing which was accomplished by moving one hand in a rectangular direction, to obtain benefit. A finger of one hand was moved in such a way that she appeared to be drawing a rectangle, three feet by one foot. The patient was very much thrilled to find that the improved vision occurred at the same time that she produced the rectangular swing.

(Original, partial versions of the modern Infinity, Figure Eight swing.)

Some patients improved their vision by practicing the vertical swing; others, by practicing the oblique or horizontal swing, obtained an improvement in the sight. The more the facts were investigated, the greater became the evidence that it is a mental strain which lowers the vision and not a local strain of the eye itself. In all cases of imperfect sight a mental strain can always be recognized. When this strain is relaxed, the vision always improves.

In the treatment of imperfect sight by eye education, the results should be obtained very promptly. One soon becomes able to remember many other ordinary objects besides the letters of the Snellen test card. **When the memory becomes as good with the eyes open as with the eyes closed, the mental strain disappears and the vision becomes normal.** This suggests that by

Double image of the letter E caused by imperfect vision. Shift on the letter, part to part, blink, relax, use central fixation and the letter will merge into one clear image.

practicing with the Snellen test card at a near point—three, five, or ten feet—the memory will become more nearly normal.

Patients with high degrees of myopia have been cured very promptly, perfectly, and continuously by the memory of perfect sight.

It is very important that mental activity be understood, because imperfect sight is not possible without a mental strain. When a patient with very imperfect sight is benefited or cured by relaxation methods he is very much inclined to say that he does not see the letters on the Snellen test card—that he just remembers or imagines them. The mind of the patient with imperfect sight will always imagine things wrong, although the patient may not be conscious of this fact. For example, he may see a large letter E at fifteen feet, and make the statement that it is not a letter E, but that it is a letter O. The patient may argue about that for some time. When he is told that it is a letter E, he says that it can't be a letter E, that it must be something else.

In short, most patients are more apt to miscall large letters than to miscall small letters. Sometimes the letter E is not imagined or seen until the letter is brought a foot or two away. Then when the letter becomes known by regarding it at the near point, it may gradually be taken farther away and still be seen as a letter E. The next day when the E is regarded, it may not be seen, although it is known to be an E. It may be necessary to place the letter E closer to the patient again before it is recognized.

I have repeatedly stated that it is usual for patients to see a known letter better with the eyes closed than with the eyes open. In the treatment of such cases one should realize that the number of ingenious methods employed to make the sight worse are sometimes very remarkable. If the patient knows what is wrong with his eyes, the knowledge is a great help in obtaining a cure. Some patients have been told a number of times that when they know what is the matter with their eyes or their sight that they are more readily cured. By repetition, the vision of most people has been permanently cured.

Staring, squinting, not shifting on a letter and remembering, imagining it unclear causes strain and blur.

Experiencing this teaches the person to avoid it.

There are many ways of securing relaxation, but the best one of all is the simplest. The perfect memory of a house or a chair is a great help, but one obtains still greater assistance by the memory of a very small part of a chair. The smaller the object, the more perfectly can it be remembered, imagined, or seen. After the patient becomes convinced that he is suffering from a mental trouble as well as an eye trouble, progress toward a complete recovery in a very short time is obtained. Patients with a high degree of myopia have been cured by the memory of one half of a large letter, but others have been cured more quickly by the memory of a smaller area. Large letters are not seen, remembered, or imagined as well as small periods.

## Presbyopia

By EMILY A. BATES

PRESBYOPIA is middle age or old age sight. When people who are troubled with presbyopia try to read fine print at the near point, or even try to read ordinary type at the reading distance and fail, they usually put on eyeglasses to correct their trouble. If the trouble is slight and the correct glasses are worn only when it is absolutely necessary, there is not much damage done. If the wrong eyeglasses are prescribed there is sure to be trouble ahead. When eye glasses do not fit right or the wrong glasses are worn, the patient usually suffers from headache or he tires sooner than a person with normal sight.

People who have myopia or near-sight sometimes obtain normal vision just by removing their glasses and not wearing them again. Reports of such cases come to us from time to time. Those who have acquired presbyopia, however, and have worn glasses for a considerable length of time do not find it so easy to do without glasses, either for reading or doing fine work at close range. Such cases need supervision in order to bring back their sight to normal.

I had a patient over 60 years of age who wore glasses for 25 years for the correction of presbyopia. She was told by an eye specialist who fitted her with glasses that in time she might be able to do without her glasses and if she lived long enough she would have what is called "second sight." Instead of this happening, her vision gradually became worse and her bi-focals had to be changed three times during the 25 years. She gradually became deaf in her left ear and could only hear a loud noise like an automobile horn or a whistle if the sound was near. There was a swelling below her lower lids and her forehead was wrinkled much like that of an older person. When she did not have her glasses on, the wrinkles became more numerous as she tried to see at the near point.

Her vision when first tested was 15/20 with each eye. Resting her eyes by keeping them closed for over a half an hour improved her vision to 15/10. The long swing, counting up to 100 as she swayed from side to side, caused the wrinkles of her forehead to disappear temporarily and her eyes looked more natural than they did when she first came to me. I placed her before a long mirror and asked her to sway backwards and forward with me, as she put her right foot out about a foot farther than the left. I told her as she swayed before the long mirror to look down to the tip of her shoe, and as she swayed backward to look in the mirror at the top of her head. She said that she could feel the strain leaving her, so she kept that up for a considerable length of time, alternately placing the left foot out farther than the right and vice versa.

Occasionally she would make a mistake and not look at the tip of her shoe as she swayed forward and when she swayed backward, she seemed to forget to look at the top of her head. I had to watch her almost constantly to keep her swaying properly so that she would keep up the relaxation that caused her discomfort to become less. She came to me daily for a week and at the end of that time, she noticed that the baggy condition under the lower lids was considerably reduced. She had spent three hours each week at the masseur and had received all sorts of facial massage and treatment to help her get rid of her wrinkles and the baggy condition of her eyelids. Now, in one week's time with daily treatment, spending a little over an hour each day with me, she found that the Bates method was doing something that she had not expected.

When I tested her vision for fine print, she held the little Fundamental card with graduated type at arm's length. She could see the Figure 1 for Sentence No. 1 and the Figure 2 for Sentence No. 2. She could see that there was black print on the rest of the card, but she could not make out words or sentences. Neither could she imagine that the sentences were divided by white spaces. I made her comfortable in an arm chair and told her to keep her eyes closed—palming if she cared to—but at no time was she to open her

Long Swing  
Swing and turn left and right.

- + Sway, rock the body left and right.
- + Rock forward and backward.
- + Roll back and forth on the feet: heel to toe, toe to heel.
- + Then move, rock forward and backward by walking a step forward and backward. Alternate with the left foot forward for a while then right foot forward.

Sway forward and backward in front of a mirror. Follow Dr. Bates directions.

eyes until I told her to.

The memory and the imagination always help the sight when things are remembered or imagined perfectly. I explained to her that in order to imagine something it would have to be seen first. To imagine something which is explained to her, but which has not been seen, would cause her to have an imperfect imagination.

#### Memory, Imagination Example - Gardening

This patient traveled a great deal but when she was at home, she attended to a beautiful garden of flowers, which beautified a section of her home overlooking a lovely spot on the Pacific coast. She mentioned an orchid in the bud and how beautiful it seemed to her when it was in full bloom. She mentioned the different flowers which needed her daily attention to help them grow from the seed to the flower in full bloom. In this way, she remembered the seed as she planted it, then the little green speck as it appeared above the dark soil, then later with the warmth of the sunshine and fresh water that she gave the little flower each day, she saw the little plant grow into a living thing lovely to look at. She had a perfect imagination and memory for plants and flowers and as she explained these things to me, her mind became relaxed and when she opened her eyes to read the Fundamental card, which I had placed twelve inches from her eyes instead of arm's length, she read all of Number 8 of the Fundamental card.

She made only one mistake when she first began to read Sentence Number 8 and saw the word "variable" as "vegetable". She knew immediately that she had seen the word wrong, that it must be something in connection with the swing, and that it could not be a "vegetable." I told her to place her finger directly below Sentence Number 8 and told her to shift slowly from the white spaces above sentence Number 8 to the sentence below, directing her all the time to blink as she shifted this short distance. She did this faithfully as I directed her to do and then she read sentence after sentence to Sentence No. 15, which she read without any trouble. She became hysterical as she finished reading this little card and her gratitude was most profound.

To be sure that she would practice properly while she was away from me, I told her to hold the Fundamental card again at arm's length and to look at the sentences without blinking or shifting. Immediately the whole card became blurred and she could not read at all. She asked me not to have her do that again because it gave her pain and discomfort in her eyes. It was necessary for me to have her do this, however, because she would have done this same thing without knowing it. Again I had her close her eyes, using her memory and imagination and before she opened her eyes again, I held the Fundamental card six inches from her eyes instead of twelve inches as we did before. Holding the card in my own hand she did not realize how close it was to her closed eyes. When she opened her eyes and read all the sentences of the Fundamental card, she did not realize that I was holding the card so close to her eyes. We measured the distance to be accurate about it and when she found out how much she had improved, she was quite sure that she understood the method enough to go on by herself.

Thinking that the eyes cannot see at a specific distance blocks vision improvement.

Thinking positive, knowing the eyes can see clear at that distance results in clear vision.

I saw her recently for the first time in about two years and her ability to read at the near point has not changed during that time. I asked her if she had stopped practicing after she found that her vision had become normal again and her answer was "No, indeed, I have been very careful to give my eyes enough time for practice every day since I came to you for treatment." This is another proof that if patients carry on the work by themselves after they no longer receive personal attention, that the vision does not go back to where it was before the Bates method was first practiced.

Another patient, aged 58, first put on glasses at the age of 30 for the relief of headaches. At her first visit she had with her the four pairs of glasses which she had worn from the time she had first started to wear glasses. She gave me her history, explaining that she looked at figures all day long, being a bookkeeper and accountant for a large corporation. She said that the first glasses she wore gave her instant relief from pain until one day about a year later she received a shock which caused her great sorrow. She had lost a member of her family whom she loved dearly and this caused a great deal of depression. Feeling that her glasses needed to be changed, she called on her oculist who gave her another pair. She did not wear them constantly because they did not give her much relief or help in her work. Again she had them changed with better results this time and she got along very nicely with these glasses until shortly before she came to me to be relieved of eye glasses altogether.

When Dr. Bates examined the first pair of glasses she had worn, he said that they were plain window glass. I explained to my patient that apparently the mental effect which the glasses gave her when she put them on was what helped her, and not the glasses themselves. When she received the nervous shock which caused depression and sadness in her life, she undoubtedly strained her eyes, which caused imperfect sight.

The second pair of glasses, not suiting her properly, probably made the condition of her eyes worse. At any rate, when Dr. Bates examined her eyes, he said that she had mixed astigmatism with presbyopia. I am sorry that there are not more eye specialists who find it a mistake to exchange eye glasses for stronger ones for those who came to them for relief of their eye trouble. In this particular case eye glasses did not help and the patient was grateful to her friends who recommended Dr. Bates and his treatment for the relief of eye strain.

With the right eye her test was 15/40, but none of the letters were clear or distinct. Her left eye had normal vision, 15/15, and she saw all the letters clearly. Palming, and mental pictures also helped this patient and she found the long swing most helpful in obtaining relaxation of the mind and body before starting out to her work each day. She appreciated the fact when it was demonstrated to her that when she looked directly at print without shifting an eighth of an inch or less away from the point where she was reading, the strain became worse and the pain and discomfort she had from the stare and strain was increased.

This last sentence actually means: Look directly at the letters when reading them, and keep the eyes moving, let the eyes move around, shifting from part to part on the letters, and from letter to letter, word to word. Staring, eyes immobile, locking the eyes on one part of a letter causes strain and unclear vision.

Modern teachers state that reading through the center of the words activates central fixation, eye movement and clear vision.

The reader can also let the eyes move freely in any direction on/along the letters.

I improved her right eye to 15/15 in less than an hour's time, which, of course was only a temporary improvement. I did not have much trouble in teaching her to read fine print and to see figures by shifting (from part to part on the figure and from figure to figure) and noticing the white (glowing bright white) spaces between lines of type and figures.

She needed only one treatment with instruction for home practice to restore her sight to normal. She corresponded with me regularly several times a month, just sending reports of the progress she made or the difficulty she had in practicing certain things before she started out to business in the morning and before retiring at night. She was told to return for another treatment if she found it necessary, but apparently she did not need it because I did not see her again.

Follow the dots: Shift point to point (dot to dot) on the apple and E to see them clear. Blink, relax.

The most important thing for people who have presbyopia or astigmatism or any other trouble which causes imperfect sight is to avoid looking at reading type or at anything, in fact, without shifting or blinking, which is something the normal eye does frequently all day long.

## Announcement

Dr. Bates takes pleasure in announcing that Dr. John A. Rath of 111 North West Ave., Jackson, Mich., has recently completed a course of instruction under him and is fully qualified to practice the Bates Method.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES  
NOVEMBER, 1929

### Improve Your Sight

- + When convenient, practice the long swing. Stand with the feet about one foot apart, turn the body to the right, at the same time lifting the heel of the left foot. The head and eyes move with the body. Now place the left heel on the floor, turn the body to the left, raising the heel of the right foot. Alternate.
- + Rest your eyes continually by blinking. The normal eye blinks irregularly but continuously. When convenient, practice blinking in the following way: Count irregularly and blink for each count. By consciously blinking correctly, it will in time become an unconscious habit.
- + When the mind is awake it is thinking of many things. One can remember things perfectly or imagine things perfectly, which is a rest to the eyes, mind, and the body generally. The memory of imperfect sight should be avoided because it is a strain and lowers the vision.
- + Read the Snellen test card at 20 feet with each eye, separately, twice daily or oftener when convenient. Imagine the white spaces in letters to be whiter than the rest of the card. Do this alternately with the eyes closed and opened. Plan to imagine the white spaces in letters just as white, in looking at the Snellen test card, as can be accomplished with the eyes closed.
- + Whenever convenient, close your eyes for a few minutes and rest them. Palming.
- + Sunning. Go outside and expose the eyes, skin to Full Spectrum Sunlight daily.

## Amblyopia

Dim, low, no vision in one or both eyes.  
Usually occurs with squint or advanced eye problems but can occur alone.

By W. H. BATES, M.D.

WHEN the sight is poor and cannot be improved promptly by glasses, the cause is usually due to amblyopia. The word amblyopia means blindness. **In amblyopia the vision is less in the region of the center of sight.** One cannot have imperfect sight without having at the same time a measure of poor vision in which all parts of the field are involved. It seems curious that it is possible for the most sensitive part of the retina to become blind while other parts of the retina have considerable vision, better, in fact, than the vision obtained by the activity of the center of sight.

Some cases of amblyopia cannot count fingers. Many others have no perception of light and yet, strange to say, the advanced cases can oftentimes be cured just as quickly as other cases in which the vision is only slightly lowered. Some cases of amblyopia may have poor vision at a distance of fifteen or twenty feet, a similar reduced vision at six inches or less, but at ten feet the vision may be nearly normal.

### Color Blindness

In most cases of **amblyopia** the field of vision is usually very small. Sometimes the letters regarded at fifteen feet appear to be blood red while other letters regarded at three feet may seem to have a tint of green or some other color. The perception of colors varies greatly at different distances. Red may look like green when the card is regarded at fifteen feet or farther—yellow may give one the appearance of blue.

For many years **color blindness** has usually been considered incurable, but since **amblyopia and color blindness are usually found together, the treatment which helps or improves the sight without glasses also benefits the color blindness.** The reverse is also true; when color blindness is benefited the amblyopia becomes less.

Since it is a truth that staring, concentration, causes imperfect sight, any treatment which relieves strain should always improve the sight or improve the vision in amblyopia and color blindness. A great many lives have been lost as a result of acquired color blindness. A patient with imperfect sight was brought to my office by his family physician with a history of having run into another automobile while driving his own car. When I tested his vision with the Snellen test card, I found it to be normal.

The patient was very much upset and said in his defense to me: "Doctor, I never saw that automobile." A good deal of time was spent in demonstrating that the patient had acquired amblyopia which was so complete that he really did not see the other car, but the blindness had lasted for such a short time that it was not an easy matter to prove that he had an **attack of temporary**

### blindness or an attack of amblyopia.

This phenomena has occurred very often to locomotive engineers who would state after an accident that they had suddenly gone blind for a short time and when they were blind they did not see the danger signals.

One patient, a **sea captain**, told me that he believed that for his own safety and that of his passengers he ought to give up his occupation because he was having more and more frequent attacks of imperfect sight from amblyopia. At one time his vision was very good and he had no trouble whatsoever in seeing a lighthouse on the shore many miles away, but recently he had attacks of blindness which prevented him from recognizing the officers and sailors on his ship.

The popularity of the airplane has increased in recent years. Every once in a while a report is published of some flying machine failing to the earth and causing many deaths, because of attacks of sudden blindness suffered by the **pilots**. An aviator once visited me for relief. He said that some years previous he had been very much concerned about the action of his machine. The machine would start to fall, but would stop before reaching the ground. He lost control of it in the beginning, although he was positive that he acquired control again. After he had rested for a month or more, he still had the attacks of temporary blindness which cause him to lose control of the plane, although they were not so continuous.

He was told that the cause of these sudden attacks of blindness was eyestrain. The eyestrain was treated by the usual methods and treated so successfully that he drove a car for long periods of time without further attacks of sudden blindness. At one time he reported to me that if he took the trouble to practice relaxation methods he had no attacks of blindness. He was convinced that the relaxation methods prevented amblyopia and loss of mental control.

There are other occasions when these attacks of amblyopia with color blindness have interfered with the work of some **artists**. A portrait painter gave a history of attacks of temporary blindness while at his work. Sometimes after devoting considerable time to his work he found that he had to do it all over again because of the attacks of amblyopia and color blindness.

In another case a well known **surgeon** suffered from attacks of blindness at irregular periods. The blindness was complete so that he had no perception of light. The attacks of blindness worried him very much because he was afraid, while performing an important or dangerous surgical operation, that in the midst of it would come an attack of sudden blindness which would tend to interfere seriously with his work.

The neurologists whom the surgeon consulted all told him that he was threatened with insanity and that unless he took a long rest he might unexpectedly find himself blind and insane. Every ophthalmologist whom he consulted gave him a different pair of glasses to wear, none of which gave him any relief. He not only suffered from attacks of blindness but he was also bothered by illusions of sight.

He said nothing about the amblyopia at his first visit, but told me that he called to have something done for his eyes. He had many symptoms of discomfort and he would be very much obliged to me if I would cure him. While examining his eyes with the ophthalmoscope and seeking to find some treatment which would improve his vision, I discovered that he was suffering from amblyopia. Then he was told that the reason that his sight failed and that he had attacks of double vision was because of this amblyopia. Then began a great battle. The doctor knew a great deal about physiological optics and would not encourage me to treat him until he was convinced that I was right and he was wrong.

#### Double vision, multiple images

When he was in his office he said that where he knew there was only one light, he saw two, three, or four lights. The images in some cases were arranged one above the other and the distances between them varied within very wide limits. He said, however, that the principal illusion that he suffered from was that it seemed to him that his hands and feet were double, sometimes more than double. The size of the double images varied; sometimes one image was four or five times as large as the other. In some cases the double images were arranged one above the other, while in other cases they were arranged in an oblique direction. When he looked at a Snellen test card hanging up in my office, the bottom lines were double and the color of each line of letters appeared different. With the aid of central fixation this illusion disappeared and did not return.

Double vision caused by squint, crossed/wandering eyes is different from double, multiple images which can occur in one or both eyes and are usually caused by imperfect relaxation of the mind and eyes, eye muscles, imperfect eye muscle coordination, abnormal eye, cornea, lens shape, left and right brain hemispheres not activated, integrated, resulting in astigmatism, abnormal images.

A little double image effect can occur temporarily when the vision is improving from blurry to clear. The double, multiple images appear but are basically clear and will merge into one perfect clear image as the mind, eyes, eye muscles continue to relax, function correct.

Tension, pressure on the nerves, muscles in the neck can resonate into the eyes/eye muscles and cause double, multiple images, blur.

Relaxation and movement of the neck along with all Bates Method activities corrects these conditions.

To satisfy the surgeon I made repeated examinations of his eyes with the aid of the ophthalmoscope and each time I reported that his eyes were all right and that there was nothing in either of his eyes which could explain the illusions from which he suffered. They did not come from any malformation of the interior of the eyeball but were imagined. He was very much impressed when I told him how to produce illusions of sight consciously whenever he so desired. He discovered that it was necessary to strain in order to do this and knowing the cause of his trouble made it easier for him to relieve it by doing away with the strain.

This doctor went through the **World War** and when he returned he came to my office and thanked me for what I had done for him. He said that he had not had a single attack of temporary blindness from the stare or strain of amblyopia, because knowing the cause of his trouble he was able to prevent it.

The great mistake that has been made for the last one hundred years or more was in ignoring amblyopia. It was astonishing to find the number of doctors who did not believe that amblyopia was of great importance. Time after time patients with amblyopia

Bates method:  
shifting, central  
fixation, relaxation,  
movement, memory  
and imagination  
looking at familiar  
objects... keeps  
sailors, pilots...  
vision clear.

were treated in my office with success by relaxation methods. Some doctors stated very strongly that amblyopia was congenital and emphasized the matter so strongly, so continuously that most other doctors hesitated to treat amblyopia at all, but were very glad to turn such cases over to someone else.

## Amblyopia

By EMILY A. BATES

AS DR. BATES' article in this issue is on amblyopia, I thought that it would be a good opportunity for me to tell about some interesting cases which I have taken care of.

In 1912 when I first began assisting Dr. Bates in his experimental work in the Physiological Laboratory of the College of Physicians and Surgeons in New York I had no idea that there was so much to be learned about the cure of imperfect sight without glasses. As I became more acquainted with the Doctor's work, the desire to learn more grew stronger. Each day I helped him. Watching the Doctor in his experiments with animals (these experiments were always performed immediately after the death of the animals) was most interesting and often students in the Physiological Laboratory who were doing their experimental work would stop long enough to watch Dr. Bates doing his work and making new discoveries.

I felt very proud then to stand by his side after our work at the office was finished, taking an hour before clinic time and an hour after the clinic session was over. There were times when our work together seemed almost too strenuous for me and many times I felt as though I could not go on another day. Before I offered my assistance there were doctors who tried to keep on in assisting the Doctor until his experimental work was accomplished, but in due time, one by one, they had to give up, because they could not spare enough time away from their offices and for other reasons.

Dr. Bates has always been a great reader and has studied every book written by prominent eye specialists. He always found time enough to try other ideas and experiments even while he was doing his own work. While other doctors were away for the summer months, enjoying a rest away from their work, Dr. Bates, who did not at that time believe in vacations, would sometimes be the only physician doing any experimental work at the laboratory. Occasionally Professor Lee, who in his heart believed in Dr. Bates' work and respected his ability to do what other doctors failed to accomplish, would come into the room to watch the experimental work going on.

Amblyopia not only occurs in human beings but also in animals. Anyone who doubts this might ask the keeper of the zoo how an animal in captivity acts when he is under a strain. In the early spring, when animals that have been housed for the winter months, because they cannot stand the extreme cold, are first given the fresh air and more space outdoors, they wander around and about in a blind sort of fashion. Some of them toss their bodies against the tall railings which prevent them from escaping and for a while they do not know what it is all about. After a while, when they become accustomed to their new surroundings and different light, their temporary blindness wears away, and if anyone who understands the use of the retinoscope is near he will find that there is nothing wrong with the interiors of the animals' eyes.

Having had the opportunity of being with Doctor Bates during his experimental days, I was able to understand how something could be wrong with the eyesight of school children when apparently there was no organic change in the retina. I made a special study all by myself of the cure of the eyes of school children and this is what I found:

Usually children of the poor have very little or no idea of school work before they enter the school room. When it comes time for the mother to take her child to the public school, usually the mother does not know what is in the heart or the mind of that child. He has been accustomed to a little play each day in the streets and at other times was happy and familiar in the surroundings of the little place called home. Usually children are shy when visitors call; some become irritable for no reason whatever and are sometimes punished for that. The mother does not realize that strain of the mind is produced because the child either likes or dislikes the visitor. House pets such as dogs or cats which are accustomed to the members of the household usually run away and hide when a visitor calls. It doesn't require much to cause mind strain and when there is strain of the mind there is always eyestrain.

When a child is brought into a large school he feels as though he is in another world. The child meets children who seem different from those with whom he has been acquainted. He meets a teacher who tries her best to become acquainted with him and doesn't always succeed. He sees his mother leaving him to the care of those whom he has never met before. All these things have to be overcome, and this is not readily done in every case.

After a while the tests begin. Children soon have to read the writing on the blackboard. When this cannot be accomplished by the pupil it is understood that the child has imperfect sight and needs glasses. Eye tests are made with the aid of the Snellen test card and it is found that the vision is not normal. (Even the sound of the voice of the person who tests the vision has a mental effect on the child.) Then the mother receives a note saying that the child needs to be fitted for glasses.

In some schools this is still going on, but in others it is not. I found many schools using the Bates Method without calling it so. Schools in New Jersey have used the Bates Method successfully for many years, and while it has been stopped by the authorities as a daily routine, there have been a large number of children benefited by the use of the Snellen test card. In the larger cities of the United States as well as in Germany, South Africa, Great Britain, Switzerland, and Spain, the Bates Method is being carried on.

A great deal of eyestrain could be prevented if children were told what to do before they begin their studies. Amblyopia could be prevented by explaining to the child how necessary it is not to stare in order to see better. Blinking irregularly but often is something that is done universally by people who have no trouble with their eyes. Animals in the same way blink their eyes often, although they themselves are not conscious of it, as far as we know. **When blinking is done right the eyes move and it is seldom that amblyopia is observed in people who practice this.**

In the October issue of the magazine, "Good House-keeping," there is an article entitled "A New Job for the Public Schools," by Elizabeth Frazer. Her illustration of the children studying at their desks shows mental strain as well as eye strain. In the article the following appears: "What is the matter with these children? What causes them to fail in schools? What can be done to help them? Progressive educators are beginning to ask these questions and want to help to prevent failures."

I can tell them how, for I have been with school children a good many years and have helped them along just by improving their eyesight to normal. All those who are unruly should have their sight tested every day with the Snellen test card. I can prove, if I am given a chance with a group of such children, that every one has eyestrain. I can prove that when eyestrain is entirely relieved by resting the eyes, the mentality of such children is improved. Not only does the child benefit by the Bates Method of relieving eyestrain, but the mother is relieved of a great problem and the teacher is able to teach with less mental strain for her. I am ready for an interview at any time and I shall greet with pleasure anyone who is interested enough to let me help in improving the defective eyesight of school children.

## Squint

During the nine years of clinic work which was done by Dr. Bates and myself at the Harlem Hospital here in New York City, many such cases as Elizabeth Frazer describes came to us to be fitted for glasses. In my book, "Stories from The Clinic," I wrote about a case of squint or cross eyes. This particular case was a little mulatto boy who first came at the age of four years, accompanied by his grandmother. He wasn't wanted in kindergarten because he was not only unruly but destructive. He was not wanted in his home where a new baby had come and where he was not safe to have around because of his cruelty. His grandmother was the only one who cared to bother with him. When he had fits of extreme nervousness, he would act exactly like a blind person and yet he was not blind. This is amblyopia.

I had to be very patient with this boy in order to do anything with him at all. His right eye turned in toward the nose so far that one could hardly see the iris. One could easily imagine the mental strain that this caused the child. Glasses had been prescribed for him, but with such a nature as he had, how was it possible to prevent the glasses from being broken? This little chap refused to wear them from the start. The family physician did not know what to do for him because physically he seemed all right and he did not know what to do for him mentally. Through some mother who had brought her child to us for treatment and whose child also had squint, this grandmother heard about Dr. Bates and his relaxation treatment for the relief of tension and eyestrain.

When I gradually won the boy over, we had to play a game at pretending. We went into the land of make believe while his eyes were closed. I also had to close my eyes frequently while treating him, because he produced a strain in my eyes as well as in his own. It was the only way I knew to treat him and obtain results. His grandmother watched him closely each time I gave him a treatment and she followed me as well as she could when she treated him at home. **When the sight of his right eye improved for the test card, the right eye became straighter and he displayed less nervousness.** He attended clinic regularly three days a week for some months and each time he received a treatment he became more and more patient and did as he was told by me.

Each time I tested his sight for the test card I made note of the improvement he made and so did his grandmother. He did not always do as he was told but a decided change for the better was noticed in due time and then he and his grandmother stopped coming to the clinic for a while. I did not hear from them for a year, but when he did return I did not know who he was when he spoke to me. Both eyes were straight and his vision was normal for the test card. His grandmother had brought him to me to let me see the improvement in her little boy and I was surprised to note the difference in his attitude toward her and toward me. She had helped him for an hour every day and had used the test cards as I directed her. He had in the meantime returned home to his mother and was again going to school.

A boy, aged fifteen, was brought to my attention through a patient who was treated and cured by Dr. Bates. This former patient was Mrs. H. D. Messick of Cleveland, Ohio, who has done a great deal of charity work in relieving eye strain in school children among the poorer classes. She heard of this boy whose left eye was almost blind and whose vision for the right eye was 10/30. The best eye specialist in the middle west pronounced the left eye incurable and advised him never to be without glasses for fear of going absolutely blind in the other eye. The eye which was almost blind was examined with the ophthalmoscope and nothing could be found wrong with the retina or optic nerve or any other part of the eye, yet he could not see out of that eye.

**This is amblyopia or blindness without any apparent cause.** The patient does not know what is wrong; neither does the doctor, yet the patient cannot see. This boy had for many years tried to improve his ability as an artist by drawing pictures of ships, but he always drew them imperfectly because he could not see them perfectly. When this boy, who was well acquainted with the Doctor's cured patient, found out what had been done for her he promised to do anything he was advised to do if he could receive help as she did. If only he would not go blind in the one eye, he said, he wouldn't mind it much having one blind eye, and the great specialist who had pronounced his apparent blindness incurable had no hope whatever for that eye.

With such thoughts in his mind I first began to treat him. When he noticed how quickly the vision improved in the blind eye, he went to work with the Bates Method as no other boy under my supervision has done since. He improved steadily, sending me reports regularly until the vision of the poor eye was normal. This was due to the help and encouragement he received from Mrs. Messick. The teachers in school knew that he had worn glasses and when he returned to school without them, they attempted to persuade him to wear them, but he wouldn't and he said that they were thrilled to notice the improvement not only in his eyesight, but in all the class work that he did under their supervision. He sent me a picture of a ship which he had drawn, after his vision became normal. "It is as perfect as any drawing could be," Dr. Bates exclaimed after he had examined it.

What was done for one boy can be done for other boys who need help as Elizabeth Frazer has explained so well in her article.

## Notice

Dr. Bates, as well as the Central Fixation Publishing Company, has been receiving a number of letters recently from people who have been unsuccessfully treated by practitioners who have not taken Dr. Bates' course of instruction and do not understand the Bates Method thoroughly.

Dr. Bates gives a course of instruction to doctors, teachers, nurses, and others who wish to practice his method professionally. At the end of the course the student receives a certificate authorizing him to help others by the Bates Method. This certificate, however, does not authorize the student to instruct others so that they may in turn teach the method. Those wishing further particulars may obtain them by writing direct to Dr. Bates at 18 East 48th Street, New York City.

## Questions and Answers

Q - My trouble is cataract. Shall I cover up the good eye while practicing?

A - Practice with both eyes together until your vision is normal. Then, cover the good eye and improve the vision of the poor eye.

Q - Often, when I am trying to see a thing, it will come to me, but my eyes will commence to smart and then I blink and lose it. What shall I do to overcome that?

A - Blinking can be done correctly, and it can be done incorrectly. You strain while you blink. The normal eye blinks easily and frequently. Strain is always accompanied by the stare. By standing and swaying from side to side so that your whole body, head, and eyes move together, the stare is lessened.

Q - What causes redness and smarting sensation of the eye even when plenty of sun treatment has been given? Should one continue with sun treatment under the circumstances?

A - Take the sun treatment frequently for five or ten minutes at a time daily, increasing the length of time until the eyes become accustomed to the sun. The eyes should always be benefited after the sun treatment, and one should always feel relaxed. When done properly, the redness and smarting should soon disappear. If the eyes are not benefited, it is an indication that you strain while taking the treatment. Alternate the sun treatment with palming or closing the eyes to rest them. Move the head side to side when sunning.

Q - Is resting the eyes by palming a more effective cure for smarting of the eyes than the sun treatment?

A - This depends upon the individual. Some are benefited more by palming, while others receive more benefit from the sun treatment.

Q - Should motor goggles be worn as protection against wind?

A - No protection is needed against the wind if the eyes are used correctly. Blinking, shifting, central fixation, and the imagination of stationary objects to be moving, should be practiced while motoring, and, in fact, all the time. Motor goggles weaken the eyes and make them sensitive to the sunlight.

Q - Is age a factor in the cure of imperfect sight without glasses?

A - Age is not a factor.

Q - In palming should one close the eyes tightly?

A - No, easily and naturally at all times.

Q - When you suggest new methods do you mean to discontinue with the old?

A - Not necessarily; all the methods I recommend have relaxation for their object. It is for the patient to determine which treatment is most beneficial and to continue its practice faithfully. Some patients tire easily when one thing is done continuously. For this reason several are suggested in order to vary the practice.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

DECEMBER, 1929

### The Flashing Cure

**Do you read imperfectly? Can you observe then that when you look at the first word, or the first letter, of a sentence you do not see best where you are looking; that you see other words, or other letters, just as well as or better than the one you are looking at? Do you observe also that the harder you try to see the worse you see?**

**Now close your eyes and rest them, remembering some color, like black or white, that you can remember perfectly. Keep them closed until they feel rested, or until the feeling of strain has been completely relieved. Now open them and look at the first word or letter of a sentence for a fraction of a second. If you have been able to relax, partially or completely, you will have a flash of improved or clear vision, and the area seen best will be smaller.**

**After opening the eyes for this fraction of a second, close them again quickly, still remembering the color, and keep them closed until they again feel rested. Then again open them for a fraction of a second. Continue this alternate resting of the eyes and flashing of the letters for a time, and you may soon find that you can keep your eyes open longer than a fraction of a second without losing the improved vision.**

**If your trouble is with distant instead of near vision, use the same method with distant letters.**

**In this way you can demonstrate for yourself the fundamental principle of the cure of imperfect sight by treatment without glasses.**

**If you fail, ask someone with perfect sight to help you.**

## Hypermetropia (Unclear Close Vision, Farsight)

By W. H. BATES, M.D.

THE importance of hypermetropia cannot be overestimated. It is sometimes acquired soon after birth, or it may be manifest at ten, twenty, thirty, or forty years of age. Eighty percent of eye troubles are caused by hypermetropia, while near-sightedness occurs in ten percent. There are only ten percent of normal eyes. These figures are startling. The majority of persons at the age of forty-five or over acquire hypermetropia, and it is of the utmost importance that such cases be carefully studied.

Nearly everyone has the symptoms of hypermetropia. When the sight is good for distant vision, that does not necessarily mean that the sight is also good for reading at a near point of ten or twelve inches. Too often such cases are not treated seriously. Poor sight for reading (hypermetropia) is usually corrected by the use of reading glasses, while vision at all other distances is neglected.

**In middle age, serious eye diseases are caused by hypermetropia.** Among the most common are **glaucoma, cataract, and diseases of the optic nerve and retina.** In the early stages of these serious diseases, they are more readily curable than after they become chronic and more serious, because the vision is only slightly affected and **the treatment which cures hypermetropia is the treatment which prevents serious eye diseases. Cataract and glaucoma are now being prevented or cured by treatment which cures hypermetropia.** It should be emphasized that early treatment of hypermetropia yields quicker, more continuous results than later treatment.

Eye physicians or ophthalmologists have almost universally believed that absolute glaucoma is not curable by any form of treatment. It has been demonstrated that glaucoma is caused by strain—the strain of hypermetropia. When this strain is relieved or corrected, glaucoma usually improves. This treatment is more successful than operation or eye drops. It is only in the last ten years that it was discovered that glaucoma is caused by a strain which produces hypermetropia and that when this strain is relieved the glaucoma improves. I think it is a mistake to condemn this simple method of relieving the hypermetropia, which also relieves glaucoma. The eye strain which produces hypermetropia also produces cataract.

It has been repeatedly demonstrated that in all diseases of the eyes which cause imperfect sight, the eye is under a strain and when this strain is removed all diseases of the eye are benefited. Patients with atrophy of the optic nerve have good sight when eyestrain is not present. For example, a patient came from Austria for treatment of amblyopia which was so advanced that the vision in one eye was only perception of light and in the other eye it was one half of normal. She had consulted many physicians who advised operation for the cure of the total blindness. She was given the hypermetropia treatment daily for about two weeks, at the end of which time the vision was normal in both eyes. Surely if hypermetropia treatment can be so beneficial, more physicians ought to know about it. There have been numerous similar cases.

It can be demonstrated that atrophy of the optic nerve can be caused by the eyestrain of hypermetropia. Palming, swinging, central fixation have always improved the sight temporarily or permanently. It is interesting to prove that such a disease as atrophy of the optic nerve can be benefited by the treatment which relieves hypermetropia.

Patients suffering from **squint** are benefited by hypermetropia treatment. Patients with hypermetropia not only strain to produce squint with one or both eyes turned in, but they also strain to correct the imperfect sight which is caused by the squint. This fact should be more widely known, because even at this time many physicians believe that the poor sight caused by hypermetropia is incurable. (Two types of strain combined. One type of strain can lead to a secondary different type of strain.)

What is the lowest degree of hypermetropia that can be produced? is a question that has been asked. The answer is that there is no limit, not only to the low degree of hypermetropia, but there is no limit to the high degrees. In other words, by an effort hypermetropia of thirty diopters or more can be produced and, by treatment, perfect vision can be obtained just as readily.

In studying the production of high or low degrees of hypermetropia it is interesting to discover the conclusions of well known ophthalmologists. One prominent doctor was asked this question: Is hypermetropia curable? He replied that it was not curable. He was then asked, "Why do you claim that no one can cure hypermetropia?" He answered, "I know that it cannot be cured because I was unable to succeed and if I cannot succeed no one else can."

Massage of the eyelids has been recommended for the cure of hypermetropia. Another doctor claimed that he was able to cure a majority of the cases of hypermetropia, and that if the patient was not cured by massage, no other doctor in the world could succeed. Other physicians, however, did not believe that massage was a cure for hypermetropia.

Since hypermetropia is so common and produces so many different kinds of eye trouble—imperfect sight, pain, dizziness, and other nervous symptoms to a greater extent than do other errors of refraction—it is well to understand as much as we can of the occurrence, symptoms, prevention, and cure of hypermetropia.

The **best methods of preventing hypermetropia** are the **sway**, **reading fine print** such as diamond type, **palming** occasionally, and **imagining stationary objects to be moving when the eyes move in the same or opposite direction.**

(oppositional movement) The last one of these methods is not always easy to practice. Some cases are very obstinate without any known reason. They may try for days, without success, to imagine stationary objects to be moving. The cause of failure is usually due to concentration, staring, looking fixedly at stationary objects, and efforts to try to see.

When success is not attained, hold the finger about six inches from the chin while looking at distant objects and move the head and eyes from side to side, taking care not to look directly at the finger. When this movement of the head and eyes is practiced easily, continuously, the finger appears to move in the opposite direction. This method is called the **variable swing** and most people have no trouble whatever in imagining the finger moving. The length of the movement of the finger is much wider than stationary objects regarded at ten, twenty, or forty feet or farther. (Distant objects appear to move with the eyes in the same direction.)

Another case of failure occurs when the patient turns the head to the right and simultaneously turns the eyes to the left. It is a very painful experience. When one fails to obtain movement of stationary objects with the variable swing, he suffers much pain, dizziness, and other nervous symptoms.

Hypermetropia may be prevented by many other methods. The **memory or the imagination of perfect sight prevents hypermetropia in the normal eye.** The memory of imperfect sight is very difficult and the memory or imagination of perfect sight is easy.

In the city of Chicago a school teacher developed a method of treating children which prevented hypermetropia from being acquired. She had charge of about fifty or more children at the age when fatigue is common. As a result, all the teachers in the Chicago school allowed their children to rest for a time at frequent intervals—about every half an hour in two. (in two – misprint?) They were taught relaxation methods, although they were all under ten years of age. It was astonishing to observe how much they could remember, how much they could imagine, and how much their activities were improved with benefit to their eyes. Sometimes the usual exercises in the class room would be stopped and the children would be taught how to palm successfully and while palming to improve their imagination. They were taught to draw pictures which they copied from the blackboard twenty feet away. After some months, the hypermetropia was improved and finally entirely cured.

A school teacher in Long Island was treated by me for compound hypermetropic astigmatism. By the use of relaxation methods the hypermetropia and astigmatism were corrected and the patient obtained normal vision. The hypermetropia was prevented from increasing by curing it. The patient was very much pleased with the results and told the principal of her school that because hypermetropia was curable, it was also preventable. A negative proposition cannot be the truth. Hypermetropia could be prevented when it was found possible to cure it.

A number of teachers became interested and all those wearing glasses for hypermetropia were cured either by **palming** or **swinging** or by the **memory of fine print.** The principal was much pleased and placed a Snellen test card in all the cases rooms with directions that it should be read by all the teachers and pupils who were afflicted with hypermetropia. The first patient cured of hypermetropia was to continue the work.

Since she could not treat patients in the class rooms, she decided to treat them outside the school building. She made an arrangement with the teachers who wished treatment that she would teach them how to use their eyes properly and prevent or cure hypermetropia. She made arrangements with them all that after a teacher was cured, she would agree to teach, cure, or prevent

Practice with the eyes open, looking to the distance and in the imagination with the eyes closed.

Variable Swing - finger in front of face. Move the head side to side and see the finger move in the opposite direction. Practice seeing this in the imagination with the eyes closed.

some other teacher from acquiring hypermetropia. So much interest was shown by the teachers in this school building that it made an endless chain and a great many teachers and school children were cured of hypermetropia.

For many years, it has been believed that retardation is incurable. It seemed wrong that children, fifteen or sixteen years old and older should be kept in the grades with children ten years old or under. These children did not like to study. Many of them complained of severe headaches and other discomforts. Truancy was common. After retardation was cured by relaxation methods, most of the children started in and worked hard with their studies, with the result that many of them graduated into the rapid advancement classes.

I was told by many principals that imperfect sight was never found in the rapid advancement classes. Nearly all cases of retardation were suffering from hypermetropia. It was demonstrated that patients suffering from imperfect sight from any cause were also suffering from retardation. The teachers who devoted an hour or more every day to the **cure of hypermetropia** discovered much to their surprise that **almost every disease of the eye and nervous system was benefited or cured by treatment which cured hypermetropia.**

In one year, 20,000 pupils suffered from pain, headache, loss of memory, imperfect sight from hypermetropia. In one year after, 80 percent of the 20,000 children who were suffering from headaches and other nervous troubles all recovered after the hypermetropia was cured.

Reading fine print improves eye muscle relaxation, function, coordination, shape of and normal pressure on/in the eye, central fixation, shifting resulting in improved circulation of blood, fluids in the eye resulting in healthy eyes and clear close and distant vision.

## Christmas 1928

By EMILY A. BATES

AS I began to write my Christmas story, a sense of fear comes over me that I might forget to give credit where it is due, or to omit some important detail which helped to make our Christmas party, I think, the best we ever had, I should say "parties," for there were three of them.

One party was held at the office of a doctor here in New York, who specializes in ear, nose, and throat work. This doctor, with his untiring efforts, has saved the lives of many children who were suffering from a stoppage of the throat from diphtheria or some other diseases which affected the larynx and trachea. It doesn't matter what hour it may be, he is always ready to respond to a call at a time when other doctors are asleep. Both he and his nurse deserve only the highest kind of praise for the wonderful work that they are doing. Along with his private practice, he has a host of charity cases; among them are children of the slums, who would not be alive today if it were not for his skill.

The doctor's nurse gives untiringly of her time to the children who need her special care. In her kind, quiet way she explains to some patients how necessary it is to be clean. Most of these patients are little soldiers and never tell the doctor during their treatment whether it hurts or not. He knows and so does the nurse, so after the treatment is over they are usually repaid for their courage with good things to eat.

In the group assembled at our Christmas Festival were children between the ages of six and sixteen. The younger children all believed in Santa Claus and were anxious to know what he had brought for them. Mothers of some of them were present, and they shared in what there was to give.

We were quite certain at the Christmas party that the doctor was the happiest of the group. The large dining table was filled with tempting things to eat, and our Christmas fund provided all of his charges with useful gifts. Each of the boys over ten years of age received the usual necktie. Each of the younger boys received a mechanical toy of some sort, while each of the little girls received a doll; purses were given to the older girls. Boxes of good candy from Loft's, oranges, and apples were provided for all, including the mothers.

One of the poor patients of our own clinic, a woman whose sight was so impaired when she first came to us that she could not make her living, placed an envelope in the hand of our assistant, Miss Hayes, and said: "It is only a little that I have to give, but let me help someone less fortunate than I am, and you and Mrs. Bates will find that someone much better than I can." She made me think of "the widow's mite" and how much it meant to the greatest Teacher this world has ever had. When we opened the envelope we found not a mite, but ten dollars.

This woman had had what is known as compound myopic astigmatism. Her eyes at times were much irritated and the pain she suffered prevented her from doing any sort of work. She came for two years off and on and during the last year was able to earn her living again. When she first came her vision with the test card was 10/70 in the right eye and 10/50 in the left; her vision at the near point was also very poor and she had been obliged to wear glasses when she attempted to do any close work. When we last saw her, her vision had improved to 10/10 in each eye and she was able to read No. 15 on the Fundamental card at eight inches from her eyes. She no longer wore her glasses and she said that the pain from which she suffered had entirely disappeared.

Although I am usually at the office during clinic hours, the Doctor's work keeps me in other parts of our office during clinic time each Saturday morning. Miss Hayes deserves all the credit for the cure of this poor woman, as well as other cases. Not once has she failed us in taking care of her charges and the many cases which have been treated and permanently cured by her are more than grateful.

The poor woman was very happy when she learned that her money was spent to make not only one, but eight unfortunate boys, happier than they had been for a long time. These boys had their first real Christmas party in all the years of their confinement in the Home for Feeble Minded. The one who had charge over these boys was a Bates' student. She came first to Dr. Bates as a patient and after she was cured she studied the method so that she could help others. Fate and good fortune brought her to this Home for the Feeble Minded in Thiells, N. Y., where hundreds of boys and girls and men and women are confined because their minds are not normal. The eight boys who were made happy because of our Christmas fund were between the ages of seventeen and twenty years of age, but their minds were like those of little children at the age of eight years or younger. Time and again those who took care of them left because the strain was too great. Others who were less tender hearted did not handle the boys properly, which did not aid in the improvement of the minds of these poor unfortunates.

For no other reason but to be of good service Miss Anna Woessner came to take charge and see what she could do for them. The

boys responded quickly under her gentle treatment and care and changed in time from being destructive to being useful and willing to learn. Some of them had a constant desire to steal anything they could lay their hands on when she was not looking, but she did not lose patience with them or threaten them at any time. She studied their greatest faults and weaknesses and taught them right from wrong.

Although she did not mention to the heads of the institution the method that she was using to improve the minds of her charges, she went about in a quiet way, teaching them relaxation and rest of the mind and body by using the Bates Method. She allowed them to come to her room after their work hours were over and encouraged them to read her test cards, teaching them how to rest their eyes by palming.

They would do anything to hear a fairy story, so while their eyes were closed and covered they sat quietly while she told them simple fairy tales. She taught them the long swing of the body, explaining how well the big elephant could do it and how restful and happy he was because it relaxed him. She explained that relaxation meant that he was on his good behavior when he did the long swing. Even though their simple minds did not grasp everything she told them, they at least understood what good behavior meant.

Miss Woessner's mother, one of the good old-fashioned kind one reads about, always had a package for her to take back to the home after her weekend visit with her family and friends. The package usually contained homemade jellies and home-made cake which the mother prepared, arranging everything temptingly for the boys. It was always a joy to the boys to see Miss Woessner return to them. When they did wrong, they were denied the good things which she had for them. When they repented and promised to do better next time, they were always forgiven and given their share of the contents of the package.

She taught them how to make flowers of tissue paper and being an expert herself at making wax flowers, she taught them how to do this also. Some of their work was placed on exhibition for visitors to see when they called at the home. When our Christmas package arrived for them, each boy received a tie as well as candy and oranges. One of the boys sent a letter which he had written all by himself; it was hardly readable, but expressed the gratitude of each one and the letter ended by saying that he was anxious that I should receive his most precious possession, a live "bunny rabbit," as a gift.

At our own Christmas party, which was held at our new offices, there were about eight children altogether. No partiality was shown among the children so the presents that were purchased for the boys were carefully chosen so that each one received a similar gift. The same thing was done in selecting the dollies for the little girls. The men received ties and the women handkerchiefs and purses. Our tree for the clinic family seemed more beautiful than ever; it was lit up with electric lights and placed in the reception room where everyone could enjoy it.

There was one old lady who was especially happy with her gift. She had saved up enough money from her husband's small earnings during the year to buy a much needed winter coat for herself; she had also managed to buy a cheap hat and now with her new purse, she had a complete new outfit. She had been coming to the clinic almost every Saturday for about a year. She had been suffering from **cataract in both eyes**; her vision was so bad when she first came that she was unable to come alone and had to be brought to the office by her sister-in-law. She was very much frightened the first day, because, not knowing very much about the Doctor's work, she thought that he might advise operation as had other doctors whom she had consulted. She was very much relieved when she was told that Dr. Bates did not operate and that he had cured cataract without operation or eye drops. She was ready to devote as much time as necessary to home practice.

She sat in the sun every morning for an hour or longer; she palmed or rested her eyes every hour for ten minutes and practiced the long swing every night and morning. When she first came, her vision was 10/200 in the right eye and 10/100 in the left. She complained of a mist before her eyes, which was becoming worse all the time. Dr. Bates examined her eyes several times during the year and each time found an improvement in their condition. The last time her vision was tested, she could read the line next to the bottom at ten feet (10/15) with either eye and the mist which had troubled her for so long had almost entirely disappeared. It was only when she strained her eyes that it would bother her and after she relaxed her eyes it disappeared. She stopped coming soon after Christmas, before she was entirely cured, but I feel sure that she kept up her practice at home.

Dr. Bates, Miss Hayes, and I wish to take this opportunity to express our gratitude to those who added to the clinic Christmas fund and helped to make our Christmas parties possible.

## Notice

Dr. Bates, as well as the Central Fixation Publishing Company, has been receiving a number of letters recently from people who have been unsuccessfully treated by practitioners who have not taken Dr. Bates' course of instruction and do not understand the Bates Method thoroughly.

Dr. Bates gives a course of instruction to doctors, teachers, nurses, and others who wish to practice his method professionally. At the end of the course the student receives a certificate authorizing him to help others by the Bates Method. Those wishing further particulars may obtain them by writing direct to Dr. Bates at 18 East 48th Street, New York City.

## A Suggestion

A great many people who have been benefited by Dr. Bates' book, "Perfect Sight Without Glasses," Mrs. Bates' "Stories from the Clinic," or by "Better Eyesight," order copies of the books or subscriptions to "Better Eyesight" to be sent to some of their friends suffering from imperfect sight. Why not order books or subscriptions for some of your friends as a Christmas gift. We will mail books direct to the recipients, postage prepaid, and enclose your Christmas card.

## Questions and Answers

Q—Would the reading of fine print at four inches be helpful?

A—The reading of fine print at four inches is usually helpful.

Q—You mention the black period in your book. Must this be any particular size? I only imagine large round black objects like cannon balls, the center of a target, or a moving football. This is restful, but is it beneficial?

A—No. Anything that is restful is beneficial.

Q—I have attained normal vision, but after reading for a while, my eyes feel strained. Would you still consider I had normal sight?

A—If your eyes feel strained you are not reading with normal vision.

Q—Seeing stationary objects moving appears to me to be merely self-hypnotism. I can't do it.

A—When riding in a train the stationary telephone poles appear to move in the opposite direction. Of course this is an illusion, but it is a benefit to the eyes to imagine all stationary objects moving.

Q—Is it possible to cure **squint in a child under two years of age** by the Bates Method, and what is the treatment employed?

A—A child, two years of age or younger, can be treated and cured of squint, with or without imperfect sight, by the Bates Method. The treatment is varied. The swing can be practiced by the mother holding the child in her arms. If the child is able to stand or walk, it is held by the hands and the sway is practiced with the child moving from side to side. Keeping time with music encourages the child to continue the swaying for a longer time.

Improving the memory and imagination of the child is also recommended. The child is encouraged to play with toy animals and is taught the names of the different animals. Usually the animals are placed on the floor in groups and the child is asked to pick up the animals as they are named. As the child reaches for one and then another, the parent may observe whether the child goes directly toward the toy or reaches to either side of it. This method is used in extreme cases of squint where the child does not see perfectly where is looking.

Colored yarns are also used in these cases. The child is taught the names of different colors. An improvement is always noted after such treatment, because the child is constantly shifting his glance from one colored skein of yarn to the other as he selects the one called for. The problem is to educate the eyesight. The more the eyes are used the better.

Palming is beneficial in the cure of squint. If the child is told that it is just a game of peek-a-boo, he immediately becomes interested and enjoys it. Reading a story to the child as he palms is usually beneficial, and improves the squint.

With children three years or older, the pot hook card is used. This is a test card with the letter "E" pointing in various directions. The child tells whether it is pointing up or down, left or right. If a mistake is made, palming is introduced in order to rest the eyes.

Children with squint are usually unruly, disobedient or destructive. When the squint is improved, a change in their conduct is also noted. They become quiet, obedient, and their mental efficiency is improved.

See left and right brain hemisphere activation, integration, balance and other new methods for curing squint.

clear close and  
distant vision,  
healthy eyes.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JANUARY, 1930

### The Imagination Cure

When the imagination is perfect the mind is always perfectly relaxed, and as it is impossible to relax and imagine a letter perfectly, and at the same time strain and see it imperfectly, it follows that when one imagines that one sees a letter perfectly one actually does see it, as demonstrated by the retinoscope, no matter how great an error of refraction the eye may previously have had. The sight, therefore, may often be improved very quickly by the aid of the imagination. To use this method the patient may proceed as follows:

**Look at a letter at the distance at which it is seen best. Close and cover the eyes so as to exclude all the light, and remember it. Do this alternately until the memory is nearly equal to the sight. Next, after remembering the letter with the eyes closed and covered, and while still holding the mental picture of it, look at a blank surface a foot or more to the side of it, at the distance at which you wish to see it. Again close and cover the eyes and remember the letter, and on opening them look a little nearer to it. Gradually reduce the distance between the point of fixation and the letter, until able to look directly at it and imagine it as well as it is remembered with the eyes closed and covered. The letter will then be seen perfectly, and other letters in its neighborhood will come out. If unable to remember the whole letter, you may be able to imagine a black period as forming part of it. If you can do this, the letter will also be seen perfectly.**

Imagine a black letter is composed of many tiny black periods and shift continually, easy, relaxed from one period to another on the letter.

When shifting: see one period at a time darkest black and clearest in the center of the visual field as the central field moves from period to period as the eyes shift.

When a letter is seen perfect, the mental image, memory, imagination of the letter is further improved, perfected, resulting in perfect memory, imagination, relaxation, and clear vision.

## Astigmatism

By W. H. BATES, M.D.

IN ALL cases of astigmatism one meridian of the cornea is more convex or less convex than all the other meridians. One definition of astigmatism is that the astigmatic eye is not able to focus the light from the sun or from any other object down to a point. There are many authorities who claim that astigmatism is always congenital or that people with astigmatism were born with it. However, recent work on astigmatism has demonstrated that it is always acquired and never congenital. Young children, babies, when examined with the retinoscope soon after birth usually have astigmatism which is acquired by a strain or effort to see. When the child's eye is at rest no astigmatism is manifest, but when the child's eye or the child's mind is under a strain, astigmatism is always present.

Animals always acquire astigmatism when under a strain. Those who examined the eyes of cats found that it is very difficult or impossible to make them strain to see. No fish were found which had astigmatism. The evidence is worth consideration because it is based on the examination of a great many fish at the New York Aquarium. The observer with the retinoscope stood outside of the tank and was able to observe the dark cloud moving in the same direction as the movement of the light from the retinoscope. At times the fish would come very close to the glass and strain their eyes, without the production of astigmatism. I never saw a fish with nearsightedness or astigmatism. There were a number of ophthalmologists who believed that fish were nearsighted or had astigmatism.

School children are often nervous and when the nervousness is considerable, a large amount of astigmatism may be produced by a strain of the eyes or mind. When rest is secured the astigmatism in school children promptly disappears. Rest of the eyes is not always obtained readily. Closing the eyes, palming with the help of a nearly perfect memory of some letter or other object, secures a considerable amount of rest. The more perfect the memory the greater is the rest or relaxation. Rest of the eyes and mind is also obtained after the child practices central fixation or seeing best where the eyes were looking. However, it is necessary to practice central fixation without a conscious effort. When the eye is fixed on a point it is oftentimes very easy to make an effort and the effort, even when slight, is capable of lowering the vision when astigmatism is present.

There are many conditions which are favorable in securing relaxation or rest. Some people see better when the illumination is unusually good, whereupon the astigmatism immediately becomes less. There are other people who cannot stand even a moderate amount of light and their astigmatism is less when the light is poor. The distance of the print from the eyes when seen best also varies with people. In some cases letters or other objects are seen well at twenty feet or farther and not so well at twelve inches. One patient had a vision of 20/30 plus. The large black letters of the Snellen test card appeared blood red but at one half or one quarter of the distance the astigmatism was worse or increased. In other patients the color of the black letters was a shade of brown or yellow or green at a distance of fifteen feet, while the black letters never appeared black, but corrected the astigmatism when the distance was less than ten feet.

The facts observed on the production of astigmatism were modified by shifting. One patient looking directly at the first letter of a line of letters had no astigmatism at six feet. The patient was told that he would be asked to look at the last letter of the Snellen test card and he was able to do this, but before his eyes looked from the first letter to the last letter on the same line the astigmatism became very decided. Shifting from one letter to another at ten feet produced astigmatism. Astigmatism was temporary and by alternately shifting from the top period of the colon to the bottom period of the colon his vision improved. When he tried to see all parts of the colon simultaneously a strain resulted and a severe headache annoyed the patient very much. He found fault and said that he came to have his headaches cured, not to have them made worse.

To increase astigmatism is a very difficult thing. It requires much effort and with that effort to increase the astigmatism and to make the sight worse the patient complains that it is more difficult to increase the astigmatism and make the sight worse than it is to lessen the astigmatism and make the sight better. After many methods have been tried with much strain, it can be demonstrated that the production of a large amount of astigmatism is difficult. To lessen the astigmatism and improve the sight to normal is easy and can only be accomplished without effort.

The successful treatment and the cure of astigmatism without glasses is generally accompanied by so much strain that it is not always easy to make progress. It is very easy, however, to demonstrate that astigmatism is caused by a stare or strain and that rest or relaxation of the eyes will bring about a cure of astigmatism. The memory of familiar objects with the eyes closed is a great help in obtaining relaxation and lessening the amount of astigmatism. After the astigmatism is lessened by treatment, greater benefit can often be obtained by having the patient close his eyes and remember letters, music, and other mental pictures. Perfect memory means more perfect sight, because the greater the relaxation the quicker does the astigmatism disappear. It often happens that patients with astigmatism find it difficult to obtain relaxation, because they try to see too much of any one object at once and try to see letters, left side best, top best, bottom best, right side best (trying to see all best/equally clear at the same time, without shifting part to part).

The mere act of seeing one side of a letter at a time makes it easier to imagine the vision of each part of a letter.

One patient, when examined with the retinoscope, had a high degree of astigmatism. When he looked at the left side of some letter he could imagine the left side was straight, curved, or open. He imagined it straight with his eyes open and more or less clear; with his eyes closed the left side of the letter was remembered or imagined straight; the top was also imagined straight; the bottom was also imagined straight; and with the eyes open the left side, top, and bottom were imagined correctly. By alternately regarding each side of the letter with the eyes open and imagining these sides much better with the eyes closed, each side was imagined correctly. The patient was told to close his eyes and think of a letter, the left side straight, the top straight, the bottom straight, right side open. "What can you imagine the letter to be," he was asked. He answered: "It is an 'E'." The patient was drilled on a number of other letters with success. He was convinced that the imagination of one part of the letter improved the relaxation and enabled the patient to ignore the blurred outline of the letter regarded.

When the imagination improves the vision improves. One can at will plan to imagine a letter with the left side more or less straight and do it successfully after a number of times. Many failures occur because patients try to imagine the unknown letter by a strain. One of the most difficult cases to cure by relaxation methods responded favorably when his attention was called to the fact that he could, when the astigmatism was corrected, see a part of a letter better than a number of small letters. The letter was so imperfect that he could not distinguish the size, the color, or the form. **By explaining to him that he could see these blurred letters, one part of the letter at a time much better than he could see the whole of the letter at once,** he soon became able to see the letters perfectly in this way. When a pointer was placed in the neighborhood of the letter, the vision for that one

Shift back and forth, top and bottom on the colon. Blink. Eye movement = relaxation, clear vision. Practice on a fine print colon.

letter was improved more than for other letters of the same size and color. He could not see the left hand side correctly with his eyes open or closed. He was asked if he could imagine how the left side of the unknown letter would look if it had no blur. The imagination improved and with the improvement in the imagination the sight improved.

Some time ago there was printed in this magazine a description of a method of curing astigmatism which is far superior to all other methods. The patient was advised that there were white spaces between the lines of black letters and that these white spaces became whiter by alternately imagining them as white as possible with the eyes closed and then with the eyes open. The attention of the patient was called to the fact that one could imagine the bottoms of the letters resting upon the upper part of the white spaces, and when the letters were read a thin white line could be imagined going across the card from left to right. This thin white line was improved by the imagination of the line with the eyes alternately open and closed. When the imagination was successful in improving the thin white line, the black letters were imagined blacker and could usually be distinguished very quickly; but when the imagination of the white spaces was less perfect, the black letters could not usually be normally seen. In other words, the improvement in the vision for the black letters depended primarily upon the improvement of the whiteness of the thin white line. Of the two the thin white line was more important because one can imagine the whiteness of the thin white line much whiter relatively than the imagination can picture the blackness of the black letters.

The thin white line is directly under the bottom of the letters/sentence and is bright glowing white. The remaining area of the white space between the sentences is below the thin white line and is also bright white but less white than the thin white line.

Letters are frequently received by me, containing this very important question: "How can I remember black? It is impossible for me to remember black." One person wrote from the middle west that he could not remember or imagine black by central fixation. Whenever he tried he always failed and a number of friends of his also tried and they believed that it was impossible to remember or imagine a period that was anywhere near black. The man who complained had a high degree of astigmatism. This astigmatism was corrected by relaxation methods. His vision improved rapidly. By alternately practicing with his eyes open and with his eyes closed, his memory, his vision, and his imagination soon became normal.

Many people who try to see one period of a colon blacker than the other fail. If the patient can demonstrate that the cause of failure is a strain he soon learns that his failure is due *entirely* to strain. This strain is a mental strain. Many people fail because they lose their sight, memory, and imagination by an effort. **It is a benefit to people with imperfect sight to demonstrate that the cause is always an effort or trying to see.** It is astonishing to know that the memory of imperfect sight is so difficult and that it requires considerable time and patience to help a patient realize the facts. Most people believe that to do wrong is easy and are very much surprised when someone tells them the contrary and still more surprised when the facts are demonstrated.

Children eight years of age or younger have repeatedly demonstrated that imperfect sight, imperfect memory, and imperfect imagination are difficult.

When the largest letter of the Snellen test card is regarded, the blackness of it, the clearness of it, are so much better that people erroneously believe that the imagination of a large letter is much easier than the imagination of one half of the letter. When one half of a letter is covered, some people can imagine successfully that one half of the largest letter on the card is just as black, clear, and distinct as the same letter very much smaller. By continued practice the size of the letter or other object can be reduced to an area as small as the eye of a needle.

Perfect central fixation, using the exact center of the retina, fovea centralis, center of the visual field.

On one occasion a child ten years of age was brought to my office with normal eyes. The vision was tested and found to be normal. Her father said to her: "Can you tell that the largest letter on the test card is blacker than the very small letters." The child intelligently declared that the large letter was not blacker or clearer than the smaller letters. She could also make an effort sufficient to produce a considerable amount of astigmatism. Having normal vision, her control over her imagination was much better than that of patients with imperfect sight. The father then asked his daughter how she explained that she could see the small letters better than large ones. She replied that the reason she saw small letters better than large ones was because there was not so much to see.

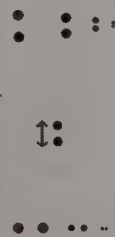

Having good sight the child could very readily produce a considerable amount of astigmatism by an effort of which she was conscious. Her father had much less control over his eyes than his daughter had. He could regard the card with good vision but his daughter could strain much more and produce a higher degree of astigmatism measured with the aid of the ophthalmometer. She was also able to imagine, when she saw a small letter at fifteen feet, that it was moving.

She was asked if she could stop the movement and when she did so a larger amount of astigmatism was demonstrated in her eyes than in those of her father. She was very much annoyed when she produced astigmatism because she said it gave her great pain. His central fixation was not so good as hers. It was difficult for him to imagine the top period of a colon best and the bottom worse or to imagine the bottom best and the top worse. He invariably saw both at the same time nearly equally well, while the daughter always saw one period at a time, the upper or lower, best.

A boy came to me to obtain glasses for the correction of astigmatism in each eye. With the right eye his vision was 10/20 or one half of the normal, but with the other eye he saw four times as much and the astigmatism was four times as great as in the other eye. This boy, when he covered over both closed eyes with the palm of one or both hands, instead of seeing black, saw everything else but black—gray, green, blue, yellow, and other colors—and his efforts to obtain black did not readily succeed. When he imagined imperfect sight he did not see black. When he imagined perfect sight and remembered perfectly the things which he had seen the astigmatism disappeared and he was able to remember, imagine, or see perfect black.

Many facts of considerable value were observed. When the boy imagined a large object while palming, his astigmatism was slight when he opened his eyes, but when he remembered letters or other objects with imperfect sight with the left eye open his vision became worse. Perfect imagination enabled him to produce a greater amount of astigmatism than he was able to do when the vision was poor. When the right eye had more perfect imagination he became able to imagine more perfect vision and in addition he could imagine sight that was more imperfect. With a good imagination he had more perfect sight and at the same time remembered or imagined a greater degree of astigmatism than when his sight was poor. He demonstrated that when his mind was more under his control he could remember or imagine a larger amount of astigmatism. When his sight was good the mental control of his vision was improved. When his eyes were closed he could remember or imagine more perfect black than he could remember or imagine when his eyes were open. He demonstrated that he could produce a larger amount of astigmatism or a lesser amount of astigmatism as he desired because, his mind being under his control, he could remember things or imagine things better than he could when his mind

Look at, see one dot  
clearest at a time in the  
center of the visual field.  
Shift top and bottom, left  
and right on the black  
dots seeing one dot at a  
time clearest as the center  
of the visual field moves  
dot to dot with the eyes.  
Each dot the central field  
moves onto becomes the  
clearest dot. Shift part to  
part on one dot and see  
one small part of the dot  
clearest at a time in the  
center of the visual field.  
Practice on fine print dots.

was not under his control. The retinoscope was a great help in controlling the astigmatism. With its aid the amount of the astigmatism could be determined.

## Two Cases of Myopia

By EMILY A. BATES

A LITTLE girl, aged seven, came to Dr. Bates for the first time for treatment. She had a high degree of myopia with astigmatism and had worn glasses for a few years. According to her mother's statement she was a very nervous child, due to eyestrain. The vision in each eye was 15/40 minus. The usual treatment was given the child, first having her close her eyes to rest them. Then with the aid of the **long swing**, the **variable swing**, and the **sway** of the body, which was a rest to her, her vision improved to 15/20 minus. Dr. Bates explained to the mother that it would be necessary for her to have daily treatment for at least two weeks in order to bring about a satisfactory improvement in her sight. The mother explained that she was taking a long trip with her family and could not at that time remain longer than a day.

On her way west she stopped at a place where we had a competent student who treated the child successfully and gave her a temporary improvement in her sight as Dr. Bates did. The mother then went west where her child was placed under the care of a person who has only a slight knowledge of what the Bates Method really is. As the result of the improper treatment given this child, in one year's time her vision was lowered from 15/40 to 15/100 in each eye. Dr. Bates was much concerned about the lowering of her vision and found out that diathermy (A form of physical therapy using the therapeutic generation of local heat in body tissues by high-frequency electromagnetic radiation, electric currents, or ultrasonic waves.) and other appliances were given as treatment for the relief of eye strain. The treatment produced more strain and the myopia became worse. When such patients return to Dr. Bates they are extremely hard to treat and if I can possibly help it I try to dodge such cases unless I am promised a reasonable length of time in which to benefit the patient.

After the Doctor saw the child again, Miss Katherine Hayes, our secretary and assistant, was directed to treat the child, which she did with satisfactory results. On October 19th, the day the patient returned for more help, her vision was 15/100. On October 22nd her vision had improved to 15/15.

On September 12th, 1929, the mother returned again with her child for more treatment. It was found that the vision in both eyes was the same and by practice she improved to 15/10. During her absence between September 12th and October 26th, her vision gradually became better because the mother had kept in constant communication with Dr. Bates. The advice which she received for home treatment for her child helped. With but a few exceptions results are usually obtained if the mother keeps up the constant practice for her child every day.

On September 14th, the mother again left for her home in the west and again returned early in December for a check up. It was found that Betty had carried out the instructions given her for daily practice at home or wherever she might be, with the result that she no longer made an effort to read the letters of the various test cards placed before her, which was something she always did and had to be reminded constantly not to do. She found out all by herself that the harder she tried to read the letters of the cards the more her vision blurred. Shifting from a near object to the test card as she was reading avoided any effort to see better. When she noticed that the black letters of the white test card became blacker if she did not look too long at them, she enjoyed the treatment much more. The card which she had moved near her was placed at ten feet and she began to strain her eyes to see, causing a frown and a wrinkling of her forehead, which the mother herself corrected before I had a chance to do so myself. I know that the mother's efforts to help me with the child brought about a better vision which remained with her most of the time.

The next day Betty did better, improving two lines on a strange test card. On a sign about fifty feet to the left of our office windows were letters which she could not read distinctly at first, but during the treatment she became able to read all of the sign letters which were much smaller at the bottom of the sign than at the top. Shifting from this sign to the test card in the room again improved her vision for another line, namely 10/15.

The next day, having sunshine in the room, we gave her the sun treatment for about twenty minutes. Small test card letters seen by the normal eye at four feet she was able to read nine inches farther away by shifting from the white spaces to the type. Then all the test cards which were used in our office were placed at a distance of fifteen feet and she read each one of them through to the bottom line without a mistake. Her mother and I decided to test her memory for these various test card letters by having her close her eyes and read from memory. She was able to do this successfully with two of the test cards but she had not memorized the others, even though she had practiced with them while she was in our office. This proved to the mother that the memory of the known letters with her eyes closed helped her to read all the other test cards when her eyes were open and to read them at more than the normal distance. The nervous twitch of her body which was in evidence always toward the end of her treatment and during her last few treatments had entirely disappeared. I believe that Betty is entirely cured now.

Betty's brother Bobby, aged twelve, had never worn glasses although he has for many years had myopia or short sight. His vision in the right eye was 10/50 and with some help from me he was able to read some of the ten line letters of the card with his left eye. He explained that the bottom line of the test card looked as though each line had a tail to it, and that all the P's looked like T's and the F's much like a P, only distorted. He could not raise his head sufficiently to read the test card but always while reading he would lower his head so that his chin almost touched his chest. This produced a strain which Bobby did not at first believe was the cause of his trouble. He thought that it was perfectly right for him to lower his head in order to see better.

I did something to Bobby which I rarely care to do with most patients, although it is a good demonstration to the patient that strain causes the lowering of sight. Dr. Bates is successful in having patients demonstrate for themselves that producing discomfort from straining helps them to overcome the trouble. In most cases I have hesitated to try this because it affects me personally and causes me to strain so that sometimes I cannot go on with the treatment. Bobby was so enthusiastic about wanting to be cured that he was perfectly willing to have me demonstrate anything that he did which was wrong so that he could cure it.

Bobby had the mind of a boy sixteen or seventeen years of age instead of a boy of twelve, and he carried out my instructions very much like our West Point cadets or the boys who are ready to enter Annapolis. We have had many from both academies and so far we have not found one of them difficult to treat, no matter how severe their eyestrain might be. Dr. Bates thinks that discipline and knowing what it means to pay attention makes this type of patient easy to treat and to benefit. I think little Bobby is headed for either one of these places for he spoke about it every time he came.

He was encouraged to do the long swing, not paying any attention to stationary objects in the room. Occasionally I had to remind

him to keep his chin up like a soldier, which always spurred him on. I believe also that his sister being in the room and watching his treatment helped me in treating him also. She looks upon him very much like a hero and is proud of everything good that he does. Just a little sound of approval from her made him show off a wee bit, which made it amusing to me. His vision improved in less than a half hour's time to 12/10, reading with both eyes together at first. Having no sunshine while treating him I gave him the thermo-lite for half an hour. Then I tested his right eye, having his left eye covered, and found that he had improved to 10/15 from 10/50 in less than one hour's time and not once had he lowered his head to read better.

The next day we had sunshine and while Bobby resented the strong light of the sun at first as the sun glass was used on his closed eyelids, he soon became accustomed to it and liked it, asking for more. After the sunlight treatment the vision of the right eye improved that day to 10/10. The next day we did some mental arithmetic while he was taking the sun treatment and found that that was not so good. Trying two things at one time was not helpful to Bobby. The sun glass was then used and after half an hour of sun treatment he palmed and then we did some mental arithmetic. He visualized the numerals as they were given to him and as quickly as I mentioned the figures he gave the answers correctly, not once making a mistake. Again his right eye was tested with a strange card and his vision had improved to 12/10.

I drew his attention then to the sign outside of our window and then to a more distant sign about five hundred feet away and he became able to read all of the sign at that distance with both eyes together. Then I turned him around, facing another strange test card and he read the bottom line, the smallest letters of the card, at fourteen feet two inches.

This boy before coming to me had had diathermy and other treatment, which perhaps improved his vision temporarily but did not last. He explained to me that the electric treatment which was given him for the improvement of myopia caused a nervous affliction of the body. The advice given Bobby to keep up the good vision obtained through our treatment was to play ball, watch the ball as he threw it to the other player and then blink and sway a little bit as the ball was thrown back to him. I gave him a little demonstration of this in the office, which he enjoyed. I told him to play other games where only two objects were used, one a ball and the other a goal or certain point where the ball should be thrown. **The old fashioned horse-shoe game is not only relaxing but it gives the patient an opportunity to practice shifting.**

Betty and Bobby could not be treated exactly alike because their minds were not alike. Each had to be studied carefully before the treatment could be successfully given. If the doctor or student does not carry out this idea the patient has little chance to be relieved entirely of eyestrain.

Playing horseshoes. Eyes follow, shift on the horseshoe as it is thrown through the air, and on the target. Improves eye movement, central fixation. Juggling, baseball... many sports keep the vision clear.

## Notice

Dr. Bates, as well as the Central Fixation Publishing Company, has been receiving a number of letters recently from people who have been unsuccessfully treated by practitioners who have not taken Dr. Bates' course of instruction and do not understand the Bates Method thoroughly.

Dr. Bates gives a course of instruction to doctors, teachers, nurses, and others who wish to practice his method professionally. At the end of the course the student receives a certificate authorizing him to help others by the Bates Method. Those wishing further particulars may obtain them by writing direct to Dr. Bates at 18 East 48th Street, New York City.

+ We wish to inform our subscribers that the Better Eyesight Magazine will be discontinued after the June, 1930, issue. This will enable Dr. Bates and Mrs. Bates to devote more time to the writing of new books on treatment alone for which there has been a very great demand during the past year. Subscriptions for the remaining months, however, are being received. +

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

FEBRUARY, 1930

See Things Moving

When the sight is perfect the subject is able to observe that all objects regarded appear to be moving. A letter seen at the near point or at the distance appears to move slightly in various directions. The pavement comes toward one in walking, and the houses appear to move in a direction opposite to one's own. In reading, the page appears to move in a direction opposite to that of the eye. If one tries to imagine things stationary, the vision is at once lowered and discomfort and pain may be produced, not only in the eyes and head, but in other parts of the body.

This movement is usually so slight that it is seldom noticed till the attention is called to it, but it may be so conspicuous as to be plainly observable even to persons with markedly imperfect sight.

**+If such persons, for instance, hold the hand within six inches of the face and turn the head and eyes rapidly from side to side, the hand will be seen to move in a direction opposite to that of the eyes. If it does not move, it will be found that the patient is straining to see it in the eccentric field. By observing this movement it becomes possible to see or imagine a less conspicuous movement, and thus the patient may gradually become able to observe a slight movement in every object regarded. Some persons with imperfect sight have been cured simply by imagining that they always see things moving.**

See opposite movement

The world moves. Let it move. All objects move if you let them. Do not interfere with this movement, or try to stop it. This cannot be done without an effort which impairs the efficiency of the eye and mind.

WHEN one imagines stationary objects to be moving in the same or opposite direction to the movement of the head or eyes when both heels are resting on the floor, it is called the sway. When both heels are lifted from the floor it is not called the sway, but the swing. The apparent movement of stationary objects may be horizontal, vertical, or at any angle. The sway is a very valuable thing to use because it promotes relaxation or rest much better than many other methods. In fact, so general is this conclusion that I always try to have every patient practice the sway immediately upon starting treatment.

The sway may be practiced rapidly or slowly and with a wide or a narrow motion. When the sway is practiced, distant objects are covered more or less completely, which explains why rest is obtained. When the sway is used properly, all stationary objects regarded appear to be moving. Whether the sway is short or long, if practiced properly, the vision is usually improved after other methods have failed. Distant objects move in the same direction the eyes, head/body move to and close objects move in the opposite direction.

In reality, distant objects appear to move opposite but the movement is so slow that they appear to move opposite especially when there is a close object in front of the distant object.

Patients suffering from insomnia are much benefited by the sway. They soon become able to sleep at night and a maximum amount of rest is obtained. Most people with imperfect sight have a constant strain and tension of nearly all the muscles of the body. The nerves are also under a strain and their efficiency is frequently lost. By practicing the sway properly, fatigue is relieved as well as pain, dizziness, and other symptoms. The sway always brings about a relief from the effort of trying to see, staring, or concentration.

The normal eye needs relaxation or rest; it does not always have normal sight. When it is at rest it always has normal sight. Things which are done by the patient to improve the sight do not always succeed. There are many ways of improving the sight by the sway, provided it is practiced correctly. I remember a patient who came to me about ten years ago, who went to London to obtain relief from a severe and constant pain in her eyes and head. She could obtain no relief in London and was advised to come to me. When I saw her, she was in a pitiful condition from the constant pain which was often present every hour during the day and at night. Many people suffer from pain unconsciously during the night and the characteristic symptom is pain the first thing in the morning as soon as the patient becomes conscious.

(Trying to see all areas of the visual field at the same time, central and peripheral field, equally clear. Placing the object of visual attention in the peripheral field, moving the eyes and head/face in opposite directions. These are all types of diffusion, eccentric fixation, the opposite of central fixation.)

This patient had eccentric fixation simultaneously practiced unconsciously most of the time when the patient was conscious. She was examined and shown that when she practiced the sway with her eyes moving in one direction and her head in the opposite direction, the result was a very bad strain which was very painful. This is another illustration of the fact that many things which can be practiced properly can also be practiced improperly. I do not know of a pain which is more severe than that which happens when the eyes are moved in one direction while the body moves in the opposite direction. This method of practicing the sway is to be condemned because of its bad results in producing pain and other symptoms. When this patient practiced the sway properly, her pain disappeared.

A physician wrote to me about his ten-year old son. The vision of the left eye was good, but the vision of the right eye was very poor because the **center of sight was gone**. As a result of an injury his central vision was lost and one could see that the retina was destroyed, forming a disk of about one quarter of the size of the papilla of the optic nerve. When examined with the ophthalmoscope it was found that the center of sight had been destroyed over an area of one eighth of the size of the papilla of the optic nerve. The boy was treated for about six months and much to my surprise his vision improved and became normal in the injured eye by the practice of the sway, without any other treatment.

A third patient was treated for central **scotoma**. The vision of the left eye was normal but that of the right eye was very poor. The principal cause of her defective sight in the right eye was inflammation of the retina and choroid. She had called on many physicians and most of them told her very positively that she would become blind in the right eye and later on blind in the left eye. When she came to see me she was almost frantic with apprehension and with tears in her eyes she begged me to help her. I was having very good results with the sway and knowing very well that the sway could do her no injury I did not hesitate in having her practice it. In two weeks she was cured and had perfect sight in each eye.

About fifteen years ago an elderly woman was ushered into my office. It seems that she had traveled all over the country consulting prominent ophthalmologists, but had had no success in obtaining relief. She gave a history of constant pain, constant fatigue, inability to sleep at night, and many other symptoms which she could not describe. She told me that if she could only find out what was wrong with her, she might by some possibility obtain relief. She had so many and varied symptoms of discomfort that she could not discover the cause of her trouble. Every doctor who examined her admitted that he did not know what was wrong. Her sight for distant vision was good, and although over fifty years of age she had no presbyopia and could read diamond type at six inches rapidly, easily, without discomfort. In fact there were times when she could read all night without fatigue, but suffered from some discomfort that she could not describe. In other words she did not know what was the matter with herself.

Blindness was expected by some doctors in the course of two or three years. Some other doctors believed that she could live for only one year without becoming totally blind. I told the lady that I did not know what was the matter with her either, but I believed that she could be cured even without any diagnosis being made, or without discovering the cause of her trouble. Then I said to the lady: "Place your finger about opposite the lower part of the chin and then move your head and eyes from side to side. When you do it properly, you can imagine the finger to be moving and there will come to you a relief from all the various troubles from which you suffer." She started to do as I suggested and by watching her very closely it was quite easy to keep her head and eyes moving as they should. This sway was a great relief to all the troubles of which the patient complained and it gave complete relief to many discomforts from which she had suffered.

A woman from Washington came for treatment of **disease and blindness of the central part of the right eye**. The left eye was nearly normal, with good vision. She had been told that the right eye was inflamed to such an extent that it was probable that it would require a long time, many months, before the symptoms were relieved. When she moved her head and eyes a short distance from side to side, the test card five feet away and other stationary objects appeared to move in the opposite direction. But when her

Sway left and right, up and down, diagonally, forward and backward and see opposite movement of objects in the visual field. Relax and blink.

right eye moved to the left while her head was moved in the opposite direction, pain and imperfect sight were produced. The sway was practiced daily and in a few weeks her vision became normal in both eyes.

## Why Patients Fail

By EMILY A. BATES

ON PAGE 15 of my book, "Stories From The Clinic" I have suggestions which if read by patients would help them to do the right thing while taking treatment for their eyes. Suggestion Number One reads as follows: "If the vision of the patient is improved under the care of the doctor, and the patient neglects to practice, when he leaves the office, what he is told to do at home, the treatment has been of no benefit whatever. The improved vision was only temporary. Faithful practice permanently improves the sight to normal." This does not mean one must work hours at a time, practicing the advice given for the improvement of sight, but it does mean that he should devote as much time as possible to practice and not make hard work of it.

We have repeated in a great number of articles that it only takes a minute to test the sight with a test card and if the patient practices a few minutes in the morning, it will help a great deal during the day. If at any time during the day, a strain is produced for some reason or another, the memory of one of the test card letters which was seen perfectly usually relieves all symptoms of strain and discomfort. Sometimes relief is only for a minute or two, but if the patient can remind himself to do this several times a day, the improved vision remains for a long time. Even with errors of refraction and organic diseases, the symptoms are lessened by the memory of a known letter or a known object seen clearly.

Most people, even those who have no trouble with their eyes, feel relieved from strain and discomfort of other parts of the body by the **memory of some pleasant scenery or beautiful colors which are remembered without effort**. There are certain shades of color which do produce mental strain and at the same time cause a lowering of the vision. Green, no matter what shade of green it may be, is usually a rest and relaxation to the mind and eyes. Personally I can relax immediately if I am suffering from mental strain, which is frequently the case, by thinking of a Nile green shade or any object of that color.

Perhaps I can make myself understood better by telling about a case of hypermetropia in a woman, fifty-one years old, whose sight was poor for the near point as well as for the distance. She suffered from a great deal of pain and discomfort in her eyes at times. I tested her sight for colors, using different shades of yarn which I held exposed to her view at a point about ten feet from her eyes. She wore a light colored dress which had the combined shades of brown, tan, and yellow. She mentioned the different shades of yarn as I held them up for her to see and when I placed before her a shade of black yarn, she said: "Isn't it funny that I don't care for black especially."

Here was a problem. For years the doctor had helped patients by the memory of black, usually remembered by the patient with his eyes closed. For some time we had made good progress in benefiting patients' eyes by having them remember colors with their eyes closed and imagining one period blacker than another and then vice versa. I had planned to treat this woman in this way, using a colon as an object. I immediately removed that thought from my mind and planned to help her in some other way. Some of our test cards have red and green lines which are sometimes a great help in improving the patient's vision for the smaller letters at a distance of ten feet or further. Testing her with these cards and improving her sight with the memory of the green colored line not only helped the patient's eyes, but also relieved the symptoms of pain and discomfort that she had had for some time.

At this patient's second treatment she gave me a report of the progress she had made while practicing at home. She enjoyed drawing, which I advised her to continue to do, and then for pastime while she was practicing she used different colored crayons for the drawings. She brought the drawings with her, and we thought they were beautifully done. At her second visit she wore a black gown, and all through her treatment I had to listen patiently for twenty minutes to her account of the sadness she had had through her life, of the care that some of the members of her family were to her, and of how hard it was for her to remain cheerful.

I tested her sight and found it about the same as it was before I treated her in the beginning. I made the room unusually bright by using the thermolite as well as the ceiling lights which we have in our office. I then started testing her sight for colors at fifteen feet, using the yarns again and while it took a little longer to have her mention the colors correctly, I did succeed finally in making her forget about her family troubles and worries. I wanted to be sure that I was right about the change of temperament because of her black gown, so mentioned it to her and told her to remember black while palming. Instead of being quiet she talked incessantly of her pain and the operations that she had had from time to time and the only way I could quiet her was to tell her that I had several of them myself but that I did not worry about them any longer. I asked her if she had read Irvin Cobb's book on operations and told her some of the funny stories which were in his little book. She soon found out that I did not care to discuss operations.

What I want to explain at this point is that color has a great deal to do with mind strain. I believe that people are much happier now that brighter color combinations are being used in our homes.

Modern teachers state that a dislike for certain colors can be caused by left and right brain hemisphere imbalance, one hemisphere or part of the brain not as active as the other hemisphere/areas of the brain. A unpleasant past or present experience that is associated with a certain color can also cause dislike for the color. Removing the negative thoughts, emotions associated with the color enables the person to enjoy the color. A lady that disliked the color yellow had worked in a factory where most of the toy items were yellow. She was abused by employees at the factory. After practicing deep relaxation, left and right brain hemisphere activation and integration exercises, color treatment, replacing the negative thoughts, emotions associated with the factory with positive ones, finding a better job and associating the color yellow with the shiny, bright golden color of the pollen in the center of a dandelion in the sunlight; she came to like and generative a positive feeling when seeing the color yellow.

Exposing the person to a color they dislike, in a positive way can activate the brain hemisphere/area of the brain that is suppressed for equal activation and integration of the left and right hemispheres and bring to the surface unpleasant thought emotions associated with the color, enabling their release and replacement with positive thought, emotions and clear vision.

Dr. Bates and Emily's method of using colored yarn, crayons, remembering, imagining colors is an original version of modern Natural Vision Improvement Color Treatment.

Sometime ago I had a patient over sixty years of age who had double vision almost all the time. Large objects were seen single but small objects were always seen double. Test card reading was not easy for this patient so I had to conceal every letter on the test card with the exception of one. After he mentioned that one correctly it was covered over and another letter was exposed to view. If he looked at a card longer than a fraction of a second, without turning his head either to the right or to the left, he would

The color green relaxes the mind, eyes. Carry a green emerald, rhinestone and shift on it close to the eyes. Relaxing and improves close and distant vision.

always see the letter double. Shifting quickly from a letter to the blank wall on either side of our room helped him to see the letter single and not double when he looked at it again. He was told to do the long shift when he practiced with the card and to shift only an inch or two to the right or to the left whenever he was looking at anything else either up close or at the distance.

This patient did not come regularly for treatment, but he came off and on for about a year, when he was finally cured of his double vision. A variety of flowers which were growing near his home helped when he was outdoors where he practiced the sway of the body, moving from left to right and always remembering to blink. As he did this he saw the flowers as they were, instead of seeing them double which had been his trouble for many years.

Tension in/on the muscles, nerves, vertebrae in the neck, can disrupt eye muscle, eye, brain, ear function resulting in unclear vision, double vision... Relaxation, movement of the neck removes the blur and double vision.

At the present time we have a little child taking treatment for **blindness** in one eye. Both eyes have **cataract**, but the left eye also has **scar tissue in the cornea**. Apparently there was not any sight in the left eye because there was no red reflex seen when the ophthalmoscope was used. Toys of different colors were placed before her and as she mentioned the names of each of the animals they were placed on the floor at a distance of five feet or farther. At this distance she sometimes made a mistake in naming the animal. The harder she tried to see the toy at the distance, the more blind she became.

I taught her the long swing, having her shorten the swing to a short sway of the body and advising her to blink as she swayed. She then became able to name the animals correctly as they were placed a few feet farther, but only when she mentioned the color of the toy first. Just by blinking as she swayed she remembered for part of a minute the color of the animal she was asked to mention. When she was not reminded to blink or to keep up the sway she made an error in naming the animal.

It is good to have someone in the room while such patients are under treatment, especially if they are to help the patient away from our office. They can understand very readily why some patients fail when they stare even for only a fraction of a second. It is necessary constantly to remind the patient that in order to bring about a permanent benefit, he must not fail to do as he is advised when away from the office.

Failure to remember a color with the eyes closed lowers the vision and causes the sight to become imperfect. Failure to take time enough to practice or to read the chart every day is a mistake and causes failure. Daily practice counts, no matter how little time one has. After all, the Bates Method is eye education. To miss one day in the cure of the eyes when they need attention for the improvement of sight is much like failure to study a certain lesson each day in school, or to attend to any work which requires daily study or practice. In most cases when improvement is made in the sight by a teacher of eye education it is only a temporary one, but it is enough to encourage the patient to keep on with the practice until the sight becomes normal. Patients who are cured in one visit are those who can retain the relaxation and rest which is the foundation of the method.

Eye diseases such as atrophy of the optic nerve, iritis, glaucoma, and cataract, are always benefited when the patient does not neglect to practice every day. The sight of patients who suffer from organic diseases is usually very poor. All organic diseases become less when the sight improves by relaxation and rest.

## Case Report

(Editor's Note—We believe that the following letter will prove of interest to our readers. Dr. Rath, of 115 Francis St., Jackson, Mich., has recently completed a course of instruction and, as the following report of a case indicates, he is already doing splendid work.)

Dear Dr. and Mrs. Bates:

It just occurred to me that you might be interested to know how I am coming on with the little boy that had so many doctors. We call him "**the little boy of the forty doctors.**" His name is Stanley and when Stanley's father first came to me he had just about given up hope. He remarked that Stanley lived in a world all his own. He did not play much with other boys because he could not see. Stanley spent most of his time with his mother when not in school.

The school physician placed Stanley in the "Eye Saving School." They use great large letters in all their books.

Stanley's father was not satisfied with his last doctor and really did not know what to do. He talked to the superintendent at the factory where he works about it, and he sent him to us for advice. Having just returned from No. 18 E. 48th Street, full of inspiration, I told him to bring the boy down and let me look at him. He has now been to see me just ten times. He is now reading the bottom line on the C chart, the white card with black letters, 10/10 vision, and the bottom line on the little hand chart. He does not do this very rapidly, but he is doing it.

I wish you could see him do the "long swing." He does this with a grace that is charming.

The last time they came, his mother told me that Stanley's complexion had actually changed since he began the "Bates System." The neighbors are noticing the great change in the lad, and the mother and father want to send him to the regular school. I don't know how we will come out in this respect as they likely will not believe he can see well enough. I had him bring with him a book that they use in the regular school, and he reads it without the least difficulty. He plays with the other boys, and he tells me, in playing ball, he not only sees it, but he can hit it too.

Every time Stanley comes to see me he is just a little better. When I first saw him he was downcast; now he is happy and buoyant.

I am doing wonderfully well with the "Bates System" and if it were not for making a tedious and long letter I would write you more.

With best wishes,

Sincerely,  
(Signed) John A. Rath.

P.S.—I neglected to state that when Stanley was first brought to me he was seeing all colors of the rainbow, especially green. This has all ceased.

Dr. Bates, as well as the Central Fixation Publishing Company, has been receiving a number of letters recently from people who have been unsuccessfully treated by practitioners who have not taken Dr. Bates' course of instruction and do not understand the Bates Method thoroughly.

Dr. Bates gives a course of instruction to doctors, teachers, nurses, and others who wish to practice his method professionally. At the end of the course the student receives a certificate authorizing him to help others by the Bates Method. Those wishing further particulars may obtain them by writing direct to Dr. Bates at 18 East 48th Street, New York City.

We wish to inform our subscribers that the Better Eyesight Magazine will be discontinued after the June, 1930, issue. This will enable Dr. Bates and Mrs. Bates to devote more time to the writing of new books on treatment alone for which there has been a very great demand during the past year. Subscriptions for the remaining months, however, are being received. We request that all those who desire to be notified upon the publication of new books kindly send us their names and addresses, which will be kept on file.

## Announcement

Dr. Bates takes pleasure in announcing that the following have recently completed courses of instruction under him and he highly recommends them to anyone desiring their services:

Miss Clara M. Brewster,  
Studio 6, Aquila Court,  
Omaha, Nebraska.

Mr. Fred Baechtold,  
633 Hudson Ave.,  
West New York, New Jersey.

Mr. Baechtold will be pleased to visit those patients who desire to receive treatment at home. Appointments can be arranged by telephoning him at Palisade 7735.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MARCH, 1930

### How Not to Concentrate

To remember the letter O of diamond type continuously and within effort proceed as follows:

+Imagine a little black spot on the right-hand side of the O blacker than the rest of the letter; then imagine a similar spot on the left-hand side.

+ Shift the attention from the right-hand spot to the left, and observe that every time you think of (look at) the left spot the O appears to move to the right, and every time you think of (look at) the right one it appears to move to the left. This motion, when the shifting is done properly, is very short, less than the width of the letter. Later you may become able to imagine the O without conscious shifting and swinging, but whenever the attention is directed to the matter these things will be noticed.

+Now do the same with a letter on the test card. If the shifting is normal, it will be noted that the letter can be regarded indefinitely, and that it appears to have a slight motion.

To demonstrate that the attempt to concentrate spoils the memory, or imagination, and the vision:

+Try to think continuously of a spot on one part of an imagined letter. The spot and the whole letter will soon disappear.

+Or try to imagine two or more spots, or the whole letter, equally black and distinct at one time. This will be found to be even more difficult.

+Do the same with a letter on the test card. The results will be the same.

Staring = Trying to see/look at all parts of a object at once, without shifting part to part, (staring, not moving the eyes) or: Looking at only one part without shifting to other parts (another type of staring) causes strain and blur.

Imagine a black dot on the left and right sides of a fine print letter O. Shift back and forth, left and right on the dots and see the O move in the opposite direction the eyes move to. A very short movement, less than the width of the letter. Shift right, the O moves left. Shift left, the O moves right.

## Squint and Amblyopia: Their Cure

By W. H. BATES, M.D.

620

SQUINT, or strabismus, is that condition of the eyes in which both eyes are not directed to the same point at the same time. One eye may turn out more or less persistently while the other is normal (divergent squint), or it may turn in (convergent squint), or it may look too high or too low while deviating at the same time in an outward or inward direction (vertical squint). Sometimes these conditions change from one eye to another (alternating squint), and sometimes the character of the squint changes in the same eye, divergent squint becoming convergent and vice versa. Sometimes the patient is conscious of seeing two images of the object regarded, and sometimes he is not. Usually there is a lowering of vision in the deviating eye which cannot be improved by glasses, and for which no apparent or sufficient cause can be found. This condition is known as *amblyopia* and is supposed to be incurable after a very early age, even though the squint may be corrected.

Operations, which are now seldom advised, are admitted to be a gamble. According to Fuchs,<sup>1</sup> "their results are as a rule simply cosmetic. The sight of the squinting eye is not influenced by the operation, and only in a few instances is even binocular vision restored." This is an understatement rather than the reverse, for a desirable cosmetic effect cannot be counted upon, and in not a few cases the condition is made worse. Sometimes the affected eye becomes straight and remains straight permanently, but often, after it has remained straight for a shorter or a longer time, it suddenly turns in the opposite direction.

I myself have had both successes and failures from operations. In one case the eyes not only became straight, but binocular single vision—that is, the power of fusing the two visual images into one—was restored, and when I last saw the patient, thirty years after the operation, there had been no change in these conditions. Yet when I reported to the ophthalmological section of the New York Academy of Medicine that I had cut away a quarter of an inch from the tendon of the internal rectus of each eye, the members were unanimous in their opinion that the eyes would certainly turn in the opposite direction in a very short time. In other cases the eyes, after remaining straight for a time, have reverted to their old condition, or turned in the opposite direction. The latter happened once after an apparently perfect result, including the restoration of binocular single vision, which had been permanent for five years. The consequent deformity was terrible. Sometimes I tried to undo the harm resulting from operations, my own and those of others, but invariably I failed.

Glasses, prescribed on the theory that the existence of errors of refraction is responsible for the failure of the two eyes to act together, sometimes appear to do good; but exceptions are numerous, and in many cases they fail even to prevent the condition from becoming steadily worse.

The fusion training of Worth is not believed to be of much use after the age of five or six, and often fails even then, in which case Worth recommends operations.

Fortunately for the victims of this distressing condition, **their eyes often become straight spontaneously**, regardless of what is or is not done to them. More rarely the vision of the squinting eye is restored. If the sight of the good eye is destroyed, the amblyopic eye is very likely to recover normal vision, often in an incredibly short space of time. In spite of the fact that the textbooks agree in assuring us that amblyopia is incurable, many cases of the latter class are on record.

The fact is that both squint and amblyopia, like errors of refraction, are functional troubles, originating entirely in the mind. Both can be produced in normal eyes by a strain to see, and both are immediately relieved when the patient looks at a blank surface and remembers something perfectly. A permanent cure is a mere matter of making this temporary relaxation permanent.

Permanent relaxation can be obtained by any of the methods used in the cure of errors of refraction, but in the case of young children who do not know their letters these methods have to be modified. Such children can be **cured by encouraging them to use their eyes on any small objects that interest them**. There are many ways in which this can be done, and it is important to devise a variety of means so that the child will not weary of them. For the same reason the presence of other children is at times desirable. There must be no compulsion and no harshness, for as soon as any method ceases to be pleasant it ceases to be beneficial.

The needle, the brush, the pencil, kindergarten and Montessori material, picture books, playing cards, etc., may all be utilized for purposes of eye training. At first it will be necessary to use rather large objects and forms, but as the sight improves the size must be reduced. A child may begin to sew, for instance, with a coarse needle and thread, and will naturally take large stitches. As its sight improves a finer needle should be provided, and the stitches will naturally be smaller. Painting the openings of letters in different colors is an excellent practice, and as the sight improves the size of the letters can be reduced. Map drawing and the study of maps is a good thing, and can be easily adapted to the state of the vision. With a map of the United States a child can begin by picking out all the states of a particular color, and as its sight improves it can pick out the rivers and cities. In drawing maps it can proceed in the same way, beginning with the outlines of countries or states, and with improved vision putting in the details. A paper covered with spots in various colors is another useful thing, as the child gets much amusement and benefit from picking out all the spots of the same color. With improved vision the size of the spots can be reduced and their number increased.

Many interesting games can be devised with playing cards. "Slap Jack" is a good one, as it awakens intense interest and great quickness of vision is required to slap the Jack with the hand the moment its face appears on the table.

These ideas are only suggestions, and any intelligent parent will be able to add to them.

## Case Reports

### CASE 1

Several years ago, a woman came to me with her daughter, aged ten. The child was suffering from well marked alternate internal squint. Sometimes the right eye would turn in so far that the pupil was covered over by the inner corner of the lids. At other times, the child was observed to be afflicted with internal squint of the left eye. Her mother told me that they had been to several large cities, including the capitols of Europe, where she had hoped to obtain a cure for her daughter's squint.

The child was a great reader and had read many books. Her memory was unusually good. She also had a very good imagination. She could read the ten line of the Snellen test card at more than twenty feet in a good light. When the light was poor and her vision was tested with the aid of a strange card, she was able to imagine correctly each of the four sides of any letter. For example, the letter "E" was the fourth letter on the fifth line of the test card. When the test card was placed thirty feet away in a poor light, she was unable to distinguish the letter as a whole.

After closing her eyes and covering them with the palms of both hands (palming), she imagined the left side of the "E" to be straight. When she imagined the left side of the "E" was curved or open, she strained. She imagined the top straight, and the bottom straight, and the right side open, which was, of course, correct. When any of the sides were imagined wrong, she always strained and was more or less uncomfortable.

She was then asked to imagine the fourth letter on the sixth line. She was still practicing palming. She was able to imagine the left side of the unknown letter to be straight, the top straight, the bottom open, and the right side open. She imagined that the letter was an "F" and was correct.

She was then tested with diamond type at about ten feet from her eyes, a distance at which it was impossible for her to read the letters. She was then told to palm. While palming, she was asked to imagine the first letter of the fourth word, on the fifteenth line of the diamond type. With her eyes closed and covered, she was able, without effort, by imagining each of the four sides correctly to demonstrate a letter "M." She imagined this letter so perfectly that she was able also to imagine other letters of the same word correctly. The exercise of her imagination was continued for an hour during which time she imagined correctly a number of lines of the diamond type. The result was very gratifying, because the squint disappeared in both eyes and the relief was manifest two days later.

The mother supervised the imagination of the fine print for half an hour daily for many days and weeks, with the result that at the end of six months, the child's eyes were still straight. The treatment was then discontinued, and at the end of five years, her eyes still remained straight.

### CASE 2

A girl, aged fourteen, had vision of the right eye of 3/200 while that of the left eye was 20/10. When she was two years old the tendon of the muscle which turned the right eye inwards was cut. The result was variable. Sometimes the eye turned in as before, but there were periods when the right eye was straight. Relaxation methods were employed daily with success and the squint became less when the vision improved.

The method which helped the most was to improve the vision of the amblyopic eye by remembering or imagining perfect sight of one letter of 20/10 with the eyes alternately closed and open. The vision of the right eye improved until it became 20/10. The patient was also encouraged to imagine fine print six inches from the right eye. When she succeeded in improving her vision for twenty feet and later her ability to read fine print at six inches, the squint disappeared. Both eyes focused on one point at the same time.

Central fixation or seeing best ■ letter or other object regarded (in the center of the visual field) while all other points are seen worse (in the peripheral field) is a successful method of curing squint and improving the sight in cases of squint.

### CASE 3

A very remarkable patient, a girl aged eight, was treated more than fifteen years ago. The vision of the right eye was 2/200 while that of the left eye was 10/200. The right eye turned in most of the time. The vision of the left eye was improved without glasses by alternately resting the eyes.

An attempt was made to teach her how to see best where she was looking. She very soon acquired the ability to practice central fixation when the larger letters were regarded. The child became much interested when she realized that her eyes felt better, while the vision and squint improved. She practiced central fixation on smaller letters and other objects. The strain which was manifest by the contortions of the muscles of her eyes, face, and other parts of her body disappeared. Her voice became more musical with the improvement of her vision and the subsidence of the squint.

#### Microscopic Vision

It was remarkable how well she became able to practice central fixation on very small letters and other objects. She would hold a glass slide on which a small drop of blood was mounted, and claim that **she saw the red cells, the white cells, and other minute particles with her right eye while the glass slide was pressed against her eyelashes.** She was able to read each letter and period in photographic reductions of the Bible, by central fixation.

Many people have complained that they could not see black or imagine a black period for an appreciable length of time. This patient, when palming, stated that black was seen and that with the aid of central fixation even the smallest black periods were seen but they were always moving a distance nearly equal to the width of the period. An effort to see always failed. Distant objects were seen, by central fixation, as far off as it was possible to imagine them.

**This patient was able to produce at will, consciously, and continuously, internal squint of the right eye with the left eye straight or could keep the right eye straight while the left eye turned in.**

## Cases of Squint in the Clinic

By EMILY A. BATES

AMONG the numerous letters we receive from correspondents there was one which drew my attention. Reports of cases are usually from those who have myopia or presbyopia. Cases of squint are less numerous. Most of the patients who have been treated for this trouble have been children whose ages ranged from two years to sixteen years and sometimes up to eighteen. The older ones are usually high school boys. There are just as many cases of squint among girls of school age as there are among boys, but those who have come to me for treatment were mostly boys.

The letter which caught my attention was from a man about 40 years of age who had **squint of the left eye.** This eye also had **myopia and the other eye was farsighted.** The man did not mention this in his letter, but explained how difficult it was for him to do his work under constant strain because of his eye trouble. He had subscribed to the "Better Eyesight" magazine and after reading the reports of squint cases, he mustered up courage enough to write and ask for help. To begin with he had very little money to pay for treatment and yet he did not wish to be a charity case. He had lost his wife when his two sons were quite young. Because of his affliction he had no desire to have a housekeeper in his home to take care of himself and his children. His boys were sent out to board but they were dissatisfied and this worried him. This worry caused still more mental strain to the poor man.

When he first wrote for help we could not admit him into our clinic at the Harlem Hospital because patients who lived outside of the hospital district were not admitted there. We gave him a little help for a while and in each letter he wrote he sent a grateful message for the help we were giving him. People who have not been to Dr. Bates or myself are not encouraged to take up correspondence treatment because it is unsatisfactory and we cannot diagnose a case properly under such conditions. Many have been helped by just reading our books, but they are usually the myopic and presbyopic cases.

We gave this patient an appointment for office treatment and with our help he was able to go on with his work and do it more easily and with less strain. Being employed every day and living about forty miles outside of New York City, he could come but once a week. Anyone who understands the treatment of squint cases will realize how difficult it is to make progress with a patient under these conditions. He was a temperamental type and most sensitive because of his eye trouble. For years he had avoided looking at people's faces and when I first met him his voice trembled when he answered my questions. I knew that mental strain was his main trouble.

I decided that the first thing to do was to speak to him in as low and gentle a voice as possible and see what effect that would have upon him. It was easier to speak to him with my eyes closed and while my eyes were closed I asked him to close his. I noticed that having our eyes closed while we talked had a soothing effect upon him because his voice sounded more relaxed and he was pleased because I spent enough time with him to listen to his troubles and the difficulties he had in taking time to practice with his eyes.

His vision for fine print is now normal at six inches, although it was much impaired when he first came for treatment. His vision for the distance improved but only at times did he have normal vision. Other cases of squint have been treated at the clinic but none received the care that he did because it was not required. The mental strain that he had almost constantly was the principal trouble and a stumbling block in the path of permanent benefit within a reasonable time.

In the beginning of the treatment, when I pointed to a letter of the test card at ten feet he would see it and if he forgot to blink regularly or stared at the letter it would disappear entirely and the test card was immediately a blank to him. The methods for treating him were varied from time to time because it was necessary on account of his mental condition. His vision first improved but then he seemed to lose ground and he stayed away from the clinic for a while. When he again returned he could not talk to me for quite a while nor could I treat him until he had finished weeping, which was an unusual sight to see at the clinic.

It is marvelous the fortitude and the splendid way in which some of our clinic folks go about the cure of their eyes. They have so little time to spend for themselves and yet they find the necessary time, even though it is early in the morning and late at night, to practice as they are directed to do. Patients at the Harlem Hospital Clinic have an advantage over patients in our clinic because they may be seen and treated three days each week, but this poor man had to wait until Saturday before he could come and then there were times when his work prevented him from keeping even these weekly appointments. The day he wept he told me that he had contemplated suicide and was about to do so when he remembered my voice and what I said to him at one time, which was that even though his eyes were crossed, others did not notice it as much as he was conscious of it himself. He also remembered what I said about being a coward and not being brave enough to face life as he had to face it, and that there were others who were less fortunate than he was.

I hope that those who have taken up the Bates Method and are practicing it seriously will have an extra amount of consideration for a man like that. His condition could not be reached or improved until he was relieved of tension and strain. After that was accomplished he improved steadily; he still comes for treatment occasionally. He can now read diamond type at six inches with his left eye and right eye separately and can read the fifteen line of the test card with the left eye at ten feet. Only at times is the squint noticeable.

Another squint case which we had lately was that of a little girl aged eight. She seemed to respond right from the start just for the sake of a smile. When I first became acquainted with her, she looked like a very serious little person who seldom smiled. When I greeted her with a smile and said that I could easily help her condition if she would co-operate with me she settled herself comfortably in the large arm chair where I placed her and after I had tested her sight for the distance and told her that closing her eyes to rest them was a benefit to her, she obeyed me. Her vision when tested on November 24 was 15/10 in the right eye and 15/100 in the left eye, the eye with squint. By practicing the sway and blinking, her vision improved to 15/20 in the left eye the first day, a temporary improvement.

A doctor who was especially interested in this case wrote me a letter asking me if I would see what I could do for her. In his letter he told me that glasses did not help or improve the squint and that her duties at school were a great punishment to her because she could not see the blackboard. While treating her in the beginning I used but one test card, which was a black one with white letters. Closing her eyes, remembering her best doll, and explaining to me how it was dressed, improved her vision considerably for the smaller letters of the card. Shifting while she was seated in her chair, looking first at a blank wall and then at the test card also helped to improve her vision, and as her father looked on he commented upon how straight the eye was as she shifted from the wall to the test card.

Purposely I had her stare to see the letters of the card without shifting and immediately her eye turned in as it had when I first tested her sight. Her father was given directions on how to take care of her eyes at home and she got along very nicely when all of a sudden our little girl stayed away and we did not see her for some time. She had retained the better vision she had shown upon her previous treatment and she again took up her eye work very seriously when she returned. Her sister, who is a few years older than she, came with her from time to time and learned how to help Elizabeth at home. A record was kept, not as regularly as we had wished, but it was enough to convince us that she was doing her part at home. The last time she came she read all of the card at normal distance 10/10 and both eyes were straight during the time she read the card.

When such cases are under treatment we cannot emphasize too strongly that **using the poor eye or the eye with squint for a period of time each day while the good eye is covered with a patch is a benefit to the poor eye and lessens the squint.** I know children do not like to wear a patch, because no one cares to have the eye with good sight covered while the eye under treatment is called upon to see everything for a length of time. At first the patch should be worn for five minutes each day and then the time gradually increased until the patient is able to wear the patch all day long. Every morning and night the test cards should be read with both eyes together and then with the poor eye alone, having the good eye covered.

I do not know of anything which helps more than the long swing, which can be practiced fifty or one hundred times by the patient each morning and night. After the long swing I usually have the patient shorten the swing so that he is able to read one letter at a time of the test card and then sway the body to the left or to the right, whichever is found to be best for the patient. If the right eye turns in it is best to sway to the right and then to the test card which is placed directly in front of the patient. In this way both eyes move at the same time in the same direction and there is no squint visible while the swing and the reading of the test card is going on. When the squint is again noticeable while reading the card and practicing the half swing, it is best to draw the card up a little

closer where the patient has less strain while reading. The squint will then be less and the patient can practice better without any discomfort.

The reason why some cases of squint take longer than others is because the patient does not practice enough at home every day. Cases of squint in adults as well as in children need not only supervision but encouragement from those who are fortunate enough to have good sight. No one with imperfect sight ought to try to help such cases at home or away from our office because it cannot be done successfully. The unconscious strain which is evident when the sight is not perfect always produces more strain in the squint case which is under treatment.

One cannot encourage the patient enough to blink often, do the long swing morning and night as Dr. Bates advises often in his articles in this magazine, and if possible to do the long swing 100 times at least twice daily. **While the long swing is being practiced, both eyes move together and at such times both eyes are straight.** Every day one should notice how long the eye remains straight during treatment. If the eyes remain straight for just a few minutes longer from day to day the improvement will soon be noticed by the patient and this will encourage him to do more practicing.

## Announcements

Dr. Bates wishes to announce that the following have recently completed courses of instruction and are authorized to practice the Bates Method:

Miss Mary E. Wilson,  
2538 Charming Way,  
Berkeley, Calif.

Miss Wilson is the principal of the Anna Head School for Girls in Berkeley and plans to introduce the method into the school for the prevention and cure of imperfect sight in her pupils.

Mr. Harold E. Ensley,  
112 West 104th Street, Tel. Academy 6941,  
and 45 W. 45th Street, New York City, Tel.  
Regent 9483.

Mr. Ensley was formerly a student at Princeton University.

It has come to our attention that certain parties not connected with Dr. Bates in any way are desirous of publishing a periodical called "Better Eyesight." We wish to say that any such use of this title is not with the permission of Dr. Bates or the Central Fixation Publishing Company and that any magazine issued under this title, other than the present one, is not published in the interests of the Bates Method. The title "Better Eyesight" is protected against illegal usage.

We wish to announce that after June, it will be necessary to raise the price of bound volumes of "Better Eyesight" They are now listing at \$3.00 per volume and begin with the year 1923. They contain much valuable information and we would suggest that subscribers secure any volume or volumes which they may desire before the price is raised.

We desire to inform our subscribers that the "Better Eyesight" magazine will be discontinued after the June, 1930, issue. This will enable Dr. Bates and Mrs. Bates to devote more time to the writing of new books on treatment alone for which there has been a very great demand during the past year. Subscriptions for the remaining months, however, are being received. We request that all those who desire to be notified upon the publication of new books kindly send us their names and addresses, which will be kept on file.

**March, 1930**

1 - "Text-Book of Ophthalmology," authorized translation from the twelfth German edition by Duane, p. 795.

APRIL, 1930

## The Optimum Swing

**The optimum swing is the swing which gives the best results under different conditions.**

Most readers of this magazine and of "Perfect Sight Without Glasses" know about **the swing**. The swing may be spontaneous; that is to say, when one remembers a letter perfectly or sees a letter perfectly and continuously without any volition on his part he is able to imagine that it has a **slow, short, easy swing. The speed is about as fast as one would count orally. The width of the swing is not more than the width of the letter**, and it is remembered or imagined as easily as it is possible to imagine anything without any effort whatsoever. The normal swing of normal sight brings the greatest amount of relaxation and should be imagined. When one is able to succeed then it becomes the optimum swing under favorable conditions. Nearsighted persons have this normal optimum swing usually at the near point when the vision is perfect. At the distance where the vision is imperfect the optimum swing is something else. It is not spontaneous but has to be produced by a conscious movement of the eyes and head from side to side and is usually wider than the width of the letter, faster than the normal swing, and not so easily produced.

When one has a headache or a pain in the eyes or in any part of the body the optimum swing is always wider and more difficult to imagine than when one has less strain of the eyes. Under un-favorable conditions the long swing is the optimum swing, but under favorable conditions when the sight is good, the normal swing of the normal eye with normal sight is the optimum swing.

**The long swing brings a measure of relief when done right and makes it possible to shorten it down to the normal swing of the normal eye.**

## Vision and Education

By W. H. BATES, M.D.

POOR sight is admitted to be one of the most fruitful causes of retardation in the schools. It is estimated that it may reasonably be held responsible for a quarter of the habitually "left-backs," and it is commonly assumed that all this might be prevented by suitable glasses.

There is much more involved in defective vision, however, than mere inability to see the blackboard, or to use the eyes without pain or discomfort. Defective vision is the result of an abnormal condition of the mind, and when the mind is in an abnormal condition it is obvious that none of the processes of education can be conducted with advantage. By putting glasses upon a child we may, in some cases, neutralize the effect of this condition upon the eyes and by making the patient more comfortable may improve his mental faculties to some extent, but we do not alter fundamentally the condition of the mind and by confirming it in a bad habit we may make it worse.

It can easily be demonstrated that among the faculties of the mind which are impaired when the vision is impaired is the memory; and as a large part of the educational process consists of storing the mind with facts, and all the other mental processes depend upon one's knowledge of facts, it is easy to see how little is accomplished by merely putting glasses on a child that has "trouble with its eyes." **The extraordinary memory of primitive people has been attributed to the fact that, owing to the absence of any convenient means of making written records, they had to depend upon their memories, which were strengthened accordingly; but in view of the known facts about the relation of memory to eyesight it is more reasonable to suppose that the retentive memory of primitive man was due to the same cause as his keen vision: namely, a mind at rest.**

## Telescopic Vision

The primitive memory as well as primitive keenness of vision have been found among civilized people, and if the necessary tests had been made it would doubtless have been found that they always occur together, as they did in a case which recently came under my observation.

The subject was a child of ten with such marvelous eyesight that she could **see the moons of Jupiter with the naked eye**, a fact which was demonstrated by her drawing a diagram of these satellites which exactly corresponded to the diagrams made by persons who had used a telescope. Her memory was equally remarkable. She could recite the whole content of a book after reading it, as Lord Macauley is said to have done, and she learned more Latin in a few days without a teacher than her sister, who had six diopters of myopia, had been able to do in several years. She remembered five years afterward what she ate at a restaurant, she recalled the name of the waiter, the number of the building and the street in which it stood. She also remembered what she wore on this occasion and what everyone else in the party wore. The same was true of every other event which had awakened her interest in any way, and it was a favorite amusement in her family to ask her what the menu had been and what people had worn on particular occasions.

When the sight of two persons is different it has been found that their memories differ in exactly the same degree. Two sisters, one of whom had only ordinary good vision, indicated by the formula 20/20, while the other had 20/10, found that the time it took them to learn eight verses of a poem varied in almost exactly the same ratio as their sight. The one whose vision was 20/10 learned eight verses of the poem in fifteen minutes, while the one whose vision was only 20/20 required thirty-one minutes to do the same thing. After palming, the one with ordinary vision learned eight more verses in twenty-one minutes, while the one with 20/10 was only able to reduce her time by two minutes, a variation clearly within the limits of error. In other words, the mind of the latter being already in a normal or nearly normal condition, she could not improve it appreciably by palming, while the former, whose mind was under a strain, was able to gain relaxation, and hence improve her memory, by this means.

**When the two eyes of the same person are different a corresponding difference in the memory** has been noted according to whether both eyes were open, or the better eye closed.

+ A patient with normal vision in the right eye and half-normal vision in the left when looking at the Snellen test card with both eyes open could remember a period for twenty seconds continuously, but could remember it only ten seconds when the better eye was closed.

+ A patient with half-normal vision in the right eye and one-quarter normal in the left could remember a period for twelve seconds with both eyes open and only six seconds with better eye closed.

+ A third patient with normal sight in the right eye and vision of one-tenth in the left could remember a period twelve seconds with both eyes open and only two seconds when the better eye was closed. In other words if the right eye is better than the left the memory is better when the right eye is open than when only the left eye is open.

#### School Children

Under the present educational system there is a constant effort to compel the children to remember. These efforts always fail. They spoil both the memory and the sight. The memory cannot be forced any more than the vision can be forced. We remember without effort, just as we see without effort, and the harder we try to remember or see the less we are able to do so.

+ The sort of things we remember are the things that interest us, and the reason children have difficulty in learning their lessons is because they are bored by them. For the same reason, among others, their eyesight becomes impaired, boredom being a condition of mental strain in which it is impossible for the eye to function normally.

Some of the various kinds of compulsion now employed in the educational process may have the effect of awakening interest. Betty Smith's interest in winning a prize, for instance, or in merely getting ahead of Johnny Jones, may have the effect of rousing her interest in lessons that have hitherto bored her, and this interest may develop into a genuine interest in the acquisition of knowledge; but this cannot be said of the various fear incentives still so largely employed by teachers. These, on the contrary, have the effect, usually, of completely paralyzing minds already numbed by lack of interest, and the effect upon the vision is equally disastrous. Boredom, fear tactics in school causes mental strain, unclear vision.

The fundamental reason, both for poor memory and poor eyesight in school children, in short, is our irrational and unnatural educational system. Montessori has taught us that it is only when children are interested that they can learn. It is equally true that it is only when they are interested that they can see. This fact was strikingly illustrated in the case of one of the two pairs of sisters mentioned above. Phebe, of the keen eyes, who could recite whole books if she happened to be interested in them, disliked mathematics and anatomy extremely, and not only could not learn them but became myopic when they were presented to her mind. She could read letters a quarter of an inch high at twenty feet in a poor light, but when asked to read figures one to two inches high in a good light at ten feet she miscalled half of them. When asked to tell how much 2 and 3 made, she said "4," before finally deciding on "5"; and all the time she was occupied with this disagreeable subject the retinoscope showed that she was myopic. When I asked her to look into my eye with the ophthalmoscope she could see nothing, although a much lower degree of visual acuity is required to note the details of the interior of the eye than to see the moons of Jupiter.

Short-sighted Isabel, on the contrary, had a passion for mathematics and anatomy, and excelled in those subjects. She learned to use the ophthalmoscope as easily as Phebe had learned Latin. Almost immediately she saw the optic nerve, and noted that the center was whiter than the periphery. She saw the light-colored lines, the arteries; and the darker ones, the veins; and she saw the light streaks on the blood-vessels. Some specialists never become able to do this, and no one could do it without normal vision. Isabel's vision, therefore, must have been temporarily normal when she did it. Her vision for figures, although not normal, was better than for letters.

In both these cases the ability to learn and the ability to see went hand in hand with interest. Phebe could read a photographic reduction of the Bible and recite what she had read verbatim, she could see the moons of Jupiter and draw a diagram of them afterwards, because she was interested in these things; but she could not see the interior of the eye, nor see figures even half as well as she saw letters, because these things bored her. When, however, it was suggested to her that it would be a good joke to surprise her teachers, who were always reproaching her for her backwardness in mathematics, by taking a high mark in a coming examination, her interest in the subject awakened and she contrived to learn enough to get seventy-eight percent. In Isabel's case letters were antagonistic. She was not interested in most of the subjects with which they dealt and, therefore, she was backward in those subjects and had become habitually myopic. But when asked to look at objects which aroused an intense interest her vision became normal.

When one is not interested, in short, one's mind is not under control, and without mental control one can neither learn nor see. Not only the memory but all other mental faculties are improved when the eyesight becomes normal. It is a common experience with patients cured of defective sight to find that their ability to do their work has improved.

A teacher whose letter was quoted in an early issue of "Better Eyesight" testified that after gaining perfect eyesight she "knew better how to get at the minds of the pupils," was "more direct, more definite, less diffused, less vague," possessed, in fact, "central fixation of the mind." In another letter she said, "The better my eyesight becomes the greater is my ambition. On the days when my sight is best I have the greatest anxiety to do things."

Another teacher reported that one of her pupils used to sit doing nothing all day long and apparently was not interested in anything. After the test card was introduced into the classroom and his sight improved, he became anxious to learn, and speedily developed into one of the best students in the class. In other words his eyes and his mind became normal together.

Improving close and distant vision activates and integrates the left and right brain hemispheres, improves all left and right hemisphere functions: math, science, art, music, sports, speech, relaxation, energy level... Exercises to activate and integrate the left and right hemispheres improves the clarity of vision at all distances.

**A bookkeeper nearly seventy years of age who had worn glasses for forty years** found after he had gained perfect sight without glasses that he could work more rapidly and accurately and with less fatigue than ever in his life before. During busy seasons, or when short of help, he has worked for some weeks at a time from 7 A.M. until 11 P.M. and he reports that he felt less tired at night after he was through than he did in the morning when he started. Previously, although he had done more work than any other man in the office, it always tired him very much. He also noticed an improvement in his temper. Having been so long in the office and knowing so much more about the business than his fellow employees, he was frequently appealed to for advice. These interruptions, before his sight became normal, were very annoying to him and often caused him to lose his temper. Afterward, however, they caused him no irritation whatever. In the case of another patient whose story follows, symptoms of insanity were relieved when the vision became normal.

From all these facts it will be seen that the problems of vision are far more intimately associated with the problems of education than we had supposed, and that they can by no means be solved by putting concave, or convex, or astigmatic lenses before the eyes of the children.

One of the most striking cases of the relation of mind to vision that ever came to my attention was that of a physician whose mental troubles, at one time so serious that they suggested to him the idea that he might be going insane, were completely relieved when his sight became normal. He had been seen by many eye and nerve specialists before he came to me and consulted me at last, not because he had any faith in my methods, but because nothing else seemed to be left for him to do. He brought with him quite a collection of glasses prescribed by different men, no two of them being alike. He had worn glasses, he told me, for many months at a time without benefit, and then he had left them off and had been apparently no worse. Outdoor life had also failed to help him. On the advice of some prominent neurologists he had even given up his practice for a couple of years to spend the time upon a ranch, but the vacation had done him no good.

I examined his eyes and found no organic defects and no error of refraction. Yet his vision with each eye was only three-fourths of the normal, and he suffered from double vision and all sorts of unpleasant symptoms. He used to see people standing on their heads, and little devils dancing on the tops of the high buildings. He also had other illusions too numerous to mention in a short paper. At night his sight was so bad that he had difficulty in finding his way about, and when walking along a country road he believed that he saw better when he turned his eyes far to one side and viewed the road with the side of the retina instead of with the center. At variable intervals, without warning and without loss of consciousness, he had attacks of blindness. These caused him great uneasiness, for he was a surgeon with a large and lucrative practice, and he feared that he might have an attack while operating.

His memory was very poor. He could not remember the color of the eyes of any member of his family, although he had seen them all daily for years. Neither could he recall the color of his house, the number of rooms on the different floors, or other details. The faces and names of patients and friends he recalled with difficulty, or not at all.

His treatment proved to be very difficult, chiefly because he had an infinite number of erroneous ideas about physiological optics in general and his own case in particular, and insisted that all these should be discussed; while these discussions were going on he received no benefit. Every day for hours at a time over a long period he talked and argued. Never have I met a person whose logic was so wonderful, so apparently unanswerable, and yet so utterly wrong.

His eccentric fixation was of such high degree that when he looked at a point forty-five degrees to one side of the big C on the Snellen test card, he saw the letter just as black as when he looked directly at it. The strain to do this was terrific, and produced much astigmatism; but the patient was unconscious of it, and could not be convinced that there was anything abnormal in the symptom. If he saw the letter at all, he argued, he must see it as black as it really was, because he was not color-blind. Finally he became able to look away from one of the smaller letters on the card and see it worse than when he looked directly at it. It took eight or nine months to accomplish this, but when it had been done the patient said that it seemed as if a great burden had been lifted from his mind. He experienced a wonderful feeling of rest and relaxation throughout his whole body.

When asked to remember black with his eyes closed and covered he said he could not do so, and he saw every color but the black which one ought normally to see when the optic nerve is not subject to the stimulus of light. He had, however, been an enthusiastic football player at college, and he found at last that he could remember a black football. I asked him to imagine that this football had been thrown into the sea and that it was being carried outward by the tide, becoming constantly smaller but no less black. This he was able to do, and the strain floated with the football, until, by the time the latter had been reduced to the size of a period in a newspaper, the strain was entirely gone. The relief continued as long as he remembered the black spot, but as he could not remember it all the time, I suggested another method of gaining permanent relief. This was to make his sight voluntarily worse, a plan against which he protested with considerable emphasis.

"Good heavens!" he said, "Is not my sight bad enough without making it worse?"

After a week of argument, however, he consented to try the method, and the result was extremely satisfactory. After he had learned to see two or more lights where there was only one, by straining to see a point above the light while still trying to see the light as well as when looking directly at it, he became able to avoid the unconscious strain that had produced his double and multiple vision and was not troubled by these superfluous images any more. In a similar manner other illusions were prevented.

One of the last illusions to disappear was his belief that an effort was required to remember black. His logic on this point was overwhelming, but after many demonstrations he was convinced that no effort was required to let go, and when he realized this, both his vision and his mental condition immediately improved.

He finally became able to read 20/10 or more, and although more than fifty-five years of age, he also read diamond type at from six to twenty-four inches. His night blindness was relieved, his attacks of day blindness ceased, and he told me the color of the eyes of his wife and children. One day he said to me:

"Doctor, I thank you for what you have done for my sight; but no words can express the gratitude I feel for what you have done for my mind."

Some years later he called with his heart full of gratitude, because there had been no relapse.

#### LYING AS A CAUSE OF MYOPIA

I may claim to have discovered the fact that telling lies is bad for the eyes. Whatever bearing this circumstance may have upon the prevalence of defects of vision, it can easily be demonstrated that it is impossible to say what is not true, even with no intent to deceive, or even to imagine a falsehood, without producing an error of refraction.

If a patient can read all the small letters on the bottom line of the test card, and either deliberately or carelessly miscalls any of them, the retinoscope will indicate an error of refraction. In numerous cases patients have been asked to state their ages incorrectly, or to try to imagine that they were a year older, or a year younger, than they actually were, and in every case when they did this the retinoscope indicated an error of refraction. A patient twenty-five years old had no error of refraction when he looked at a blank wall without trying to see; but if he said he was twenty-six, or if someone else said he was twenty-six, or if he tried to imagine that he was twenty-six, he became myopic. The same thing happened when he stated or tried to imagine that he was twenty-four. When he stated or remembered the truth his vision was normal, but when he stated or imagined an error he had an error of refraction.

Two little girl patients arrived one after the other one day, and the first accused the second of having stopped for an ice-cream soda, which she had been instructed not to do, being somewhat too much addicted to sweets. The second denied the charge, and the first, who had used the retinoscope and knew what it did to people who told lies, said

"Do take the retinoscope and find out."

I followed the suggestion, and having thrown the light into the second child's eye, I asked:

"Did you go to Huyler's?"

"Yes," was the response, and the retinoscope indicated no error of refraction.

"Did you have an ice-cream soda?"

"No," said the child; but the tell-tale shadow moved in a direction opposite to that of the mirror, showing that she had become myopic and was not telling the truth.

The child blushed when I told her this and acknowledged that the retinoscope was right, for she had heard of the ways of the uncanny instrument before and did not know what else it might do to her if she said anything more that was not true.

The fact is that it requires an effort to state what is not true, and this effort always results in a deviation from the normal in the refraction of the eye. So sensitive is the test that if the subject, whether his vision is ordinarily normal or not, pronounces the initials of his name correctly while looking at a blank surface without trying to see, there will be no error of refraction; but if he miscalls one initial, even without any consciousness of effort, and with full knowledge that he is deceiving no one, myopia will be produced.

## Suggestions for Myopic Patients

By EMILY A. BATES

IN THE morning when you awaken, before getting out of bed, sit up and **palms**. *Memory helps.* While palming, the **memory** of a flower or of the color of it, of a white cloud with the sun shining behind it, of the blue of the sky, or of any pleasant thing that you can remember perfectly, something that you have seen perfectly, helps. If nothing else can be remembered you can imagine part of the test card and when you imagine some of the letters with your eyes closed and imagine the form of each letter, not trying to remember any particular letter any length of time, because that is a strain, your mind will be relaxed when you get out of bed.

After arising, practice the **sway**. Always **blink** while swaying. After the sway do the **long swing**; let your head and eyes alone, allow your body to do the moving. Pay no attention to stationary objects which appear to be moving as you swing. After practicing the long swing, keep up the blinking while dressing, but do not blink fast. The eyes move gently with every blink and that is a rest. You will notice that heretofore you have stared.

If the **test cards** can be used for practice before going to business, so much the better. Place the "C" card to the right of you, a little more than arm's length away. Place the black card to the left of you, also a little more than arm's length away. Then place the number card to the left six feet away, and the inverted "E" card to the right of you six feet away. Now start the sway. Pay no attention to anything, but just keep looking right ahead of you at the wall. Blink and keep up the sway. Notice that all cards appear to be moving opposite to the movement of your body. Blink. *Never stop blinking*, still noticing that the cards move opposite to the movement of the sway. *Do not sway too fast; take it easy.* Better vision comes without effort. Notice that when things become too blurred that you are staring, that you have forgotten to blink.

When it is noticed that the cards appear to be moving opposite to the movement of the body, then start the long swing, flashing a letter of the "C" card as you swing to the right, then noticing a letter on a line of the black card as you swing to the left. Be sure to move your body and not only your head and eyes. Don't forget to blink. Then while keeping up the long swing, flash a numeral on the number card to the left and then as you swing to the right, flash an inverted "E" on any line of that card. Every day see if you can flash a smaller numeral on one of the lower lines of the number card as well as an "E" pointing either to the right, left, up, or down on one of the lower lines of the "E" card.

The improvement in your vision all depends upon the time that you have to practice in the above way.

If **sun treatment** can be given on the closed eyelids by placing yourself in the sun, raising your head, and letting the sun shine on the closed eyelids for five minutes or longer, it will help to improve the vision when doing the long swing.

If palming is irksome, just sit comfortably and close the eyes, remembering something pleasant every time the eyes are being rested in this way.

Alternate practicing with the distant cards by placing yourself at a desk. When writing for practice always place your small black card to the right or to the left of your desk and after writing a sentence or two, raise your head and look over to the card at any letter that you see easily without straining. It helps to close the eyes immediately afterward, remembering that letter. Write a few more sentences, again glancing at the card after raising your head in the direction of the letters and not trying hard to see any particular letter.

**Palm and remember.** imagine a flower, its color, white cloud with sun shining behind it, blue sky and any pleasant objects, scenery that is easily remembered clear, perfect.

See objects clear, in color, motion: wind blowing green grass, pink, blue, purple, red, orange... flowers, yellow black bee with golden pollen on its legs, rainbow colors in its clear wings flying about the garden.

Sway left and right in front of 4 eyecharts. Blink. Notice the charts appear to move past in the opposite direction to the movement of the body. (More movement is seen with the charts at close distances before 20 ft.) Shift without effort on a letter on the charts for a second, fraction of a second when swaying in the direction of a chart. No effort to see. No staring. Keep moving. Relax. Do the same with the Long Swing. Swing right and 'shift for a fraction of a second' 'flash' on the letter C on the chart on the right. Then swing left and 'flash' the letter C on the chart on the left. Then, flash a number on the card on the left when moving left and flash an inverted E on the E card when moving right. Practice flashing, seeing clear smaller letters at various distances.

Charts can also be placed on the left and right sides of a open window. Sway and swing left and right and shift, flash the letters on the left and right charts as described above. Shift on distant objects outside the window. Practice day and night.

When large test cards are not used for practice, place two small cards on the window sill if possible and while swaying shift from one card to the other.

## Announcements

It has come to our attention that certain parties not connected with Dr. Bates in any way are desirous of publishing a periodical called "Better Eyesight." We wish to say that any such use of this title is not with the permission of Dr. Bates or the Central Fixation Publishing Company and that any magazine issued under this title, other than the present one, is not published in the interests of the Bates Method. The title "Better Eyesight" is protected against illegal usage.

After June, it will be necessary to raise the price of bound volumes of "Better Eyesight." They are now listing at \$3.00 per volume and begin with the year 1923. They contain much valuable information and we would suggest that subscribers secure any volume or volumes which they may desire before the price is raised.

We desire to inform our subscribers that the "Better Eyesight" magazine will be discontinued after the June, 1930, issue. This will enable Dr. Bates and Mrs. Bates to devote more time to the writing of new books on treatment alone for which there has been a very great demand during the past year. Subscriptions for the remaining months, however, are being received. We request that all those who desire to be notified upon the publication of new books kindly send us their names and addresses, which will be kept on file.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

MAY, 1930

### Methods that Have Succeeded in Presbyopia

The cure of presbyopia, as of any other error of refraction, is rest, and many presbyopic patients are able to obtain this rest simply by closing the eyes. They are kept closed until the patient feels relieved, which may be in a few minutes, half an hour, or longer. Then some fine print is regarded for a few seconds. By alternately resting the eyes and looking at fine print many patients quickly become able to read it at eighteen inches, and by continued practice they are able to reduce the distance until it can be read at six inches in a dim light. At first the letters are seen only in flashes. Then they are seen for a longer time, until finally they are seen continuously. When this method fails, palming may be tried, combined with the use of the memory, imagination and swing. Particularly good results have been obtained from the following procedure:

- + Close the eyes and remember the letter o in diamond type, with the open space as white as starch and the outline as black as possible.
- + When the white center is at the maximum imagine that the letter is moving, and that all objects, no matter how large or small, are moving with it. Shift on the letter.
- + Open the eyes and continue to imagine the universal swing.
- + Alternate the imagination of the swing with the eyes open with its imagination with the eyes closed.
- + When the imagination is just as good with the eyes open as when they are closed the cure will be complete.

## Presbyopia: Its Cause and Cure

By W. H. BATES, M.D.

(Cures for Presbyopia Cure Cataract and other Eye Disease.)

PRESBYOPIA is the name given to the loss of power to use the eyes at the near point, without the aid of glasses, which usually occurs after the age of forty.

The text-books teach that this change is a normal one: but it is a noteworthy fact that many other eye troubles often date from the time of its appearance, or develop a little later. Many cases of glaucoma start about this time, and so do many cases of cataract and inflammation of the interior of the eye. Patients with presbyopia are very likely to have conjunctivitis. They are also subject to congestion and hemorrhages of the interior of the eye. One patient developed a lot of muscular trouble and a marked degree of double vision at the time he became presbyopic, and suffered three nervous breakdowns in quick succession. He was operated on for the muscular condition, and took prism exercises, but obtained very little relief. In another case a patient began to suffer, at the time she became unable to read without glasses, from a contraction of the muscles of the face, congestion of the conjunctiva and continual headaches. The strain was so great that she had to keep her eyes partly closed, and glasses did nothing to relieve her discomfort. Up to the time when her presbyopia appeared she had had none of these troubles.

The accepted explanation for the loss of near vision with advancing years is that it is due to the hardening of the lens, but it is quite impossible to reconcile the facts with this theory; for not only does presbyopia occur much below the age of forty and even in childhood, but it is often delayed beyond the age of fifty, and sometimes does not occur at all. There are also cases in which near vision is restored after having been lost. We are told that presbyopia comes early in the hypermetropic (farsighted) eye, and late in the myopic (nearsighted) eye; that premature hardening of the lens and weakness of the ciliary muscle (supposed to control the accommodation) may cause it to appear in youth; and that the swelling of the lens in incipient cataract may account for the restoration of near vision after it has been lost; but there are still many cases to which these explanations cannot be made to apply.

65 year old man cures unclear close vision

It is true that hypermetropia does hasten and myopia prevent or postpone the advent of presbyopia, and as myopia may exist in only one eye, without the patient's being aware of it, he may think that his vision is normal both for the near-point and the distance. There are cases, however, in which the vision has remained absolutely normal in both eyes long after the presbyopic age, and a considerable number of these cases have been brought to my attention. One of them, a man of sixty-five, examined in a moderate light indoors, was found to have a vision of 20/10. In other words he could see twice as far as the normal eye is expected to see. He also read diamond type at less than six inches, and at other distances, to more than eighteen inches. In reply to a query as to how he came to possess visual powers so unusual at his age, or, indeed, at any age, he said that when he was about forty he began to experience difficulty, at times, in reading. He consulted an optician who advised glasses. He could not believe, however, that the glasses were necessary, because at times he could read perfectly without them. The matter interested him so much that he began to observe facts, a thing that people seldom do. He noted, first, that when he tried hard to see either at the near-point or at the distance, his vision invariably became worse, and the harder he tried the worse it became. Evidently something was wrong with this method of using the eyes. Then he tried looking at things without effort, without trying to see them. He also tried resting his eyes by closing them for five minutes or longer, or by looking away from the page that he wished to read, or the distant object he wished to see. These practices always improved his sight, and by keeping them up he not only regained normal vision but retained it for twenty-five years.

"Doctor," he said, in concluding his story, "when my eyes are at rest and comfortable, my vision is always good and I forget all about them. When they do not feel comfortable I never see so well, and then I always proceed to rest them until they feel all right again."

The fact is that presbyopia is due to a strain. It is a strain similar to the one that produces hypermetropia, (farsight, unclear close vision) but differs from it in the fact that it affects chiefly vision at the near-point (close reading distance). This can be demonstrated with the retinoscope. When a person with presbyopia tries to read, the retinoscope will show that he has hypermetropia, but when he looks at a distant object the retinoscope will show either that his eyes are normal, or that the hypermetropia is less. Simultaneous retinoscopy is difficult in the case of a reading patient, for not only is the pupil small, but in order to find the shadow it is necessary for the patient to look in one general direction all the time, and this is not easy. It is also difficult to hold a glass at one side of the eye for the measurement of the refraction in such a way that the observer can look through it while the patient does not. With a sufficient zeal for the truth, however, these difficulties can be overcome.

Eye-glasses increase vision impairment and leads to development of eye diseases, problems.

The strain which produces presbyopia is accompanied by a strain, more or less pronounced, of all the other nerves of the body. Hence the many distressing symptoms from which presbyopic patients suffer. Glasses, by neutralizing the effect of the imperfect action of the muscles, may enable the patient to read; but they cannot relieve any of these strains. On the contrary they usually make them worse, and it is a matter of common experience that the vision declines rapidly after the patient begins to wear them. When people put on glasses because they cannot read fine print they often find that in a couple of weeks they cannot, without them, read the coarse print that was perfectly plain to them before. Occasionally the eye resists the artificial conditions imposed upon them by glasses to an astonishing degree, as in the case of a woman of seventy who had worn glasses for twenty years, in spite of the fact that they tired her eyes and blurred her vision, but was still able to read diamond type without them. This however is very unusual. As a rule the eyes go from bad to worse, and, if the patient lives long enough, he is almost certain to develop some serious disease which ends so frequently in blindness that nearly half of our blind population at the present time is believed to be over sixty years of age. Persons with presbyopia who are satisfied with the relief given to them by glasses should bear this fact in mind.

Presbyopia is cured just as any other error of refraction is cured, by rest. But there is a great difference in the way patients respond to this treatment. Some are cured very quickly, even in as short a time as fifteen minutes; others are very slow; but as a rule relief is obtained within a reasonable time.

**One of my earliest cures of presbyopia was accomplished in less than fifteen minutes** by the aid of the imagination. The patient had worn glasses for reading for ten years. When I showed him a specimen of diamond type and asked him to read it without glasses he said he knew the letters were black but they looked grey.

"If you know they are black, and yet see them grey," I said, "you must imagine that they are grey. Suppose you imagine that they are black. Can you do that?"

"Yes," he said, "I can imagine that they are black," and immediately he proceeded to read them.

In another case a patient was cured simply by closing his eyes for half an hour. His wife was cured in the same way, and when I saw the couple six months later they had had no relapse. Both had worn reading glasses for more than five years.

Old Gentleman cures his presbyopia by reading, writing fine, microscopic print.

While it is sometimes very difficult to cure presbyopia, it is, fortunately, very easy to prevent it. Oliver Wendell Holmes told us how to do it in "The Autocrat of the Breakfast Table," and it is astonishing not only that no attention whatever should have been paid to his advice, but that we should have been warned against the very course which was found so beneficial in the case he records.

**"There is now living in New York State," he says, "an old gentleman who, perceiving his sight to fail, immediately took to exercising it on the finest print, and in this way fairly bullied Nature out of her foolish habit of taking liberties at the age of forty-five or thereabouts. And now this old gentleman performs the most extraordinary feats with his pen, showing that his eyes must be a pair of microscopes. I should be afraid to say how much he writes in the compass of a half-dime, whether the Psalms or the Gospels, or the Psalms and the Gospels, I won't be positive."**

Persons whose sight is beginning to fail at the near-point, or who are approaching the presbyopic age, should imitate the example of this remarkable old gentleman. Get a specimen of diamond type, and read it every day in an artificial light, bringing it closer and closer to the eye till it can be read at six inches or less. Or get a specimen of type reduced by photography until it is much smaller than diamond type, and do the same. (microscopic type/print) You will thus escape, not only the necessity of wearing glasses for reading and near work, but all of those eye troubles which now so often darken the later years of life.

## Test Card Practice

By EMILY A. BATES

Editor's Note—The following is taken from Mrs. Bates' (Lierman) book, "Stories From The Clinic". Although the majority of our subscribers have Mrs. Bates' book, we believe that these suggestions can always be read with benefit.

1. Every home should have a test card.
2. It is best to place the card permanently on the wall in a good light.
3. Each member of the family or household should read the card every day.
4. It takes only a minute to test the sight with the card. If you spend five minutes in the morning practicing, it will be a great help during the day.
5. Place yourself ten feet from the card and read as far as you can without effort or strain. Over each line of letters are small figures indicating the distance at which the normal eye can read them. Over the big C at the top of the card is the figure 200. The big C, therefore, should be read by the normal eye at a distance of two hundred feet. If you can read this line at ten feet, your vision would be 10/200. The numerator of the fraction is always the distance of the card from the eyes. The denominator always denotes the number of the line read. If you can only read the line marked 40 at ten feet, the vision is 10/40.

20 FT.  
20 LINE

Read the test card daily in good light, sunlight is best. Shift on a letter and remember, imagine it clear, correct with the eyes open, then in the imagination with the eyes closed, then with the eyes open again. Repeat. Blink. Practice on smaller letters. Practice with both eyes together, one eye at a time, then both eyes together again. Practice with the chart at various distances 5 ft. to 200 ft. Practice on fine print at 20 inches and closer to 3, 2, 1, inches from the eyes.

6. If you can only see the fifth line, for example, notice that the last letter on that line is an R. Now close your eyes, cover them with the palms of the hands and remember the R. If you will remember that the left side is straight, the right side partly curved, and the bottom open, you will get a good mental picture of the R with your eyes closed. This mental picture will help you to see the letter directly underneath the R, which is a T.
7. Shifting is good to stop the stare. If you stare at the letter T, you will notice that all the letters on that line begin to blur. It is beneficial to close your eyes quickly after you see the T, open them, and shift to the first figure on that line, which is a 3. Then close your eyes and remember the 3. You will become able to read all the letters on that line by closing your eyes for each letter.

8. Keep a record of each test in order to note your progress from day to day.
9. When you become able to read the bottom line with each eye at ten feet; your vision is normal for the distance, 10/10.

10. The distance of the Snellen test card from the patient is a matter of considerable importance. However, some patients improve more rapidly when the card is placed fifteen or twenty feet away, while others fail to get any benefit with the card at this distance. In some cases the best results are obtained when the card is as close as one foot. Others with poor vision may not improve when the card is placed at ten feet or further, or at one foot or less, but do much better when the card is placed at a middle distance, at about eight feet. Some patients may not improve their vision at all at ten feet, but at one foot. While some patients are benefited by practicing with the card daily, always at the same distance, there are others who seem to be benefited when the distance of the card from the patient is changed daily.

Experiment with the test card placed at a variety of close, middle, far distances.

## Better Eyesight in Schools

By a Superintendent of Public Schools

Editor's Note -The following was written by a superintendent of public schools who not only helped his own eyes, but also helped the nurses to help the children. Permission was given these nurses to attend the clinic so that they could test the vision of each child and make records accordingly. Further advice was given by Dr. and Mrs. Bates and the work was carried on so that within a year's time it was noticed by those not interested in the Bates Method that there were less eye-glasses being worn by the school children.

UNDER the direction of our school nurse, a Snellen test of the eyes of all our pupils was made. A novel health experiment was begun, a campaign for "Better Eyesight." A second test was made in order to verify the value and progress in this phase of health work which showed marvelous, practical, successful results. Only the skepticism of principals, teachers and pupils, and the lack of faithfulness in carrying out its conditions, prevented the wonderful results achieved from paralleling those of an Arabian Night's story.

A Snellen test card was placed permanently in the class rooms. The children were directed to read the smallest letters they could see from their seats at least once every day, with both eyes together and with each eye separately, the other being covered with the palm of the hand in such a way as to avoid pressure of the eyeball. Those whose vision was defective were encouraged to read it more frequently, and in fact needed no encouragement to do so after they found that the practice helped them to see the blackboard, and stopped the headaches, or other discomfort, previously resulting from the use of their eyes.

Some years ago the same system was introduced into some of the schools of New York City with an attendance of about ten thousand children. Many of the teachers neglected to use the cards, being unable to believe that such a simple method and one so

entirely at variance with previous teaching on the subject, could accomplish the desired results. Others kept the cards in a closet except when they were needed for the daily eye drill, lest the children should memorize them. Thus they not only put an unnecessary burden upon themselves, but did what they could to defeat the purpose of the system, which is to give the children daily exercise in distant vision with a familiar object as the point of fixation. A considerable number, however, used the system intelligently and persistently, and in less than a year were able to present reports showing that of three thousand children with imperfect sight over one thousand had obtained normal vision by its means.

Not only does this work place no additional burden upon the teachers, but, by improving the eyesight, health, disposition and mentality of their pupils, it greatly lightens their labors.

### Questions and Answers

Q—It is difficult for me to find time enough to gain perfect relaxation. What would you suggest?

A—You have just as much time to relax as you have to strain. **Practice relaxation all day long.** Whenever you move your head or eyes, notice that stationary objects move in the direction opposite to the movement of your head or eyes. When walking about the room or on the street, the floor or pavement appears to come toward you, while objects on either side of you move in the direction opposite to the movement of your body. Remember to blink frequently just as the normal eye does. Constantly shift your eyes from one point to another seeing the point regarded more clearly than all other parts. When talking with anyone, do not stare. Look first at one eye and then the other, remembering to blink. Shift from the eyes to the nose, to one cheek and then to the other, then to the mouth, the chin, and back to the forehead.

Notice when looking in a persons eyes: if their eyes move, your eyes move. If a person stares, eyes immobile, keep your eyes moving when looking into their eyes and you will prevent staring in your eyes and help the person obtain normal eye movement.

Q—Why is it that I have perfect vision only in flashes? Can these flashes become permanent?

A—You have not yet lost your unconscious habit of straining. When relaxation methods are practiced faithfully at all times, the flashes of improved vision become more frequent and last longer until the vision becomes continuously good.

Q—What causes **twitching eyelids**?

A—Strain causes twitching eyelids and this is relieved by rest and relaxation. Palming, sun treatment, swinging, blinking are very beneficial.

Q—Can you explain why I see yellow and blue spots after looking at the sun?

A—You are straining. Do not look directly at the sun until your eyes are more accustomed to it. Practice the sun treatment—sit in the sun with the eyes closed. Allow the sun to shine directly upon your closed eyelids, as you slowly move your head a short distance from side to side. Do this for half an hour or longer as often as possible whenever the sun is shining.

Modern teachers state to not look into the sun with the eyes open.

Look to the side, out to the bright sky, clouds. Blink, shift continually, easy, relaxed, move the head and eyes. Daydream something pleasant.

Q—Is working or reading under electric light harmful? Should a shade be worn?

A—It is not harmful to read by electric light if the eyes are used properly. Do not wear a shade or any other protection for the eyes. Practice sun treatment.

Q—When remembering a black period, I see a bright disk with a small black center. Is this seeing a period?

A—No. you are straining. The period that you imagine is very imperfect, because to remember the period and at the same time a very bright disk, is an unconscious strain. You cannot strain and remember the bright disk, and simultaneously relax and remember a black period. When your bright disk is prominent, everything else is remembered under a strain. You cannot strain and relax at the same time.

### Announcements

We take pleasure in announcing that the following have recently completed courses of instruction at Dr. Bates' office and are qualified to practice the Bates Method:

Dr. Paul J. Dodge,  
911 New Industrial Trust Building, Providence, R. I.  
Dr. med. E. Schluter (prominent eye specialist),  
Hamburg, Mundsburgerdamm 11, Germany

It has come to our attention that certain parties not connected with Dr. Bates in any way are desirous of publishing a periodical called "Better Eyesight." We wish to say that any such use of this title is not with the permission of Dr. Bates or the Central Fixation Publishing Company and that any magazine issued under this title, other than the present one, is not published in the interests of the Bates Method. The title "Better Eyesight" is protected against illegal usage.

---

After June, it will be necessary to raise the price of bound volumes of "Better Eyesight." They are now listing at \$3.00 per volume and begin with the year 1923. They contain much valuable information and we would suggest that subscribers secure any volume or volumes which they may desire before the price is raised.

---

We desire to inform our subscribers that the "Better Eyesight" magazine will be discontinued after the June, 1930, issue. This will enable Dr. Bates and Mrs. Bates to devote more time to the writing of new books on treatment alone for which there has been a very great demand during the past year. We request that all those who desire to be notified upon the publication of new books kindly send us their names and addresses, which will be kept on file.

## BETTER EYESIGHT

A MONTHLY MAGAZINE DEVOTED TO THE PREVENTION AND CURE OF IMPERFECT SIGHT WITHOUT GLASSES

JUNE, 1930

Final Magazine Issue

### Stop Staring

It can be demonstrated by tests with the retinoscope that all persons with imperfect sight stare, strain, or try to see. To demonstrate this fact:

+Look intently at one part of a large or small letter at the distance or near-point. In a few seconds, usually, fatigue and discomfort will be produced, and the letter will blur or disappear. If the effort is continued long enough, pain may be produced.

To break the habit of staring:

(1) Shift consciously from one part to another of all objects regarded, and imagine that these objects move in a direction contrary to the movement of the eye. Do this with letters on the test card, with letters of fine print, if they can be seen, and with other objects.

(2) Close the eyes frequently for a moment or longer. When the strain is considerable, keep the eyes closed for several minutes and open them for a fraction of a second—flashing. When the stare is sufficient to keep the vision down to 2/200 or less, (most unclear) palm for a longer or shorter time; then look at the card for a moment. Later mere closing of the eyes may afford sufficient rest.

(3) Imagine that the white openings and margins of letters are whiter than the rest of the background. Do this with eyes closed and open alternately. It is an interesting fact that this practice prevents staring and improves the vision rapidly.

## Imagination Essential to Sight

By W. H. BATES, M.D.

IT IS a well-known fact that vision is a process of mental interpretation. The picture which the mind sees is not the impression on the retina, but a mental interpretation of it. To the mind objects seen appear to be in an upright position, but the picture on the retina is upside down. When the sight is normal the margins and openings of black letters on a white card appear whiter than the rest of the card, but this, of course, is not the fact, the whole background being of the same whiteness. One may seem to see a whole letter all alike at one time, but, as a matter of fact, the eye is shifting rapidly from one part to another. The letter may also seem to move although it is stationary.

When the vision is imperfect the imagination is also imperfect. The mind, in short, adds imperfections to the imperfect retinal image. A great part of the phenomena of imperfect sight are, therefore, imaginary and not in any way to be accounted for by the derangement of the visual apparatus. The color, size, form, position and number of objects regarded are altered, and non-existent objects may be seen. Some persons with imperfect sight literally see ghosts. A boy, or a grown person either, in a dark cellar, is often under such a strain that he thinks he sees sheeted figures, and one of my patients, in broad daylight, used to see little devils dancing on the tops of high buildings.

It is a great relief to patients to learn that these appearances are imaginary, and helps them to bring the imagination under control. And as it is impossible to imagine perfectly without perfect relaxation, any improvement in the interpretation of the retinal images means an improvement in the conditions which have led to a distortion of those images; for relaxation, as all regular readers of this magazine know, is the cure for most eye troubles. There is no more effective method of improving the sight, therefore, than by the aid of the imagination, and wonderful results have been obtained by this means. At times imagination almost seems to take the place of sight, as in the case of a patient who gained a high degree of central fixation in spite of the fact that the macula (center of sight) had been destroyed, or in those cases in which patients become able to imagine correctly letters which are seen only as grey spots without knowing what they are.

Memory, Imagination of letters on the Eyechart produces clear vision

How patients manage to see best where they are looking without a macula is hard to explain, but the imagination of letters which are not consciously seen is probably made possible by a certain degree of unconscious vision. When one looks at a letter on the Snellen test card which can be seen distinctly and tries to imagine the top straight or open when it is curved, or curved when it is straight or open, it will be found impossible to do so, and the vision will be lowered by the effort, to a greater or less degree. In one case the mere suggestion to a patient that he should imagine the top of the big C straight caused the whole card to become blank. When one looks at a letter seen indistinctly without knowing what it is and tries to imagine it to be other than it is, one is usually able to do so, but not without strain, evidenced by the fact that the letter becomes more blurred, or by the impossibility of imagining

that it has a slow, easy swing of not more than a quarter of an inch. This fact makes it possible to find out what the letter is without seeing it.

The patient begins by imagining each of the four sides of the letter taken in turn to be straight, curved, or open, and observing the effect of each guess upon the swing. If the right side is straight, for instance, and he imagines it to be straight, the swing will be unchanged; but if he imagines it to be curved, the swing will be lengthened or lost, or will become less even and easy. If he is unable to tell the difference between two guesses it is because the swing is too long, and he is told to palm and remember a letter of diamond type, with its short swing, until he is able to shorten it. Having imagined each of the four sides of the letter correctly, he becomes able to imagine the whole letter, first with the eyes closed and covered, and then with the eyes open.

When one knows what the four sides of a letter are, its identification, in some cases, is a simple process of reason. A letter which is straight on top and on the left side, and open on the two other sides, cannot be anything but an F. If, on the contrary, it is straight on the bottom and on the left side, and open on the other two, it must be an L. Such letters can be imagined with a lower degree of relaxation than the less simple ones, like a V, a Y, or a K. If the letter is not imagined correctly, the swing will be altered, and in that case the process should be repeated from the beginning.

Having imagined the letter correctly, the patient is told to imagine it first with the eyes closed and covered and then with the eyes open and looking at the card, until he is able to imagine it as well when looking at the card as when palming. In this way it finally becomes possible for him to imagine it so vividly when looking at the card that he actually sees it.

With most patients this method of improving the sight produces results more quickly than any other. Others, for some unknown reason, do not succeed with it. Temporary improvement is often obtained in an incredibly short space of time, and by continued practice this temporary improvement becomes permanent.

The patient who describes her case later on in this article looked at the Snellen test card at ten feet one day, and did not see any of the letters, even as grey spots. By the method described above she became able in half an hour to read the whole card. A little girl of ten could not see anything at ten feet below the large letter at the top of the card. She was told how to make out the letters by the aid of her imagination, and then left alone for half an hour. At the end of this time she had read the whole of an unfamiliar card. A child of about the same age whose left macula had been destroyed by atrophy of the choroid (middle coat of the eye) was able with the affected eye to see only the 200 letter, on the test card, and that only when she looked to one side of the card. She was treated by means of her imagination, and after a few months, during which time she came very irregularly, she obtained normal vision in both eyes. She is still under treatment.

A school girl of sixteen with such a high degree of myopic astigmatism that she could see only the large letter at ten feet became able in four or five visits, by the aid of her imagination, to read 20/20 temporarily, and at her last visit she read 20/15 temporarily. A college student twenty-five years old, with compound hypermetropic astigmatism (four diopters in each eye), could read only 20/100 with his right eye and 14/200 with his left, and had been compelled to stop his studies because of the pain and fatigue resulting from the use of his eyes at the near-point. In four visits his vision was improved by the aid of his imagination to 20/30 and he became able to read diamond type at six inches without glasses and without discomfort.

These and many other cases of the same kind have demonstrated that imagination is necessary to normal sight.

## A Patient's Report

I began to wear glasses for shortsight when I was fifteen, and from that time I wore them constantly until I came to Dr. Bates. For the last two or three years I never took them off, except for close work, until I got into bed at night, and before I got out of bed in the morning I put them on again.

In spite of these precautions my sight became steadily worse, and for the last ten years I have spent my time and money going from one specialist to another both in this county and in Europe. Three of the most famous specialists in Switzerland told me that I had retinitis pigmentosa, a condition in which pigment is deposited in the retina, and which, I was told, always ended in complete blindness if the patient lived long enough. Nothing could be done to prevent this outcome, they said, but they advised me to wear dark glasses when I went out of doors on bright days, because by exposing my eyes to strong light I was spending my capital. For the last three years I did this, and for the last year, on very sunny days, I often wore dark glasses in the house also, because my eyes had become so sensitive to the light that I could sometimes find relief only by going into a darkened room. Even with dark glasses and drawn blinds, there was a kind of razzle-dazzle before my eyes which was so maddening that I almost longed for the blindness with which I had been threatened, so that I might be free from such distresses. When I looked out of a window onto a sunny street and then back into the room again, everything became perfectly black for a minute. For the last two years and a half I have not been able to go out alone in the city.

In this state of utter hopelessness, with my sight rapidly getting worse, I heard of Dr. Bates through a patient whom he was treating, and, in spite of what I felt to be the incredulity of my friends, although they were considerate enough not to express it, I lost no time in consulting him. The unusualness of his methods, while it excited the suspicion of others, was a recommendation to me. I knew what the old methods accomplished, or rather what they did not accomplish, and I wanted something different. It seemed to me that Dr. Bates was the very man I had been looking for.

My friends have now been converted, but, in spite of the fact that I am able to report substantial improvement in my vision, I still meet with much skepticism in other quarters. A doctor to whom my progress was reported by a friend wrote to her that if my trouble were imaginary Dr. Bates might help me through hypnotism or mind cure, but that if there were anything really the matter with my eyes he could do nothing by his methods. One who had met some of Dr. Bates' cured patients and, was inclined to believe in him, said, when, told that I was being treated for retinitis pigmentosa:

"Good gracious, he surely doesn't pretend to cure retinitis pigmentosa! That is an organic disease."

I said that he not only pretended to cure it, but had made substantial progress in my case. The doctor said:

"I think he'll help you, but I don't believe you are ever going to see without limitations."

The improvement in my vision since I have been under treatment has been indisputable. After two weeks the intangible suffering caused by light left me, and it has never returned. I can go out in the brightest sunlight without glasses of any kind, and, although my eyes feel weak and I squint a little, there is no real distress. I can look out of a window onto a sunny street, and when I turn back again into the room there is no blindness. When I first took off my glasses I had to bend over close to my plate when I was eating, in order to see what was on it. Now I sit in an almost normal position, with such a slight bend that I don't think anyone would

notice it. I also operate a typewriter while sitting in a normal position. For three years it has been very difficult for me to read or sew, with or without glasses. Now I do both without glasses, and instead of the distress which these activities formerly caused me, I experience a delightful feeling of freedom. And not only can I read ordinary print, but I can read diamond type and photographic reductions. About a year ago I began to lose my color perception, and up to two weeks ago I was unable to distinguish the rug from the floor in the doctor's office. Now I can see that the floor is red and the rug blue, tan and black. At the present writing I have just become able to observe that a couch cover in my apartment, which had always appeared blue to me, is green. I am still unable to see very much at the distance. But I am beginning to make out the features of the people around me and to read signs in the streets and street-cars, and when I look out of the windows on the Subway I see the people on the platforms. My field is still very limited, but I am conscious that it is slowly enlarging. The other day I pinned a piece of paper three inches from the test card, and was able to see it while looking at the card. After such improvement, in the brief period of five weeks, I do not feel inclined to credit the prediction of my medical friend that I am going to regain my sight only with limitations. I hope I am going to get normal vision.

Along with the improvement in my sight there has come also a remarkable improvement in my physical condition, the natural result of freedom from suffering. I used to be a very restless sleeper, and when I woke in the morning I was greatly fatigued. Now the bed is as smooth in the morning as if I had never stirred all night, and I am much more refreshed than I used to be, although not so much so as I hope to be later. Formerly I had to force myself to write a letter. Now it is a pleasure to do so, and I am clearing off all my correspondence. I could not attend to my accounts. Now I have them all straightened out. If I could receive nothing more from the treatment than this physical comfort and increased ability to do things, it would be worth while.

## Suggestions

By EMILY A. BATES

- 1. If the vision of the patient is improved under the care of the doctor, and the patient neglects to practice, when he leaves the office, what he is told to do at home, the treatment has been of no benefit whatever. The improved vision was only temporary. Faithful practice permanently improves the sight to normal.**
- 2. If the patient conscientiously practices the methods, as advised by the doctor, his vision always improves. This applies to patients with errors of refraction, as well as organic diseases.**
- 3. For cases of squint we find that the long swing is beneficial to adults and to children.**
- 4. When a patient suffers with cataract, palming is usually the best method of treatment, and should be practiced many times every day.**
- 5. All patients with imperfect sight unconsciously stare, and should be reminded by those who are near to them to blink often. To stare is to strain. Strain is the cause of imperfect sight.**
- The following rules will be found helpful if faithfully observed:—**
- 6. While sitting, do not look up without raising your chin. Always turn your head in the direction in which you look. + Blink often.**
- 7. Do not make an effort to see things more clearly. If you let your eyes alone, things will clear up by themselves.**
- 8. Do not look at anything longer than a fraction of a second without shifting.**
- 9. While reading, do not think about your eyes, but let your mind and imagination rule.**
- 10. When you are conscious of your eyes while looking at objects at any time, it causes discomfort and lessens your vision.**
- 11. It is very important that you learn how to imagine stationary objects to be moving, without moving your head or your body.**

When the eyes move, shift, stationary close objects appear to move in the opposite direction. Distant objects appear to move with the eyes in the same direction. Practice seeing this with the eyes open and in the imagination with the eyes closed.

Moving the head and body with the eyes when shifting is the normal function of the visual system and improves/perfects shifting, central fixation, appearance of oppositional movement, keeps the neck, head, eyes relaxed, mobile and vision clear. When shifts are very small, tiny, the head movement may be very small or not occur but the head, neck, eyes remain relaxed, loose.

- 12. Palming is a help, and I suggest that you palm for a few minutes many times during the day, at least ten times. At night just before retiring, it is well to palm for half an hour or longer.**

## Questions and Answers

Q—(1) Should a house be brightly lighted by a direct electric light or a reflected white light?

(2) In many homes colored shades are used on the lights. Does that impair the sight? C. I. I.

A—(1) The more brightly the house is lighted the better for the sight.

(2) Yes. Avoid all forms of fluorescent lights.

Q—(1) Is it advisable to use specimens of diamond type other than the "Seven Truths of Normal sight?" Would it be well to get a New Testament in diamond type?

(2) I have thus far found the flashing method the most helpful. However, after closing the eyes, I have difficulty in opening them. The lids seem to stick together, as it were. What is the cause of such stickiness and the remedy?

(3) I was trying to read the "Seven Truths" lately by the flashing method, and for about twenty minutes obtained very little results.

Then, all of a sudden, upon closing my eyes, I saw the blackest object I have ever seen with closed eyes. I was startled, it seemed so real, and on opening my eyes I was surprised to find that I could read practically all of the "Seven Truths" clearly, at thirteen inches, without closing my eyes. I think the black object was probably the black rubber key of the electric socket in the fixture which I had unconsciously looked at from time to time during the exercise. I have not been able to do just this since. What is the probable reason for my failure?

(4) I find I see any reading matter more clearly in a bright light—sunlight or electric light—than in a dim or less bright light. Why is this?

(5) Today in trying to read the "Seven Truths" I found that I could do it at six or seven inches with few alternate closings of the eyes; but I found in accomplishing this I was partially closing my eyelids, (squinting) so that I must have looked much like the Patagonians in Fig. I in Dr. Bates' book, said to be probably myopic when the picture was taken. I found that I could not keep my eyes thus partly closed without some strain, but I could not see the print clearly when they were wide open. Often the print would look quite blurred when I first looked at it, but it cleared perceptibly and became quite black as I continued to look. I also found myself reading today twenty pages of fairly small print at about eight or nine inches in much the same way. W. C. C.

A—(1) Yes, if you wish to. The "Testament" would be a good thing to have.

(2) Difficulty in closing or opening the eyes is a common symptom of strain, and may be relieved by any method that relieves strain.

(3) Such intervals of relaxation are a very common phenomenon. They will come more frequently and last longer if you continue to practice.

(4) In a bright light the contrast between black letters and their white background is more marked than in a dim light. Persons differ greatly, however, in the amount of light they require for maximum vision. Some people see better in a dim light, because they think that condition a favorable one.

(5) It is a bad one.

## Announcements

Space does not permit us to print the entire list of Dr. Bates' authorized representatives in the United States, Canada and Europe, which we should like to do for the benefit of our subscribers. The following, however, is a list of those who have taken courses of instruction in the Bates Method within the past few months. Those subscribers who wish to know if there is an authorized representative in their city may obtain this information by writing direct to Dr. Bates at 210 Madison Avenue, New York City.

Miss Clara M. Brewster  
Studio 6, Aquila Court,  
Omaha, Nebraska.

Mr. Fred Baechtold,  
572 12th St.,  
West New York, N. J.  
Tel.—Palisade 6-7735

Miss Mary E. Wilson,  
2538 Charming Way,  
Berkeley, Calif.

Mr. Harold E. Ensley,  
112 West 104th St.,  
New York City.

Dr. Paul J. Dodge,  
911 New Industrial Trust  
Bldg., Providence, R. I.

Dr. Med. E. Schluter,  
Hamburg, Mundsburger-  
damm 11, Germany.

Mrs. D. L. Corbett,  
1712½ Fifth Ave.,  
Los Angeles, Calif.

Mrs. R. Norman Jolliffe,  
171 West 71st St.,  
New York City.

Miss Jane Button,  
249 Harvey St.,  
Germantown, Pa.

It has come to our attention that certain parties not connected with Dr. Bates in any way are desirous of publishing a periodical called "Better Eyesight". We wish to say that any such use of this title is not with the permission of Dr. Bates or the Central Fixation Publishing Company and that any magazine issued under this title, other than the present one, is not published in the interest of the Bates Method. The title, "Better Eyesight", is protected against illegal usage.

As we have already notified our subscribers, "Better Eyesight" is being discontinued with this issue. This will enable Dr. Bates and Mrs. Bates to devote more time to the writing of new books on treatment alone for which there has been a very great demand. We request that all those who desire to be notified upon the publication of new books kindly send us their names and addresses which will be kept on file.

Bound volumes of "Better Eyesight" containing the issues from July, 1929 to June, 1930, inclusive, will be ready about July 15th. Those subscribers wishing to have their own magazines bound may send them to us before July 10th and they will be bound at the same time our issues are being bound. The price for binding will be \$1.00.

## DR. BATES SUNLIGHT TREATMENTS (As described in Better Eyesight Magazine)

Shining direct sunlight on the sclera, the outer white part of the eye is a old treatment Dr. Bates applied to bring life, health, activity to the retina and its cells, cones, rods, nerves, blood vessels. Dr. Bates cured unclear vision and other eye problems, diseases with this treatment. People that were blind or almost blind would begin to see light and obtain clear vision as result of this treatment and other Bates activities.

### Directions

**1 - Face the sun with the eyes pupil directed away from the sun.** Allow full spectrum sunlight to shine directly on the sclera, (white part of the eye) by pulling the upper eyelids up while looking down. The sun shines on the upper white area of the eye. The eyes pupil is down, under the lower eyelid to prevent direct sunlight from shining into the pupil.

Move the eyes and head/face side to side to move the sunlight over the entire sclera and retina, lens through the sclera. Keep the sunlight moving on the sclera for a few seconds. Then stop, rest. Repeat if comfortable. Do not overdo it. Movement of the eyes, light places sunlight on all areas of the eye, retina, improves absorption, use of the light, activation of the retinas cells, light receptors... and prevents overexposure, concentration of the light, sunburn on the eye.

When pulling the eyelid; do not touch the eye or eyelid. Pull on the skin above the eyelid. Keep fingernails very short. Wash your hands first. Avoid chemical based soap. Do both eyes at the same time; left thumb pulls left lid, right thumb pulls right lid. Pull gently. This treatment also helps the eye build normal tolerance to sunlight, improves health and color of the sclera, perception of light, color, clarity of vision.

**2 - Now, direct the sunlight onto the bottom of the sclera; Pull the lower eyelids down, move the eye/pupil up in the opposite direction** so the sun shines on the lower area of the sclera and not directly into the pupil.

Move the eyes, head/face side to side. Keep the sunlight moving on the sclera for a few seconds. Then stop, rest. The head/body may need to be tilted back a bit to keep sunlight on the lower sclera and away from the pupil. Practicing this treatment repeatedly can tense the eye muscles and the pull of the fingers can irritate the eyelids, skin. Use it occasionally.

#### Sunlight on the Sclera

Face the sun,  
the eyes pupil directed away  
from the sun.

**1 - Pull the upper eyelid up and look down.**  
Sunlight shines on the upper area of the Sclera.  
Sunlight does not shine into the pupil.

**2 - Pull the lower eyelid down and look up.**  
Sunlight shines on the lower area of the Sclera.  
Sunlight does not shine in the pupil.

Expose left and right eyes to the sun at the same time.  
Move the eyes left and right enabling the sun to shine/move on all areas of the Sclera.

### Sun-Glass Treatment

Dr. Bates cured advanced eye problems, blindness by the sunlight methods and, also applying the use of the Sunglass to increase the strength of the sunlight on the eyes sclera and retina through the sclera. He moves the sunlight through the Sunglass quickly over the sclera for only a second, few seconds. He also moves the sunlight through the Sunglass on/over closed eyelids. Light is not directed into the pupil.

The light is kept in movement and moved quickly on the sclera and not for too long; only a few seconds in order to prevent over concentrating sunlight on any one or more areas of the eye, to prevent overexposure, sunburn on/in the eye. Distance of the glass must be correct or the eye can be burned.

The patient is exposed to plain sunlight first, without the glass to get the eyes adjusted to the light before using the sun-glass.

Do not do this at home without an eye doctor's direction. Done incorrect, it can burn the eye.

## THE USE OF THE SUN GLASS

In using the sun glass, it is well to accustom the eyes of the patient to the strong light by having him sit in the sun with his eyes closed, and at the same time he should slowly move his head from side to side, in order to avoid discomfort from the heat. Enough light shines through the eyelid to cause some people a great deal of discomfort at first, but after a few hours' exposure in this way, they become able to gradually open their eyes to some extent without squeezing the lids. When this stage is reached, one can focus, with the aid of the sun glass, the light on the closed eyelids, which at first is very disagreeable. When the patient becomes able to open the eyes, he is directed to look as far down as possible, and in this way the pupil is protected by the lower lid. Then by gently lifting the upper lid, only the white part of the eye is exposed, while the sun's rays strike directly upon this part of the eyeball. The sun glass may then be used on the white part of the eye. Care should be taken to move the glass from side to side quickly. The length of time devoted to focusing the light on the white part of the eye is never longer than a few seconds. After such a treatment the patient almost immediately becomes able to open his eyes widely in the light.

Most Modern Natural Eyesight Improvement Teachers do not apply the Sunglass Treatment - (Mainly due to fear of the AMA.) Ophthalmologist Bates cured many vision problems, eye diseases, various types of blindness with the Sunglass and Sunlight, Sunning Treatments. Try plain Sunning, Sunlight first.

the Sunglass light is on the eyes.

Start with eyes closed, look far down. Bring the glass, light beam close, but a safe distance from the eye. Move the light beam on the white area of the eye through the eyelids. The movement helps to prevent too much heat. Test the intensity of the light, heat, distance of the glass... on the closed eyelids first. See the size of the light spot on the eye and the blood vessels... in the eyes sclera, retina. Keep the light moving, move it quickly on the sclera for a few seconds.

Then, repeat with the eyes open: still looking far down, eyes pupil under the lower eyelid, protected from the light; lift the upper eyelid, open the eyes and move the light quickly side to side, a few seconds on the white area, sclera of the eye. Then repeat the steps with the other eye.

The Sunglass is a glass. As described in other chapters; All glass, plastic.; eyeglasses, windows, sunglasses block out part of the sun's light spectrum causing unhealthy partial spectrum, unbalanced light to exit the glass and shine into the eyes, travel to the brain, body. This impairs health, function of the brain, body, eyes and clarity of vision. For this reason the sunglass is only used to get the cells, light receptors, capillaries... in the eye, retina, lens back to full life, activity, bring the vision back. Then the glass is not used. Plain sunlight not passing through glass is used by practicing Sunning, Sun-gazing... as described in this chapter.

Read more directions for Sunning, Sun-Gazing, Sunglass Treatments in the PDF Natural Eyesight Improvement E-book; Ophthalmologist Bates 'Better Eyesight Magazine' describes this treatment. See; Better Eyesight Magazine; April, May, June, August, October, December, 1926 and November, 1924 and

**The Sunglass Treatment** is be done by ■ Bates Method Experienced Ophthalmologist and only if necessary in cases of blindness, extreme vision impairment and only after closed eyes sunning, daily sunlight exposure; eyes open (not staring into the sun), yes; looking at, shifting on the bright sunny sky, clouds, trees and other Bates Method Treatments have been tried first.

If these have not brought vision improvement, the Sunglass Treatment may.

Be aware that certain types of glass act as a magnifying glass. The Sunglass is a magnifier and sunlight passing through the Sunglass can burn the eye.

Only a professional should apply this method;

The glass is never still; the glass is moved continually side to side causing the light to move quickly on the white area of the eye. A short time; only a few seconds of light is placed on the eye. Do one eye at a time.

(Patch the eye not being worked upon with a thick white eyepatch to prevent the eye, pupil from moving into the light of the Sunglass. Keep the patch open on the outer side away from the glass to allow plain daylight into that eye to keep both brain hemispheres, eyes active. Do not wear any type of eyeglasses, contact lenses, sunglasses, tinted, UV blocking lenses when using the Sunglass, Sun-gazing, Sunning.)

Distance of the glass from the eye must be exact, a specific distance and the time the light is on the eye (white area, sclera only, through or under eyelids) must be brief, few seconds or the eye can be burned. It is a certain type of magnifying glass; Type, size, thickness, curvature... of the glass, distance, angle from the eye, strength of the sun affects the strength, intensity, concentration of the light ray beam, heat of the sunlight through the glass. The heat increases with the amount of time the light is on the eye. The correct amount is relaxing, healthy for the eye. The light must never shine on/into the eyes pupil. Keep the light away from the pupil, iris. Keep the eye, pupil far down, under the lower lid to prevent the light beam from shining into the pupil. Do not move the eyes when

other 'Use of the Sunglass, Burning Glass' articles. Better Eyesight Magazine article June, 1926 in original form is shown on this page.

I place the instructions here due to the many cures Dr. Bates, Emily Lierman, Bates, other doctors obtained with the Sunglass and to enable persons to know if their Eye doctor is doing the treatment correct, safe.

**Sun-Gazing;** Looking into the sun with the eyes open, while moving the eyes, head/face side to side, keeping the eyes, head/face in movement 'shifting' is still done by some people in various countries, cultures.

For sun-gazers that do look at the sun with the eyes open; Practice only for 5-10 seconds occasionally, always moving the head/face, eyes; shifting side to side, top and bottom... across the sun. Blink often.

Never stare into the sun. Application time may vary with certain cultures, countries, treatments by experts.

Avoid areas where the sunlight is concentrated or the ozone layer is depleted.

Looking at the sun at sunrise, sunset in safe areas of the planet is allowed as long as staring, over-exposure is avoided. People have been looking at the sky, sunrise, sunset for millions of years.

Due to the depletion of the ozone layer, Modern Bates Teachers do not advise looking into the sun with the eyes open. **Closed Eyes Sunning only is practiced.**

Looking at the bright areas of the sky, clouds, tree tops with the eyes open on a sunny day is allowed.

**Never look at or near the sun during a solar eclipse of the sun.**

Good nutrition is necessary to maintain the eyes natural protection and tolerance to sunlight.

Sunlight through the eyes and on the skin is also necessary for the body to absorb, create, function with nutrients, vitamins, vitamin D, calcium., minerals, to help protect the eyes, skin from sunburn, overexposure to sunlight, to produce, balance, control hormones, chemicals in the brain, body, body organs, systems, including melatonin for a normal sleep cycle and serotonin, tryptophan... for a positive state of mind, good mood, positive thoughts, emotions. The eyes need sunlight to remain healthy, keep the vision clear.

Most drugs and some herbs impair the vision, eye health, natural tolerance, protection from over-exposure to sunlight.

**Sunlight contains all colors, frequencies, energy of the light spectrum.**

**5. SUN TREATMENT.** The eyes need sunlight. People who work in mines, where there is no sun, sooner or later develop inflammations of the interior of the eyes. The cloudiness of the lens from cataract is lessened by exposing the eye to the direct rays of the sun. When using the sun treatment, it is best to let the eyes become accustomed to the sun by mild treatment at first. Have the patient sit in a chair with his eyes closed and his face turned toward the sun. He should slowly move his head a short distance from side to side. The movement of the head prevents concentration of the sun's rays on one part of the eye. After some days of treatment, or when the patient becomes more accustomed to the light, one may use the sun-glass with added benefit. Direct the patient to look far down and while he does this, lift the upper lid gently, exposing to view the sclera or white part of the eye. Now, with the aid of the sun-glass focus the sunlight on the forehead or on the cheek, and then rapidly pass the concentrated light over various parts of the sclera. This requires less than a minute of time. It is

not well to be in a hurry. One should wait until the patient becomes sufficiently accustomed to the sun to permit the upper eyelid to be raised while he looks far down, exposing the sclera only. It is important that the patient be cautioned not to look directly at the sun.

### Prognosis

The cure of cataract is usually accomplished more quickly than the cure of some other diseases of the eye. My assistant, Emily C. Lierman, has had unusual success in treating cataract cases, as she adapts my methods to each individual case. In her book, "Stories from the Clinic," the treatment is described in detail.

## PALMING

### PALMING

TO COVER THE CLOSED EYES WITH THE PALMS OF THE HANDS WHILE RELAXING AND THINKING SOMETHING PLEASANT.

THIS PICTURE SHOWS THE LEFT AND RIGHT HANDS/EYES OF A PERSON FACING THE READER. TO SEE HOW THE READER'S HANDS ARE PLACED: VIEW THIS PICTURE IN A MIRROR OR PLACE THE PICTURE OUTWARD ON THE CHEST AND LOOK DOWN AT THE PICTURE FOR A SECOND.

PALMING RELAXES THE MIND, BODY, NECK, EYE MUSCLES, EYES, AND WHEN COMBINED WITH SUNNING IMPROVES THE EYES/RETINA, BRAIN AND BODY'S ACTIVATION/REACTION TO SUNLIGHT AND ABSORPTION. USE OF SUNLIGHT. THIS IMPROVES FUNCTION, HEALTH OF EYES, BRAIN, BODY.

## THE LONG SWING

### THE LONG SWING

TURN AND SWING  
RIGHT

CENTER

TURN AND SWING  
LEFT.

**SHIFTING - EYE MOVEMENT - THE EYES/VISUAL ATTENTION/CENTER OF THE VISUAL FIELD SHIFT/MOVE FROM POINT TO POINT, PART TO PART ON A OBJECT AND FROM OBJECT TO OBJECT.**

**SHIFT ON THE HOUSE, DOT TO DOT.**

**SHIFT IN ANY DIRECTION/PATTERN.**

THE DIAGRAM ABOVE SHOWS A EXAMPLE OF THE NATURAL SHIFTING PATTERN OF THE EYES.. NOTICE THE EYES MOVE FREELY ON THE HOUSE IN A VARIETY OF PATTERNS, DIRECTIONS.

## CENTRAL FIXATION

BIRD IS SEEN CLEAR BY  
PLACING IT IN THE CENTER  
OF THE VISUAL FIELD

When looking at the bird;

Place it in the center of the visual field.

Shift part to part on the bird, moving the exact center of the visual field part to part.

Do this for any object the eyes look at; shift part to part on the object. Blink, relax.

Move the head/face, body with the eyes, in the same direction.

The center of the visual field moves with the eyes from object to object, part to part.

Use perfect, exact central fixation; shift small point to small point on objects and small parts of objects.

## SUNNING

## MEMORY AND IMAGINATION – CLEAR MENTAL PICTURES

REMEMBERING, IMAGINING OBJECTS CLEAR IMPROVES FUNCTION OF THE BRAIN WITH THE EYES AND CLARITY OF VISION.

EYES OPEN  
APPLE SEEN UNCLEAR.  
APPLE IN MIND,  
IMAGINATION IS CLEAR.

1

REMEMBER, IMAGINE THE  
APPLE CLEAR.  
SHIFT FROM PART TO PART  
ON THE UNCLEAR APPLE  
AND REMEMBER, IMAGINE  
THE APPLE CLEAR.

EYES CLOSED  
APPLE IN MIND,  
IMAGINATION IS CLEAR.

2

SHIFT FROM PART TO PART ON  
THE APPLE IN THE MIND,  
IMAGINATION AND REMEMBER,  
IMAGINE THE APPLE CLEAR.

EYES OPEN  
APPLE IS SEEN CLEAR  
APPLE IN MIND,  
IMAGINATION IS CLEAR.

3

SHIFT FROM PART TO PART ON THE APPLE  
AND REMEMBER, IMAGINE AND SEE THE  
APPLE CLEAR.  
REPEAT STEPS # 1,2,3.

USE THE IMAGINARY NOSEFEATHER WITH STEPS # 1,2,3. (SEE NOSEFEATHER, CHAPTER --)

REMEMBER, IMAGINE, SEE THE APPLE CLEAR WITH THE EYES OPEN, CLOSED, OPEN WHILE SHIFTING FROM PART TO PART ON THE APPLE WITH THE NOSEFEATHER. TRACE AROUND THE EDGES OF THE APPLE, STEM, LEAF WITH THE END OF THE FEATHER. TRACE SMALL PARTS OF THE APPLE.

PRACTICE STEPS # 1,2,3 WITH BOTH EYES TOGETHER, THEN ONE EYE AT A TIME, THEN BOTH TOGETHER AGAIN.

PRACTICE ON ANY SIZE OBJECT; LARGE, MEDIUM, SMALL, TINY AT CLOSE, MIDDLE, FAR DISTANCES.

Remembering, imagining any pleasant object, scene, happy memory, fantasy relaxes the mind, body, eye muscles, eyes resulting in clear vision.

Remembering, imagining the objects, scene clear while relaxed, easy, without effort improves the clarity of vision.

If the boy remembers, imagines a different object, any happy memory, image, scene (playing baseball, a favorite adventure...) with the eyes open looking at the apple, shifting on it and when the eyes are closed shifting on the imaginary image: when the eyes are opened - the apple will be seen clear. He can remember, imagine the apple or any pleasant object clear, shift on it in his mind and the apple will be seen clear.

Palming with the eyes closed combined with the memory imagination activity brings clear vision.

## Sunning Examples

Face the sun with the eyes closed and move the head/face slowly, relaxed side to side; left, right, left, right... Feel and see the sun move across the face/closed eyes. Then, move the head/face up and down, then circular; trace around the sun counter clockwise, clockwise. The eyes, head/face (and body) move together, at the same time, in the same direction.

Rock left and right

Do the rock while sunning; Face the sun with the eyes closed and rock the entire body side to side, left and right. Do the long swing.

Sit facing the sun, relax, eyes closed and daydream pleasant thoughts. Occasionally move the head/face side to side.

THE FINGER-TIPS OF THE 3RD FINGER OF THE LEFT AND RIGHT HANDS TOUCH WITH THE PALMS FACING IN TOWARD THE FACE. THIS IS THE START POSITION AT THE CENTER OF THE FIGURE EIGHT.

START IN THE CENTER

FRONT VIEW

DRAW THE FIGURE EIGHT WITH THE EYES, HAND AND END OF THE NOSE/FEATHER WHILE DOING THE LONG SWING. FOLLOW THE ARROWS - START IN THE CENTER AND DRAW UP THE CENTER AND TO THE LEFT FIRST. DRAW THE LEFT SIDE AND BACK UP THE CENTER. THEN DRAW THE RIGHT SIDE. DRAW: LEFT, RIGHT, LEFT, RIGHT.

DRAW THE LEFT SIDE FIRST WITH THE LEFT HAND. SWING, TURN LEFT AND LIFT THE HEEL OF THE RIGHT FOOT. EYES LOOKING AT SHIP END ON AND MOVING WITH THE CENTER FINGER-TIP OF THE LEFT HAND AS THE HAND DRAWS THE EIGHT. THE END OF THE NOSE/FEATHER AND EYES (VISUAL ATTENTION) ARE ON AND MOVING WITH THE LEFT HAND'S CENTER FINGER-TIP. PALM OF HAND IS FACING IN TOWARD THE FACE WHEN IN THE CENTER, THEN MOVES OUT STRAIGHT WITH THE ARM AS THE HAND DRAWS THE LEFT SIDE.

LOOKING, MOVING LEFT WHEN DRAWING THE LEFT SIDE ACTIVATES THE RIGHT BRAIN HEMISPHERE AND CLEAR DISTANT VISION

DRAW THE RIGHT SIDE WITH THE RIGHT HAND. SWING, TURN RIGHT AND LIFT THE HEEL OF THE LEFT FOOT. EYES LOOKING AT SHIP END ON AND MOVING WITH THE CENTER FINGER-TIP OF THE RIGHT HAND AS THE HAND DRAWS THE EIGHT. THE END OF THE NOSE/FEATHER AND EYES (VISUAL ATTENTION) ARE ON AND MOVING WITH THE RIGHT HAND'S CENTER FINGER-TIP. PALM OF HAND IS FACING IN TOWARD THE FACE WHEN IN THE CENTER, THEN MOVES OUT STRAIGHT WITH THE ARM AS THE HAND DRAWS THE RIGHT SIDE.

BACK VIEW  
LOOK AT THE DIAGRAM AND FOLLOW THIS MOVEMENT

LOOKING, MOVING RIGHT WHEN DRAWING THE RIGHT SIDE ACTIVATES THE LEFT BRAIN HEMISPHERE AND CLEAR CLOSE VISION

MOVING BACK AND FORTH; LEFT, RIGHT, LEFT, RIGHT AND PASSING ACROSS THE CENTER OF THE EIGHT (NAIL/CENTER OF THE BRAIN AND BODY) ACTIVATES AND INTEGRATES THE LEFT AND RIGHT BRAIN HEMISPHERES. CLEAR CLOSE AND DISTANT VISION AND EQUALLY CLEAR PERFECT VISION IN THE LEFT AND RIGHT EYES.

DRAWING THE FIGURE EIGHT RELAXES AND BRINGS MOVEMENT TO THE EYES, HEAD/FACE, NECK, BACK AND BODY AND ACTIVATES CORRECT VISION HABITS. THIS ALSO IMPROVES THE CLARITY OF EYE SIGHT.

The Figure Eight - Infinity Swing

FIGURE EIGHT

THE FIGURE EIGHT

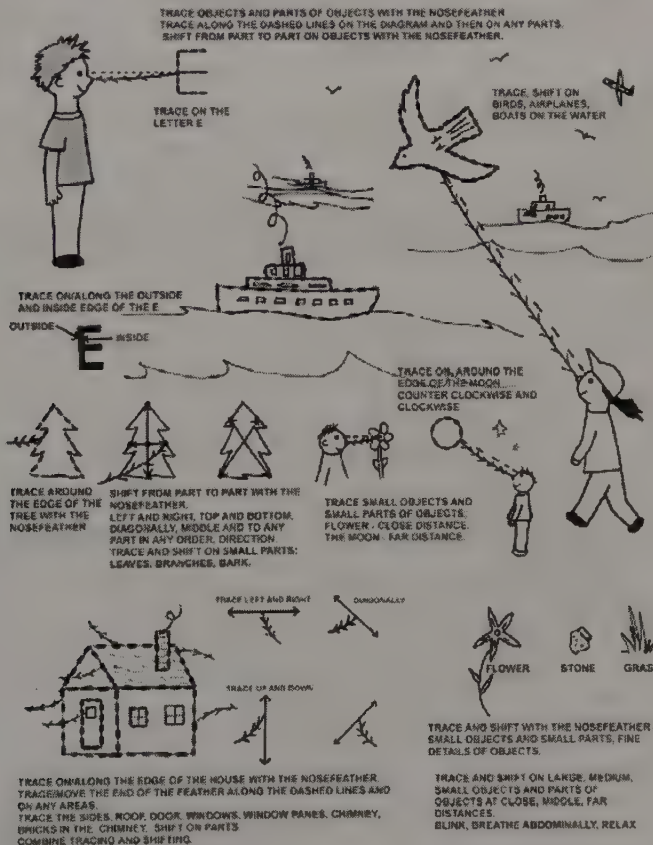

THE FIGURE EIGHT - INFINITY SWING

## THE NOSEFEATHER

THE MAN IS TRACING AROUND THE EDGE OF THE TREE WITH THE IMAGINARY NOSEFEATHER.  
THE END OF THE FEATHER EXTENDS OUT FROM THE END CENTER OF THE NOSE AND BENDS UP TO EYE LEVEL TO TOUCH THE PART OF THE OBJECT THE EYES ARE LOOKING AT IN THE CENTER OF THE VISUAL FIELD.  
THE FEATHER IS VERY THIN AND THE END FORMS A VERY SMALL POINT WHICH IS THE SIZE OF THE EXACT CENTER OF THE VISUAL FIELD PRODUCED BY THE FOVEA CENTRALIS IN THE MACULA CENTER OF THE EYE'S RETINA.  
MOVE THE POINTED END OF THE NOSEFEATHER AROUND THE EDGE OF OBJECTS AND PARTS OF OBJECTS.  
THE EYES, END OF THE NOSEFEATHER, HEADFACE AND BODY MOVE TOGETHER IN SYNCHRONIZATION SAME TIME, SAME DIRECTION.  
THE NECK IS RELAXED AND MOBILE.  
BLINK, BREATHE ABDOMINALLY, RELAX.  
THE NOSEFEATHER IS ALSO USED TO SHIFT FROM POINT TO POINT (SMALL PART TO SMALL PART) ON A OBJECT.  
THE NOSEFEATHER IS USED TO SWITCH FROM CLOSE OBJECTS TO DISTANT OBJECTS AND DISTANT TO CLOSE MIDDLE.  
THE FEATHER BECOMES LONGER WHEN LOOKING TO THE DISTANCE AND SHORTER WHEN LOOKING AT CLOSE OBJECTS.  
THE NOSEFEATHER ACTIVATES EASY USE OF CORRECT VISION HABITS; SHIFTING (EYE MOVEMENT), CENTRAL FIXATION, MOVEMENT OF THE HEADFACE, BODY WITH THE EYES, RELAXATION AND MOVEMENT OF THE NECK.  
THE FEATHER CAN BE IMAGINED AS BEING INVISIBLE.  
THIS ALLOWS THE BRAIN TO IMAGINE; REMEMBER THE OBJECT THE EYES ARE LOOKING AT CLEAR WITHOUT BEING DISTRACTED BY THE IMAGE OF THE FEATHER.

## CENTRAL FIXATION - SEE CLEAR WITH THE CENTER OF THE VISUAL FIELD

### HUMAN EYE

THE RETINA CONTAINS CONES AND RODS - LIGHT, ENERGY RECEPTORS.

CONES PRODUCE VERY CLEAR VISION - CLEARER THAN 20/20 AND BRIGHT COLOR.

RODS PRODUCE LESS CLEAR VISION (20/400) - RODS PERCEIVE GREY/BLACK/WHITE, LIGHT AND DARK BUT NO OTHER COLORS. RODS DETECT MOVEMENT OF OBJECTS IN THE VISUAL FIELD AND CONTINUE TO FUNCTION IN ALMOST COMPLETE DARKNESS.

THE FOVEA AND MACULA IN THE CENTER OF THE RETINA CONTAIN MANY CONES, (ONLY CONES IN THE CENTER OF THE FOVEA) AND PRODUCE VERY CLEAR VISION IN THE CENTER OF THE VISUAL FIELD.

THE PERIPHERAL FIELD OF THE RETINA AROUND, NEAR AND AWAY FROM THE FOVEA/MACULA CONTAINS LESS CONES AND MORE RODS, AND ONLY RODS (NO CONES) IN THE FAR OUTER PERIPHERAL FIELD.

THIS RESULTS IN LESS CLEAR PERIPHERAL VISION, THIS FAR OUTER PERIPHERAL FIELD BEING MOST UNCLEAR.

SEE CLEAR WITH CENTRAL FIXATION - A CORRECT VISION HABIT - PLACE THE OBJECT OF VISUAL ATTENTION IN THE CENTER OF THE VISUAL FIELD.

WHEN THE EYES USE THE CENTER OF THE VISUAL FIELD, THE CENTRAL RAY FOCUS PERFECT ON THE CENTER OF THE FOVEA CENTRALIS, RAYS CLOSEST TO THE CENTRAL RAY FOCUS ON THE MACULA, AND PERIPHERAL RAYS FOCUS PERFECTLY ON THE PERIPHERAL FIELD OF THE RETINA RESULTING IN PERFECT CLEAR CENTRAL VISION, CLEARER THAN 20/20 AND MAXIMUM CLARITY AND FUNCTION OF THE PERIPHERAL FIELD. THE CLARITY OF THE ENTIRE VISUAL FIELD IMPROVES.

OUTER EYE MUSCLES

RECTI - # 1, 2, 3, 4

OBLIQUE - 5, 6

The retina contains cones and rods, light receptors.  
 Cones=very clear vision, bright color.  
 Activated in light.  
 Slope functioning in almost complete darkness.  
 Rods=Less clear vision, grey, white color. Also senses movement in the visual field and continues to function in very dim light, almost complete darkness.  
 The macula contains many cones, and a few rods.  
 The fovea contains a high concentration of cones and no rods.  
 The peripheral field of the retina contains many rods and some cones with less and no cones into the far outer peripheral.  
 This is why the center of the visual field is clearest.  
 See clear by using the Macula. Fovea Centralis, center of the visual field. See much clearer, fine details, brightest color by using the fovea, exact center of the retina, visual field.  
 The center of the visual field moves with the eyes from object to object, part to part on objects keeping the vision clear.

•The Fovea centralis, center of the retina produces the exact center of the visual field, clearest vision, bright color.  
 •The Peripheral field of the retina produces the peripheral field of vision. Less clear vision, less color.

Human Eye

## Eye socket, bones, eye, eye muscles, optic nerve.

Notice that the eye socket is composed of bone segments, aligned, grown together. These are part of the skull bones. Eye muscles attach to the skull bones in the back of the eye socket. Misalignment of the eye socket or skull bones due to accidents, birth trauma, forcep, suction delivery... can mis-align the bones, place pressure, tension on/in the eye, optic nerve, eye muscles resulting in crossed, wandering eyes, imperfect convergence, divergence, accommodation, un-accommodation, unclear vision, astigmatism and other abnormal eye conditions. Special chiropractors (Cranial, Cranio Sacral Therapy, Osteopathy) can re-align the bones of the skull if needed. Often, use of the Bates method alone can correct eye function and clarity of the vision.

## EYECARTS

Letter size for the charts on the following pages are approximate; print from the PDF E-Book and resize with a copy machine for exact measurement. Print the 20/20 line  $\frac{3}{8}$  inches. When letters on that line and below are clear; vision is clearer than 20/20 for distant vision at 20 feet and farther. Print the charts small and fine print for close vision practice at 5 feet and up to 1 inch from the eyes.

Read, See Small letters Clear on a Familiar Eyechart Daily;  
Both eyes together, one eye at a time, both eyes together again.

### SNELLEN TEST CARDS

There should be a Snellen test card in every family and in every school classroom. When properly used it always improves the sight even when it is already normal. Children or adults with errors of refraction, if they have never worn glasses, are cured simply by reading every day the smallest letters they can see at a distance of ten, fifteen, or twenty feet.

*For Sale By*

### **The Central Fixation Publishing Company**

Paper .....50 Cents

Cardboard (folding) .....75 Cents

#### **DELIVERED**

Back numbers **BETTER EYESIGHT**: single copies, 30 cents; first and second years, unbound, \$3 each; bound in cloth, \$1.25 extra. Photographic reductions of the Bible, \$4. Ophthalmoscopes (best quality), \$20. Burning glasses, \$4. Reprints of articles by Dr. Bates in other medical journals, a limited number for sale. Send for list.

# EYECARTS TO TEST AND IMPROVE CLOSE AND DISTANT EYESIGHT

SWITCH AND SHIFT ON LETTERS ON TWO IDENTICAL EYE CHARTS PLACED AT CLOSE AND FAR/ CLEAR AND UNCLEAR DISTANCES.

SHIFT FROM PART TO PART (DOT TO DOT) ON THE E'S

Videos - <http://www.youtube.com/watch?v=863yFmc-Ius>

## Meaning of 20/20; (for Distant Vision)

- +The top number indicates the distance the person is standing from the chart.
- +The bottom number indicates the size of the letter, the line the eyes are looking at.  
A 20/20 letter is 3/8 inch. high.

**E** This **E** is about 3/8 inch. on 100% computer screen.

- +The bottom number also indicates the distance that a person with clear vision sees the letter clear.

**Example;** the 20/20 line on the test chart for distant vision;  
+The top number, 20 indicates; the person is standing 20 feet away from the letter on the eyechart.

- +The bottom number, 20 indicates the person is looking at the 20/20 line, 3/8 inch. letter and, that; a person with clear 20/20 vision can see the letter clear at 20 feet away.

The eyechart is placed at 20 feet to test distant vision because the eyes do not need to un-converge, un-accommodate any further when looking at about 20 feet and farther into the distance. If the letters are seen clear at 20 feet, they are seen clear at all distances beyond 20 feet.

Here's another example; 20/200;

- +The top number (20) indicates the person is standing 20 feet away from the eyechart.
- +The bottom number (200) indicates the size of the letter, line the person is looking at.

The 200 line letter is the largest letter on the top of the chart.  
A 20/200 letter is 3 1/2 inch. high.

- +The bottom number, (200) also indicates that a person with

Distant vision - Big C eyechart with a small E line added at bottom.

20 = 20 feet  
20 = 3/8 inch letter - 20 line.  
Normal, clear vision.

20 = 20 feet  
5 = Smallest letter, bottom of chart - 5 line.  
Clearer than 20/20.

40 = 40 feet  
5 = Smallest letter, bottom of chart - 5 line.  
Most clear vision, much clearer than 20/20.  
Person sees 5 line at 40 feet away.

20 = 20 feet  
200 = Largest letter, top of chart - 200 line.  
Most unclear vision for this eyechart.

5 = 5 feet  
200 = Largest letter, top of chart.  
Vision more unclear.  
The person must stand closer to the chart, at 5 feet, to see the 200 line letter clear.

20 = 20 feet  
300 = Letter larger than 200 line.  
More unclear than 20/200.  
Person cannot see the 200 line clear.  
A larger, 300 size letter is seen clear.  
The 200 and other lines might be seen clear at closer distances to the chart.

E  
A  
R

clear 20/20 vision can see the letter clear at 20 feet and up to 200 feet away.

A person with 20/200 distant vision can see the large 20/200 letter at 20 feet but cannot see it clear farther than 20 feet. It may be seen clear at closer distances.

Smaller letters below the 20/200 line are not seen clear at 20 feet and farther away.

20/200 vision is very unclear, much less clear than 20/20.

Vision can be more unclear; 20/300, 5/200... Many people with 20/200, 300 and more unclear vision have attained 20/20 and clearer vision with practice of the Bates Method.

20/40 vision is clearer than 20/200 but less clear than 20/20. 20/40 is considered legal for driving in most states. 20/40 is close to 20/20 clarity and people can function comfortably with 20/40 vision without wearing eyeglasses. 20/30, 20/25 is clearer than 20/40 and almost 20/20.

When vision is less clear than 20/40; 20/50, 70, 100... it is still best to avoid wearing eyeglasses as much as possible. Eyeglasses maintain and increase the eye muscle tension and blur. When glasses are avoided the eyes, eye muscles, mind/brain, (visual system) relax, correct vision habits are easily applied and clarity of vision improves.

Close vision is tested with smaller letters with the eyechart placed at various distances closer than 20 feet. Reading vision is tested at 3 ft. to 6 inches and closer to the eyes with small and fine print. Seeing fine print clear at 5 to 1 to 1/4 inches from the eyes is very clear vision. Healthy for the eyes.

### Relax and Shift, Blink when Reading the Eyechart. Use Central-Fixation

Does your boy squint?

This boy is reading the Snellen test card with normal vision. Note the absence of facial strain.

The same boy straining to see at a distance is producing myopic astigmatism in eyes previously normal.

In this picture the boy is making himself myopic by partly closing his eyes and making conscious effort to read the test card at ten feet.

### Immediate Production of Myopia and Myopic Astigmatism in Eyes Previously Normal by Strain to See at the Distance;

Fig 1 - Boy reading the Snellen test card with normal vision. Note the absence of facial strain.

A boy with normal eyes reading the X line of the Snellen test card at 10 feet.

Notice the expression of the eyes with the focus completely relaxed.

Fig 2 - The same boy trying to see a picture at twenty feet. The effort, manifested by staring, produces compound myopic astigmatism, as revealed by the retinoscope. Simultaneous retinoscopy indicated compound myopic astigmatism. He was unconscious of the fact that his eyes were focused for a near point. Note the manifestation of effort by staring.

Fig 3 - The same boy making himself myopic voluntarily by partly closing the eyelids and making a conscious effort to read the test card at ten feet. Functional myopia produced voluntarily by partly closing the eyelids (squinting) and making an effort to read the Snellen test card at ten feet.

**There are large and small close and distant eyecharts on the last pages of this book and in the PDF E-Book.**

It is difficult to print the exact, correct letter size from a computer. Try printing at 100% or larger.

The Big C and E charts print out on 4 separate pages, 11 x 8 1/2 inches, landscape. Tape them together after printing.

If the print is too light, darken it to dark black with a black marker.

If they print too small or large; place them in a copier and use the zoom setting to enlarge or reduce the letters until all letters are the correct eyechart size. See correct sizes listed below.

Letters on the charts can be reduced to small and fine print for testing, improving close vision and reading vision distances, 3 feet, 20, 10, 7, 6, 5, 3... inches away from the eyes.

Small charts are also provided.

The charts can be printed from the PDF E-Book with white letters on a black, blue... background. White letters are easy to see and relaxing to the eyes. Color activates, is healthy for the eyes, brain, visual system.

The reader can also create small charts as a identical copy of the big C, E charts. Place the identical copy at a clear close distance and look at the identical clear letters to strengthen the memory, imagination of the same letter on the distant chart. If preferred, use a large close and distant chart.

The Big C chart is the eyechart Ophthalmologist Bates refers to in his Better Eyesight Magazine. The large big letter E and C charts are for testing distant vision. Print the chart with correct letter size;

Fig. 43

Patient with atrophy of the optic nerve gets flashes of improved vision after palming.

**Start with the big letter E (or C) at the top of the chart - 20/200 line;**

**20/200 - 3 1/2 inch. high**

**20/100 - 1 3/4 inch.**

**20/70 - 1 1/4 inch.**

**20/50 - 7/8 inch.**

**20/40 - 11/16 inch.**

**20/30 - 1/2 inch.**

**20/20 - 3/8 inch. ----- Normal clear vision at 20 feet away.**

**20/15 - 1/4 inch. All numbers below 20/20 indicate clearer than 20/20.**

**20/10 - 3/16 inch.**

**20/5 - 3/32 inch.**

**20/4, 3, 2, 1... Letters are smaller. Very clear vision.**

**Standing farther away and seeing the letters clear;**

**Example 40/5; standing 40 feet away and seeing the 20/5, 3/32 inch letter and/or smaller letters clear indicates very clear vision, much clearer than 20/20.**

## Practice Shifting, Central-Fixation, Switching Close and Far on the Eyecharts

### Print the Eyecharts.

Make two identical copies of the chart, place them at close and far distances. Practice Correct Vision Habits: shifting, central-fixation... on the charts once or more per day.

Practice in the sunlight, sun shining over the shoulder onto the charts.

Shifting, switching on the two identical charts improves the memory, imagination, ability to remember, imagine and see the letters clear, improves the brains function of storing clear images of objects in the memory.

The eyecharts become familiar objects.

Familiar objects are relaxing to the mind, eyes and are seen clear. When a letter on the chart is seen clear at a specific distance; all objects at that distance are seen clear.

SWITCH AND SHIFT ON LETTERS ON TWO IDENTICAL EYE CHARTS PLACED AT CLOSE AND FAR/ CLEAR AND UNCLEAR DISTANCES.

SHIFT FROM PART TO PART (DOT TO DOT) ON THE E'S

Practice Correct Vision Habits #1 to 8 on two identical eyecharts;

One chart is placed at a close distance.

The other chart is placed at a far distance. See picture.

Keep one chart at a clear distance.

When looking at a chart, place the chart at eye level, directly in line with the eyes, face.

The letter the eyes look at is placed in the center of the visual field; between the left and right eyes, at eye level.

The far chart is placed about 1 foot to the left or right (alternate) so the close chart does not block the view of the far chart.

When looking at a chart, maintain central-fixation;

when looking at the close chart - stand directly in front of it.

When looking at the far chart - move and stand directly in front of it.

See picture on right.

Shift on letters on the clear and unclear charts and remember, imagine and see the letters dark black and clear.

Practice with the eyes open, closed, open.

Practice with both eyes together, then one eye at a time, then both eyes together again. If vision is less clear in one eye, practice extra time with that eye. Then again a bit with the other eye, then both eyes together again to keep the vision balanced, equal in both eyes.

Keep the letter between the eyes, at eye level, center of the visual field when using both eyes together and when using one eye at a time.

Cover the eye not in use with a eyepatch and keep the eye open under the patch when the eye in use is open. Blink and relax.

Example; Person needs distant vision improvement.

Place one chart at a far, unclear distance.

Place the other identical chart at a clear close distance.

Look at the letter E at the clear close distance; shift on the letter.

Remember, imagine, see the E dark black and perfectly clear.

Do this with the eyes open, then, in the imagination with the eyes closed, then with the eyes open again.

Then; switch to the unclear distant chart.

Look at the identical letter E.

Shift on the E and continue to remember, imagine the E is dark black and clear.

Practice with the eyes open, closed, open.

With practice the distant E will be seen clear.

Switch back to the clear close E.

Repeat; shift on the E, Remember, imagine, see it dark black and clear.

Practice with the eyes open, closed, open.

Looking at the clear close E reinforces the clear image of the E in the brain/memory and helps the brain and eyes work together to produce a clear image of the E when it is seen at the far distance.

Switch back to the E at the far distance.

Shift on it, remember, imagine and see it dark black and clear.

Blink, breathe, relax.

Practice switching, shifting on the close and far E's with both eyes together, then one eye at a time, then both eyes together again for perfect equally clear 20/20 and clearer vision in the left and right eyes at close and far distances. Example: Both eyes together, then one eye at a time: start with either eye: left, then right, then left, right... If vision is less clear in one eye, practice extra time with that eye. Then; end with both eyes together again.

Allow the eyes, head/face, neck and body to relax, move freely when looking at the letters. Relaxation and movement bring clear vision.

Eye, head/face, neck, body immobility, tension, staring, squinting, straining, trying hard to see the letters clear produces unclear vision.

Practice on other letters.

Practice on smaller letters.

Practice at a variety of close, middle, far distances for clear vision at all distances.

Practice on two identical fine print charts with medium, small, smaller, and fine print size letters.

Place the charts at two different close distances.

**Memorize the letters on the chart.** Memorizing the letters causes the chart to become a familiar object, something that is easy to see. **Familiar objects** relax the mind, eyes and activate clear vision.

When the brain memorizes the letters, becomes familiar with them, there is not any effort to see them, mental strain and eyestrain are avoided, the mind/brain, eye muscles, eyes stay relaxed when viewing the chart and the letters are seen clear. This relaxation and clear vision continues when looking at other objects.

When taking an eye test at the eye doctors office, the patient is often hurried, pressured to see the letters on a unfamiliar eyechart clear.

This causes temporary mental strain, leads to squinting, staring, effort to see the letters. This causes temporary eye muscle tension, slightly altered eye, cornea shape with incorrect focus of light rays in the eye causing temporary blur that results in a unnecessary prescription for eyeglasses and over-corrected lenses that are too strong and cause increased eye muscle tension, abnormal eye shape, mental strain, increased blur and future prescriptions for stronger eyeglass lenses.

If the patient knew the letters on the chart and was allowed to relax, and use Correct Vision Habits; shifting, central-fixation... on the letters; the mind, eye muscles, eyes would remain relaxed, the letters on the memorized and unfamiliar eyecharts would be seen clear and the eyeglass prescription would be avoided.

Place a familiar eyechart in the home, work, school and shift on the letters occasionally.

Practice all Correct Vision Habits on the letters;

Central-fixation; the letter the eyes are looking at is placed in the center of the visual field; between the eyes, at eye level.

Look at and see one letter darkest black, clearest at a time in the center of the visual field. The letter the eyes are looking at is in the center of the visual field and is clearest.

Other letters on the chart around and away from the letter are in the peripheral field and are less clear.

Avoid staring, squinting, trying hard to see letters clear. Blink, relax and combine shifting with central-fixation;

When looking at a letter; **shift** on it from small part to small part. Move the small exact center of the visual field part to part, (point to point) on the letters. Blink, let the eyes move. Shift relaxed, easy, continually, restful.

See Doctor Bates directions in his articles in the Close Vision chapter; 'The Menace of Large Print' and 'Think Right'.

See the 'Illusion of Oppositional Movement'; the letter appears to move in the opposite direction the eyes move to, a small, quick movement no larger than the size of the letter. 'The Swing.' See Better Eyesight Magazine and Chapter 6 - The Long Swing, Rock, Short Swing.

When reading an eyechart;

Don't spend a long time looking at a letter if it's unclear. Avoid staring, squinting, straining, trying hard to see it. Shift on it, then move, shift to a new letter. Shift on that letter.

Blink, breathe abdominally, relax.

Shift from letter to letter on the chart.

It is ok to stay on one letter if relaxation, eye shifting occurs. Relax, shift point to point-see small parts-let the eyes move on the letter automatically, on their own.

The eyes, head/face, neck and body are relaxed and move freely. Move the head/face and body with the eyes when shifting on a letter and from one letter to another.

When moving to a new letter, move the head/face, body with the eyes and look/face directly at the letter.

The center of the visual field is clearest. The center of the visual field moves with the eyes from letter to letter, placing each letter the eyes look at, one letter at a time, in the center of the visual field, keeping each letter perfectly clear.

The exact center of the visual field is most clear; place the part of the letter the eyes look at in the exact center of the visual field.

Shift the eyes (visual attention) from small part to small part, moving the small exact center of the visual field from small part to small part (point to point), seeing one small part (point) of the letter darkest black, clearest at a time in the exact center of the visual field. (The part (point) of the letter the central field is on, moving upon/over is clearest while the central field is on that part.)

Practice on small and fine print letters.

The exact center of the visual field; produced by the fovea centralis in the center of the macula, in the center of the eyes retina can be seen/measured by looking at a capitol letter E, 3/8" high, 20/20 line of the distant eyechart, from 20 feet away.

When looking directly at the E, the E occupies space in the center of the visual field produced by the macula and fovea. When looking at a small part of the E (Example; a part in the center of the E), that small part is in the exact center of the visual field produced by the fovea.

+Light rays from this part of the E focus on the center of the fovea when looking at this part, placing it in the center of the visual field.

+Light rays from other areas of the center of the visual field focus on the macula around the fovea.

+Light rays away from the E in the peripheral field of vision focus on the peripheral field of the retina around/away from the fovea and macula.

The fovea (especially the center of the fovea) produces the clearest vision, clearer than 20/20.

The outer fovea and macula produce very clear vision, clearer than 20/20, but not as perfect as the center of the fovea.

The peripheral field of the retina produces less clear vision.

The far outer peripheral field is the most unclear.

See a letter clear by placing it in the center of the visual field and then;

use the exact center of the visual field; place one small part of the letter at a time in the exact center of the visual field and see it darkest black and clearest.

Avoid staring; always shift the eyes to prevent staring, immobility; shift/move the eyes/visual attention (exact center of the visual field) from small part to small part on the letter; top to bottom, side to side, corner to corner, middle; shift from small part to small part in any direction on the letter.

**Example;** shift from dot to dot on the letter E. See picture on page 148.

As the eyes/exact center of the visual field move from part to part (dot to dot); see each part, one small part (dot) at a time darkest black, clearest in the exact center of the visual field.

The entire visual field moves with the eyes as the eyes shift from part to part;

### Example;

Looking at the small part (dot) in the middle of the E.

This part is in the exact center of the visual field and is darkest black and clearest. All other parts are in the peripheral field and are less clear.

Now; shift from that small part in the middle of the E to a small part (dot) on the far edge of the top right side. The small part on the top right is now in the exact center of the visual field, its light ray is focusing on the fovea and it is seen darkest black and clearest.

The previous part and all other parts of the E are in the peripheral field and less clear.

Shift to a new small part; that new part is now in the exact center of the visual field and is darkest black and clearest. Blink.

The eyes can shift to a new part each second, fraction of a second, but, in that short time that a part is in the exact center of the visual field, it is seen darkest black and clearest. This is central-fixation.

When the eyes see the part/area of visual attention with the exact center of the visual field, central-fixation, the exact center is very clear, much clearer than 20/20, and the outer center of the visual field is also very clear, clearer than 20/20 and the peripheral field is normally less clear but is at its maximum clarity.

Seeing clear with central-fixation improves clarity and function of the entire visual field.

### When the mind, body, eyes are relaxed the letters are clear.

Do the rock and long swing in front of the eyechart and do not try to see any letters clear. Just relax, rock or swing left and right and notice the soothing oppositional movement of the chart;

When the eyes, head/face, body swing left <; the chart appears to move right >.

When the eyes, head/face and body swing right >; the chart appears to move left <.

See chapter 6- rock, long swing.

Relax and rock or swing left and right without trying to see the letters.

Then, stop moving left and right. (Some small relaxed movement can be maintained.)

Look at the chart and shift on a letter for a second or two. Blink, breather, relax.

**ROCK LEFT AND RIGHT IN FRONT OF THE CHART  
RELAX, DONT TRY TO SEE THE LETTERS CLEAR**

**ROCK LEFT**

**ROCK RIGHT**

### 'The Short Swing'

See the 'Illusion of Oppositional Movement' of the letter when the eyes shift on it;

+Shift from the left side of the letter to the right side > ;

the letter appears to move 'Swing' to the left <.

+Shift from the right side of the letter to the left side < ;

the letter appears to move 'Swing' to the right >.

Shift up, down, any direction and see the letter appear to move in the opposite direction the eyes/visual attention move to.

Practice shifting and seeing oppositional movement on large, medium, small and fine print letters at close, middle and far distances.

The movement of the letter is short, less than the width of the letter.

Blink and relax.

Seeing oppositional movement of the letter relaxes the mind and eyes, improves the clarity of vision.

Practice shifting on the letter and seeing the illusion of oppositional movement with the eyes open, then in the imagination (use memory, imagination) with the eyes closed, then with the eyes open again.

The long swing and rock are longer movements of the eyes, head, body and produce a longer (swing) appearance of oppositional movement.

Shifting on a small letter produces a smaller oppositional movement, a small Short Swing.

With practice, smaller shifts, on small letters, with a small appearance of oppositional movement Short Swing of the letter can be done. This greatly improves shifting, central-fixation and produces very clear vision. Short, small and tiny shifts, swings produce very clear vision, clearer than long, larger shifts, swings. All shifts, swings activate relaxation, movement and improve the vision.

Next; return to the rock or long swing.

The rock, long swing keeps the mind, body, neck, eyes relaxed, keeps the eyes shifting and vision clear. Stop rocking, swinging left and right every once in a while and then, shift on the letters on the chart again. Notice they are seen clear when the mind/eyes are relaxed and there is no effort to see.

#### **Shorten the rock for a short shift, swing:**

Rock left and right 2 feet, then 1 foot, then 6 inches, 4,3,2,1,  $\frac{1}{2}$ ... inch. Rock with a small movement  $\frac{1}{2}$  - 1 - 2... inches left and right and shift on the letters on the eyechart. See a small swing of oppositional movement of the letters. The rock keeps the eyes, head/face, neck, body relaxed, moving when looking at a letter. This prevents staring and blur. The small shift, swing also produces clear vision.

Practice Dr. Bates method of 'Flashing' the Letters; looking at, shifting on a letter for only a fraction of a second, then looking away to a different letter or object, shift on that object, then return to the letter, shift on it, fraction of a second, then look away, return, look away...

This prevents effort to see, prevents strain and blur; there is not enough time to strain, try to see any object so relaxation is maintained.

The normal eye moves continually, restful, shifting easy from point to point.

#### **Practice The Long Swing with 2 Identical Eyecharts: Flashing, Shifting for a 'Fraction of a Second' on letters on the Eyecharts:**

**The Long Swing with Two Eyecharts**

Identical eyecharts placed on left and right side of the body.

Swing and turn left and right and 'Flash' glance at, shift on a letter on the eyechart for a 'fraction of a second'.

Swing, turn left and 'flash' a letter on the left chart: Blink and shift quickly, easy on the letter. Do not stop swinging.

Swing and turn right and flash a letter on the right chart.

Keep swinging left and right, glancing at the letters. Relax, no effort to see - vision becomes clear.

Place 2 identical eyecharts on the left and right sides of the body.

Swing left and right and Flash a letter on the eyechart for a fraction of a second;

+Swing left < ; shift on, flash the letter for a fraction of a second on the left chart. Blink.

+Swing right > ; shift on, flash the identical letter for a fraction of a second on the right chart. Blink.

Then swing back to the left side, flash the same letter again... Repeat right, left, right, left...

Do this without stopping; keep moving, swinging left and right. Do not stop swinging when looking at the letter. The eyes, head/face and body move, swing and turn left and right together, at the same time, in the same direction. See The Long Swing.

The continual movement keeps the eyes, mind, body relaxed, left and right brain hemispheres integrated. The very short time the eyes, head, body are facing the chart prevents strain, staring at the letter. The eyes shift on the letter quick, easy, do not try to see it clear. Relaxation occurs and vision becomes clear. Practice on identical letters, then on any letters, then on smaller letters.

'Flashing the letters' = Shifting on a letter for a fraction of a second produces a 'Flash' of clear vision. The flash of clarity may last only a second but with practice, maintaining relaxation, the flashes occur more often, last longer, and vision remains clear.

**Practice palming, covering the eyes, then reading, flashing the letters on the eyechart.** Palming chapter 1.

- +Palm for a while and relax.
  - +Uncover and open the eyes and look at a letter on the chart.
  - +Shift on the letter for only a second or fraction of a second.  
No effort to see clear.
  - +Then cover the eyes and palm again. Think pleasant thoughts. Remember, imagine shifting on the letter and see it dark black and clear in the mind. See the mental picture of the letter show oppositional movement as the eyes shift on the image of the letter.
  - +Uncover, open the eyes and shift on the letter again, fraction of a second.
  - +Palm again.
  - +Repeat palming and shifting on the letter (flashing the letter) for a fraction of a second.
- This method keeps the eyes, mind relaxed, prevents effort to see, mental, visual strain and blur. Flashes of clear vision will occur. When relaxation of mind, eyes continues, the vision, letters remain clear.

Rock, sway the body left and right in front of the eyechart again and see the chart, letters move, swing in the opposite direction.

Then; Reduce the length of the rock to 2-4 inches, moving left and right and shift part to part on a letter. Let the eyes move freely to another letter, then another as the body, head, eyes move left and right. No effort to see. Just relax, shift, blink, breathe abdominally.

Rock up and down 1-2 inches. Rock on the feet 1-2 inches forward and backward.

**Click the links for YouTube Videos teaching Natural Vision Improvement with Eyecharts.**

The pothooks eyechart is designed for children, adults that have not yet learnt to read the alphabet. The person points their hand in the direction the E is pointing.

Familiar objects relax the mind, eyes and keep the vision clear. This eyechart is easy to see clear because it is a familiar object: the person knows that every letter on the chart is an E. This makes it easier, more relaxing to look at the different size unclear E's and use the memory and imagination to see the E's clear: the person only needs to shift on the E, guess, imagine which way the E is pointing to see it clear. When the brain remembers, imagines a clear, dark black letter E and guesses, imagines the E pointing in the correct direction; the brain, eyes relax, the brain directs the eye muscles, eyes to move, shift correct, directly on the letter E and the E is seen clear.

If the person guesses an incorrect direction, the E remains unclear because the eyes, brain are trying to shift on, see an incorrect image, trying to shift, move the eyes along areas of the white page away from the E. See the Pothooks Eyechart on the right.

Read another example of guessing with the memory and imagination; looking at, guessing the # 7 on a bus; chapter 9 - Memory and Imagination.

**Shift top and bottom, left and right on the E. (Shift dot to dot). Blink.**

Flash a letter -  
 +Shift on the E for a fraction of a second then  
 +look away from it to another object or close the eyes, palm and remember the E, shift on it in the mind. Or just think any pleasant thoughts with the eyes closed.  
 +Open, shift on the E fraction of a second,  
 +Close, repeat...

+Use the memory, imagination:  
 Remember, imagine the E is clear when the eyes are open and when closed. Practice on any objects, at any distance.

- 7-Building The point regarded changes rapidly and continuously.
- 8-Building The point regarded changes rapidly and continuously.
- 9-Building The point regarded changes rapidly and continuously.
- 10-Building The point regarded changes rapidly and continuously.

It is impossible to read fine print without relaxing. Therefore the reading of such print, contrary to what is generally believed, is a great benefit to the eyes. Persons who can read perfectly fine print, like the above specimen, are relieved of pain and fatigue while they are doing it, and this relief is often permanent. Persons who cannot read it are benefited by observing its blackness, and remembering it with the eyes open and closed alternately. By bringing the print so near to the eyes that it cannot be read pain is sometimes relieved instantly, because when the patient realizes that there is no possibility of reading it the eyes do not try to do so. In myopia, however, it is sometimes a benefit to strain to read fine print. Persons who can read fine print perfectly imagine that they see between the lines streaks of white whiter than the margin of the page, and persons who cannot read it also see these streaks, but not so well. When the patient becomes able to increase the vividness of these appearances (see *Halos*, February number) the sight always improves.

NEW YORK, N. Y.

Do you read imperfectly? Can you observe then that when you look at the first word, or the first letter, of a sentence you do not see best where you are looking; that you see other words, or other letters, just as well as or better than the ones you are looking at? Do you observe also that the harder you try to see the worse you see?

Now close your eyes and rest them, remembering some color, like black or white, that you can remember perfectly. Keep them closed until they feel rested, or until the feeling of strain has been completely relieved. Now open them and look at the first word or letter of a sentence for a fraction of a second. If you have been able to relax, partially or completely, you will have a flash of improved or clear vision, and the area seen best will be smaller.

After opening the eyes for this fraction of a second, close them again quickly, still remembering the color, and keep them closed until they again feel rested. Then again open them for a fraction of a second. Continue this alternate resting of the eyes and flashing of the letters for a time, and you may soon find that you can keep your eyes open longer than a fraction of a second without losing the improved vision.

If your trouble is with distant instead of near vision, use the same method with distant letters.

In this way you can demonstrate for yourself the fundamental principles of the cure of imperfect sight by treatment without glasses.

If you fail, ask someone with perfect sight to help you.

## FOREWORD

**W**HEN the United States entered the European war recruits for general military service were required to have a visual acuity of 20/40 in one eye and 20/100 in the other.<sup>1</sup> This very low standard, although it is a matter of common knowledge that it was interpreted with great liberality, proved to be the greatest physical obstacle to the raising of an army. Under it 21.68 per cent. of the registrants were rejected, 13 per cent. more than for any other single cause.<sup>2</sup>

Later the standard was lowered<sup>3</sup> so that men might be "unconditionally accepted for general military service with a vision of 20/100 in each eye without glasses, provided one eye was correctible to 20/40. For special or limited service they might be accepted with only 20/200 in each eye without glasses, provided one was correctible to 20/40. At the same time a great many defects other than errors of refraction were admitted in both classes, such as squint not interfering with vision, slight nystagmus, and color blindness. Even total blindness in one eye was not a cause for rejection in the limited service class, provided it was not due to progressive or organic change, and the vision of the other eye was normal. Under this incredible standard eye defects still remained one of three leading causes of rejection.

## THE MEMORY CURE

When the sight is perfect, the memory is also perfect, because the mind is perfectly relaxed. Therefore the sight may be improved by any method that improves the memory. The easiest thing to remember is a small black spot of no particular size and form; but when the sight is imperfect it will be found impossible to remember it with the eyes open and looking at letters, or other objects with definite outlines. It may, however, be remembered for a few seconds or longer, when the eyes are closed and covered, or when looking at a blank surface where there is nothing particular to see. By cultivating the memory under these favorable conditions, it gradually becomes possible to retain it under unfavorable ones, that is, when the eyes are open and the mind conscious of the impressions of sight. By alternately remembering the period with the eyes closed and covered and then looking at the Snellen test card, or other letters or objects; or by remembering it when looking away from the card where there is nothing particular to see, and then looking back; the patient becomes able, in a longer or shorter time, to retain the memory when looking at the card, and thus becomes able to read the letters with normal vision. Many children have been cured very quickly by this method. Adults who have worn glasses have greater difficulty. Even under favorable conditions, the period cannot be remembered for more than a few seconds, unless one shifts from one part of it to another. One can also shift from one period, or other small black object, to another.

## "PAGE TWO"

ON page two of this magazine are printed each month specific directions for improving the sight in various ways. Too many subscribers read the magazine once and then mislay it. We feel that at least page two should be kept for reference.

When the eyes are neglected the vision may fail. It is so easy to forget how to palm successfully. The long swing always helps but it has to be done right. One may under adverse conditions suffer a tension so great that the ability to remember or imagine perfectly is modified or lost and relaxation is not obtained. The long swing is always available and always brings sufficient relief to practice the short swing, central fixation, the perfect memory and imagination with perfect relief.

*Be sure and review page two frequently; not only for your special benefit but also for the benefit of individuals you desire to help!*

Persons with imperfect sight often have difficulty in obtaining relaxation by the various methods described in the book and in this magazine. It should be emphasized that persons with good vision are better able to help others than people who have imperfect sight or wear glasses. If you are trying to cure yourself avoid people who wear glasses or do not see well. Those individuals are always under a strain and the strain is manifested in their face, in their voices, in their walk, the way they sit, in short in everything that they do.

Strain is contagious. Teachers in Public Schools who wear glasses are a menace to their pupils' sight. Parents who wear glasses or who have imperfect sight lower the vision of their children. It is always well when treating children or adults to keep them away from people with imperfect sight.

### REASON AND AUTHORITY

Some one—perhaps it was Bacon—has said: "You cannot by reasoning correct a man of ill opinion which by reasoning, he never acquired." He might have gone a step farther and stated that neither by reasoning, nor by actual demonstration of the facts, can you convince some people that an opinion which they have accepted on authority is wrong.

A man whose name I do not care to mention, a professor of ophthalmology, and a writer of books well known in this country and in Europe, saw me perform an experiment upon the eye of a rabbit which, according to others who had witnessed it, demonstrated beyond any possibility of error that the lens is not a factor in accommodation. At each step of the operation he testified to the facts; yet at the conclusion he preferred to discredit the evidence of his senses rather than accept the only conclusion that these facts admitted.

First he examined the eye of the animal to be experimented upon with the retinoscope and found it normal, and the fact was written down. Then the eye was stimulated with electricity, and he testified that it accommodated. This was also written down. I now divided the superior oblique muscle, and the eye was again stimulated with electricity.

## Better Eyesight

A Monthly Magazine  
Devoted to the Prevention  
and Cure of Imperfect  
Sight without Glasses

Published by the Central Fixation Company, 300 Madison Ave., New York, as the official organ of the BETTER EYESIGHT LEAGUE, a national organization to relieve the suffering and discomfort of those afflicted with imperfect eyesight, to disseminate the knowledge of the scientific cure and prevention of imperfect sight without the use of glasses, and to promote further research and investigation into the causes for imperfect eyesight and its improvement without the use of artificial lenses.

W. H. BATES, M. D., Editor

VOL. VII. JULY, 1922 No. 1

### THE STORY OF VIOLET

By W. H. BATES, M. D.

*Just what, in simple words, is Central Fixation?  
If you will read this story of a ten-year-old girl  
who discovered it for herself you will know,  
not in terms of theory or in scientific phrases,  
but in practical simplicity.*

SOME years ago a young girl, aged 10, was brought to me for the cure of imperfect sight and squint. She was wearing quite strong glasses for relief. The right or squinting eye, even with her strong glasses, had very poor vision. The best she could see with this eye with or without glasses was counting fingers at about three feet. Looking straight ahead of her with this squinting eye, with the other eye covered, everything was visible and, she said, perfectly dark, and what she did see at any time with this eye was off to one side. She was unable to read with this eye with or without her glasses.

3

## MAKE YOUR SIGHT WORSE

Strange as it may seem there is no better way of improving the sight than by making it worse. To see things worse when one is already seeing them badly requires mental control of a degree greater than that required to improve the sight. The importance of these facts is very great. When patients become able to lower their vision by conscious staring, they become better able to avoid unconscious staring. When they demonstrate by increasing their eccentric fixation that trying to see objects not regarded lowers the vision, they may stop trying to do the same thing unconsciously.

What is true of the sight is also true of the imagination and memory. If one's memory and imagination are imperfect, they can be improved by consciously making them worse than they are. Persons with imperfect sight never remember or imagine the letters on the test card as perfectly black and distinct, but to imagine them as grey and cloudy is very difficult, or even impossible, and when a patient has done it, or tried to do it, he may become able to avoid the unconscious strain which has prevented him from forming mental pictures as black and distinct as the reality.

To make imperfect sight worse is always more difficult than to lower normal vision. In other words, to make a letter which already appears grey and indistinct noticeably more cloudy is harder than to blur a letter seen distinctly. To make an imperfect mental picture worse is harder than to blur a perfect one. Both practices require much effort, much hard disagreeable work; but they always, when successful, improve the memory, imagination and vision.

## REST

All methods of curing errors of refraction are simply different ways of obtaining rest.

Different persons do this in different ways. Some patients are able to rest their eyes simply by closing them, and complete cures have been obtained by this means, the closing of the eyes for a longer or shorter period being alternated with looking at the test card for a moment. In other cases patients have strained more when their eyes were shut than when they were open. Some can rest their eyes when all light is excluded from them by covering with the palms of the hands; others cannot, and have to be helped by other means before they can palm. Some become able at once to remember or imagine that the letters they wish to see are perfectly black, and with the accompanying relaxation their vision immediately becomes normal. Others become able to do this only after a considerable time. Shifting is a very simple method of relieving strain, and most patients soon become able to shift from one letter to another, or from one side of a letter to another in such a way that these forms seem to move in a direction opposite to the movement of the eye. A few are unable to do this, but can do it with a mental picture of a letter, after which they become able to do it visually.

Patients who do not succeed with any particular method of obtaining rest for their eyes should abandon it and try something else. The cause of the failure is strain, and it does no good to go on straining.

### EXPERIENCES WITH CENTRAL FIXATION

By M. H. STUART, M.D.

Moultrie, Ga.

*We are greatly indebted to Dr. Stuart for sending us this remarkable story of his own cure and that of his patients, all of which was accomplished without personal assistance by means of the information presented in this magazine.*

Some sixteen years ago, when working as a stenographer, I developed indigestion and became extremely nervous, one of my symptoms being a tension in the spinal cord between the shoulder blades which was extremely uncomfortable. In the late afternoon and evening I would become so nervous that I could scarcely sit still, and I have walked five miles into the country and back again to get relief. I tried dieting for the indigestion, but after two months failed to get any relief. A medical student then suggested that the trouble might be due to my eyes. I went to an oculist, who fitted me with glasses, and all my troubles ceased.

The glasses given to me were convex 0.25, axis 90. A few years later, when I was in New York doing post-graduate work at the Polyclinic, they were changed to concave

### HOW I HELPED OTHERS

By VICTORIA COOLIDGE

When I had become able to read without glasses, and my headaches had become less and less frequent, and less severe each time, I was so enthusiastic over my experience that I was anxious to help others. My brother was my first patient. He was so much interested in what had been done for me that he wanted to try it himself; but I never dreamed of being able to help him, because his eyes were almost as bad as my own had been, his glasses being: right eye convex 3.25 D.S.; left eye, convex 3.75 D.S. combined with 0.50 D.C., 180 degrees. However, I knew the treatment could do no harm, so I decided that I would try to show him as nearly as I could what Dr. Bates had done for me. Imagine my surprise, then, when I found that he, too, by holding the fine print six inches from his eyes and looking alternately at the top and bottom of the letters, became able to read it just as I had become able to do so. He proved to be a model pupil as soon as he had demonstrated to his own satisfaction that he must leave off his glasses all the time if he wanted to make any appreciable progress. He has now done without them for about a year, and has made remarkable prog-

## Go to the Movies

(Editor's Note.—Recently a great many letters have come from patients and others asking if the movies were injurious to the eyes. For the benefit of these inquirers we are reprinting an article which appeared in this magazine in October, 1920.)

Cinematograph pictures are commonly supposed to be very injurious to the eyes, and it is a fact that they often cause much discomfort and lowering of vision. They can, however, be made a means of improving the sight. When they hurt the eyes it is because the subject strains to see them. If this tendency to strain can be overcome, the vision is always improved, and if the practice of viewing the pictures is continued long enough, nearsight, astigmatism and other troubles are cured.

If your sight is imperfect, therefore, you will find it an advantage to go to the movies frequently and learn to look at the pictures without strain. If they hurt your eyes look away to the dark for a while, then look at a corner of the picture; look away again, and then look a little nearer to the center; and so on. In this way you may soon become able to look directly at the picture without discomfort. If this does not help, try palming for five minutes or longer. Dodge the pain, in short, and prevent the eyestrain by constant shifting, or by palming.

### Cataract

By W. H. BATES

SINBAD the sailor told many stories of his voyages which have pleased some adults and many children. I wish to maintain that some of his experiences were true while many were not. On one of his voyages, when sailing in the tropics, a violent storm struck the ship and he was wrecked on the shores of an island in the Pacific Ocean. As usual, most of the sailors were drowned but Sinbad lived to return home and tell of the wonders he had seen.

It was related by him that the island was frequented by goats who were blind for a variable length of time. After a few days or weeks many of them recovered their sight, being cured in some way by a thorn bush which had large thorns. Sinbad watched them closely and discovered that each goat pushed each blind eye directly onto one of these thorns. After a few efforts the goat became able to see. How was it accomplished?

The cause of the blindness was the presence of an opaque body behind the pupil. This opaque body is a cataract. There are numerous operations for the cure of cataract but all are planned to move it to one side, above or below the optic axis so that the pupil appears perfectly clear and permits good sight. Eye doctors dur-

## Perfect Sight Without Glasses

By W. H. BATES, M.D.

The author of this book presents evidence that all errors of refraction are caused by strain—and cured by rest and relaxation.

The complete method of treatment is described so clearly that the reader can usually discard his glasses and improve his vision.

For sale at this office and at leading bookstores.  
Price \$3.00 postpaid.

### METHODS OF TREATMENT described in

Stories from the Clinic

By EMILY C. LIERMAN

This book fully explains the author's experiences in treating clinic patients and her application of Dr. Bates' method of treatment to each individual case.

"Stories from the Clinic" is a contribution to the practice of Ophthalmology

## Stop Staring

It can be demonstrated by tests with the retinoscope that all persons with imperfect sight stare, strain, or try to see. To demonstrate this fact:

Look intently at one part of a large or small letter at the distance or nearpoint. In a few seconds, usually, fatigue and discomfort will be produced, and the letter will blur or disappear. If the effort is continued long enough, pain may be produced.

To break the habit of staring:

- (1) Shift consciously from one part to another of all objects regarded, and imagine that these objects move in a direction contrary to the movement of the eye. Do this with letters on the test card, with letters of fine print, if they can be seen, and with other objects.
- (2) Close the eyes frequently for a moment or longer. When the strain is considerable, keep the eyes closed for several minutes and open them for a fraction of a second—flashing. When the stare is sufficient to keep the vision down to 2/200 or less, palm for a longer or shorter time; then look at the card for a moment. Later mere closing of the eyes may afford sufficient rest.
- (3) Imagine that the white openings and margins of letters are whiter than the rest of the background. Do this with eyes closed and open alternately. It is an interesting fact that this practice prevents staring and improves the vision rapidly.

### Imagination Essential to Sight

By W. H. BATES, M.D.

**I**T IS a well-known fact that vision is a process of mental interpretation. The picture which the mind sees is not the impression on the retina, but a mental interpretation of it. To the mind objects seen appear to be in an upright position, but the picture on the retina is upside down. When the sight is normal the margins and openings of black letters on a white card appear whiter than the rest of the card, but this, of course, is not the fact, the whole background being of the same whiteness. One may seem to see a whole letter all alike at one time, but, as a matter of fact, the eye is shifting rapidly from one part to another. The letter may also seem to move although it is stationary.

When the vision is imperfect the imagination is also imperfect. The mind, in short, adds imperfections to the imperfect retinal image. A great part of the phenomena of imperfect sight are, therefore, imaginary and not in any way to be accounted for by the derangement of the visual apparatus. The color, size, form, position and number of objects regarded are altered, and non-existent objects may be seen. Some persons with imperfect sight literally see ghosts. A boy, or a grown person either, in a

Eye socket, bones, eye, eye muscles, optic nerve.

The eye socket is composed of bone segments. These are connected with the skull bones. Eye muscles attach to the skull bones in the back of the eye socket. Eye muscle nerves, the optic nerve, blood, lymph vessels also travel from the spinal cord/brain stem, brain, neck through the eye socket, skull bones. Unclear vision is usually caused by mental strain, tense, incorrect use of the eyes, 'staring-squinting', incorrect posture, stress, negative thoughts, emotions. These can cause: outer and inner eye muscle tension, abnormal eye shape, disrupted focus of light rays in the eye, tension, abnormal pressure on/in the eye, impair circulation in the eye, resulting in unclear vision... Extreme neck, shoulder muscle tension, incorrect posture places pressure, tension, pulling on the nerves, blood, lymph vessels that travel from the spine, neck, brain stem to the eyes, eye muscles, retina, lens, brain. Neck muscle tension also travels directly up into the eye muscles. These conditions cause: tension, abnormal pressure on/in the eye, optic nerve, eye muscle nerves, retina, lens, outer and inner eye muscle tension/dysfunction, abnormal eye shape, disrupts focus of light rays in the eye, resulting in: unclear vision, astigmatism, crossed, wandering eyes, imperfect convergence, divergence, accommodation, un-accommodation, cataracts and other conditions. Circulation of blood, oxygen, lymph, fluid, tears... in the eye is impaired. Sinus, tension, migraine headaches, disrupted ear function can also occur and affect the vision. Wearing eyeglasses creates, increases, maintains all of these causes and resulting conditions.

The Bates Method of Natural Eyesight Improvement, relaxation of the mind, neck, body, eye muscles, eyes, good posture returns the eyes to normal function with 20/20 and clearer close & distant vision. Wandering, Crossed Eyes, Astigmatism are corrected. Cataracts and other eye conditions are reversed, removed without use of eyeglasses, eye surgery, drugs.

COLOR BREATHING RELAXATION CHART

Practice Abdominal Breathing, Palming, Color Visualization, Deep Relaxation and Correct Vision Habits in the Alpha, Theta and Delta brain wave states with the Color Breathing Relaxation Chart to relax the mind, eyes, eye muscles, neck and body for clear eyesight. Notice that eyesight is clear when the mind, body, eyes are relaxed in a positive state. See chapter 22-23.

Switch and shift on objects at close and far distances for 20/20 and clearer eyesight at all distances, close and far. See Chapters 11-13.

A percent of profits from the sale of this book is donated to the blind, visually impaired: Guide Dog Schools, free Natural Eyesight Improvement Training.

This Book Teaches the Original and Modern Bates Method of Natural Eyesight Improvement Discovered by Ophthalmologist Dr. William Horatio Bates. The Clarity of Eyesight can be Improved to 20/20 and Clearer at All Distances.

NORMAL ROUND EYE SHAPE WITH CORRECT FOCUS OF LIGHT RAYS ON THE RETINA. EYESIGHT IS CLEAR.

The Bates Method of Natural Eyesight Improvement relaxes the mind, eye muscles, eyes, body, (entire visual system), returns the eye muscles, eyes to normal function, movement, coordination and activates, perfects; the normal function of the eyes: Saccadic Shifting Eye Movements, Central Fixation, Perfect Convergence, Accommodation: clear vision when looking at close distances, Un-Convergence (Divergence) Un-Accommodation: clear vision for far distances, Left and Right Brain Hemisphere Activation and Integration, Memory and Imagination, Positive Thinking, Emotions, Correct Posture, Neck, Shoulder Relaxation and all functions of the visual system.

Color treatment, Full Spectrum Sunlight, Physical Movement Activities, Acupressure Points, Physical Therapy, Improved Circulation to the head, brain, ears, eyes, eye muscles, retina, lens, cornea, Energy Strengthening-Circulation, EFT, Healthy Diet for Healthy Eyes and other natural activities are practiced. Learn how to permanently discontinue the use of eyeglasses.

Relaxation of the mind, body, neck, eye muscles, eyes, practicing, activating healthy correct vision habits (normal, relaxed eye function) and other natural treatments keeps the eye in normal shape with correct focus of light rays in the eye, on the retina for clear vision. Eye pressure returns to normal. Tension, strain is removed from the eyes. Health and function of the eyes, retina, lens, cornea, optic nerve, all parts of the eye returns to normal.

Saccadic Shifting - perfect, relaxed eye movements, including tiny microscopic movements are re-activated resulting in clear eyesight (clearer than 20/20: 20/15, 20/10...) at all distances, close and far, day and night.

Eyeglasses, bifocals, contact lenses, sunglasses, tinted/colored lenses, eye cornea laser surgery, all prescription and non-prescription drugs cause and increase vision impairment: blur, astigmatism, impairs the health, function of the eyes; results in cataracts, detached retina, glaucoma, cornea ulcers, macula degeneration and other eye, vision impairment.

The Bates Method of Natural Eyesight Improvement produces clear eyesight and healthy eyes.

Do it Yourself-Natural Eyesight Improvement

## Author's Will

June 23<sup>rd</sup>, 2011

I, Mary Iva Oliver of Worcester, MA and South San Francisco, CA being of clear, healthy mind leave the following Natural Eyesight Improvement Books, Website to;

David Kiesling, Owner, Webmaster of [www.iblindness.org](http://www.iblindness.org) - California, USA

I am placing David in my will because I know I can trust him to keep The Bates Method, Natural Eyesight Improvement low cost and free to the public.

Other People that I have contacted only want money from selling the books, and/or are not interested in Natural Eyesight Improvement. I suspect these people will raise the book prices, remove all the free books from the website. A few honest people fear they will be sued by the AMA, Optical Businesses, Eye Surgeons for teaching Natural Eyesight Improvement so they declined ownership. (In modern times, this is becoming rare, but suits still occur by corrupt businesses...)  
Bates Method, Natural Eyesight Improvement Teachers prefer to create their own books.

All people, regardless of financial state must have access to free and low cost Natural Eyesight Improvement! David cares about the people, Natural Eyesight Improvement Students. He has proved this by maintaining his Website, Forum and Teaching The Bates Method Free for 11 years.  
Many treatments in my books are a result of learning from his website, Forum.

On my death or severe disability; I leave David Kiesling all rights to my Paperback books and Kindle, PDF E-books; This includes the books; 'Do It Yourself - Natural Eyesight Improvement - Original and Modern Bates Method with Better Eyesight Magazine,' & 'Better Eyesight Magazine by Ophthalmologist William Horatio Bates - July, 1919 to June, 1930' & 'Better Eyesight Magazine Illustrated with 500 Pictures' & Better Eyesight Magazine Original Antique pages'. There are more books; all are stored, distributed by; Amazon.com Createspace, Kindle, Payloadz Bookstore and Lulu publishing. I will work with these publishers and a Lawyer to transfer my Kindle, Createspace, Payloadz, LULU and Website accounts, passwords to David.

I also leave David my website; [www.cleareyesight.info](http://www.cleareyesight.info) . He may use profits from book sales to pay for the monthly website fee or, if preferred, attach it as a separate link to his or friends... website to save cost of paying for 2 websites. The entire website is in the Paperback book & Kindle, PDF E-books. The books have the newest upgrades, editions. The website will be upgraded in the future. Adobe Acrobat can create a website copy with full working Navigation bar, all links... then attach it to a website. Like a website within a website. The PDF version of the website also contains the linked navigation bar as a book chapter index.

I ask that if the books continue selling well; please donate a percent of profits to the Guide Dog Schools; (The Seeing Eye, Guiding Eyes For The Blind), Perkins School For The Blind, DAV, ASPCA listed on their page on the website; 'Blind, Visually Impaired Achieve Independence.'

<http://cleareyesight.info/id73.html>

If David prefers not to keep my website running, (or to provide a free PDF copy of it) ; then, anyone can re-publish the website with all rights maintained forever to the public. No-one, except David can own it by copyright, be the only publisher. I know David will pass it on to a trusted soul in the future. Same rule for the books; if David (or a person he designates to sell, distribute) does not sell or give the books free; then, all books are copyright free to the public. Everyone can copy, sell, distribute, give free to the public.

Signed;

Mary Iva Oliver (Writers Pen Name; Clark Night)
